VAGINO-UTERINE PROLAPSE AND ITS EFFECTIVE TREATMENT *

E. E. MONTGOMERY, M.D., LL.D.
Professor Gynecology, Jefferson Medical College; Gynecologist to Jefferson and St. Joseph's Hospital
PHILADELPHIA

Vagino-uterine prolapse is a form of hernia through the vaginal outlet which may involve respectively the bladder and anterior vaginal wall, the anterior vaginal wall or the bladder and the cervix uteri; or the eversion may comprise cervix, or uterus, and the entire vaginal structure. The protrusion of the anterior pelvic segment is frequently a sliding of the bladder, pushing it before the anterior vaginal wall and dragging on the cervix where the uterus is firmly fixed as by firm ligaments and resistant peritoneum. The traction on the cervix causes a hypertrophic elongation of the supravaginal portion of the cervix. The anterior and posterior vaginal walls are attached to the cervix at different levels so that such an elongation may occur in the vesical portion of the cervix with complete eversion of the anterior vaginal wall and the cervix, while the posterior vaginal, remains intact and presents its normal length. Not infrequently, the hernia begins in the posterior wall as a protrusion of the rectum between the levatores ani by which the vagina is protruded or sacculated. Traction is made on the cervix which may lead to hypertrophic elongation, or to displacement of the entire uterus (Fig. 1). Not infrequently, also, the protruding rectum becomes adherent to the edges of the levatores ani and must be separated in order to permit the introduction of sutures for the interposition of the muscles. The prolonged continuance of this form of hernia leads to passive congestion, edema and thickening of the walls. The congested structures have decreased resistance and are exposed to more frequent injury through contact with the patient's clothing, friction against her limbs, soiling with urine and feces and other injuries. Patches of ulceration are frequent and when formed are slow to heal; the uterus is heavy, enlarged and sometimes irreducible; more frequently, however, the traction of the thickened tissues causes elongation of the supravaginal portion of the cervix while the body retains somewhat near its normal situation. In the great majority of cases, this condition occurs in women advanced in life, nearing or having passed the climacteric. In such patients the problem of subsequent gestation is not an essential factor but even in women during the child-bearing period, any operation for the successful retention of the protruding uterus and vagina is inconsistent with the *continuance of procreation. No operative procedure* has been devised for such a condition which will successfully endure the mechanism of a subsequent labor. Indeed, the changes produced in the uterus are such as to render conception improbable, and to make the uterus unable to develop in such a way as to offer a reasonable *probability that the fecundated ovum shall* find a proper soil and secure habitation to ensure completion of the pregnancy. When it is probable procreation will not be successful, there should be no hesitation as to the removal of the uterus. It is difficult to restore a uterus which has undergone elongation of its cervical portion to the proper relation with the other pelvic structures. It is a more or less crippled organ, capable of adding to the unhappiness of the situation.

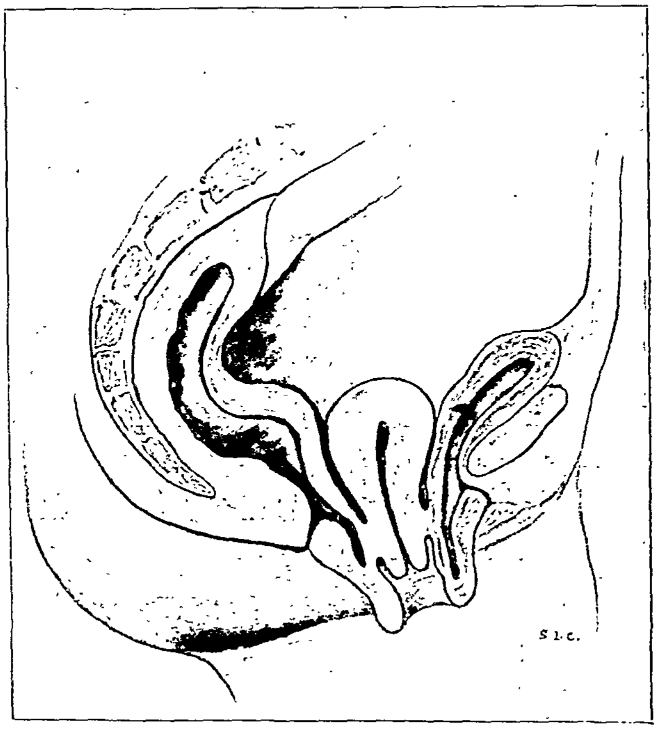

Fig. 1.—Vagino-uterine prolapse.

It is well appreciated that the discomfort and danger to the patient is lessened when the operative procedure can be confined to the vaginal route. The uterus in such cases is a needless organ—yea, worse than needless, a diseased organ—which affords lessened discomfort especially through its removal by the vaginal procedure; the more rapid convalescence and the greater security for permanent recovery *are ample reasons for resort to this* procedure.

The operation is commenced by the removal of a large section of the anterior vaginal wall; the bladder is widely pushed back from the retained portions, and separated from the cervix until the peritoneum is reached and opened. The posterior peritoneum is opened and the uterine and ovarian vessels ligated on either side, the broad ligament stumps held with clamp forceps and the uterus removed. In such cases, the retroperitoneal pouch has dissected downward covering an unusual portion of the anterior rectal surface and dragging down the rectum.

---

* Read in the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

The peritoneum should be stripped off from the prolapsed rectum. when the hemostasis is complete, the recumbent patient should have the pelvis slightly elevated until the intestines slide out of the wound. A suture enters the anterior border of the left broad ligament, gathers up the peritoneum of the bladder, is brought out through the anterior margin of the right broad ligament, when its ends are secured by clamp forceps. A second suture passes through the posterior margin of the ligament and gathers up the peritoneum of the pouch of Douglas which we separated (Fig. 2). A third suture passes beneath the peritoneum of the upper surface of the left ligament, is carried through the wall of the bladder midway between the peritoneal reflexion and the vesical neck (lower if required), emerges from the right broad ligament in a similar manner to its entrance on the left. A fourth suture from the upper surface of the one ligament stump passes through the wall of the rectum from which the peritoneum has been stripped and out through the opposite ligament; each of these sutures has been secured by forceps, preferably by forceps of different sizes so that they can be easily differentiated. The tying of the first two sutures closes the peritoneal cavity. The remaining sutures when secured raise the prolapsing bladder and rectum. The stumps of the broad ligaments are made to overlap each other and the bladder and rectum are secured on their upper surfaces and beneath the peritoneum (Fig. 3). The anterior vaginal sections are secured to the broad ligament stumps and are closed over the bladder by transverse interrupted sutures. Each suture picks up the muscle wall of the bladder, thus obliterating dead space. A pledget of iodoform gauze is packed into the pelvis.

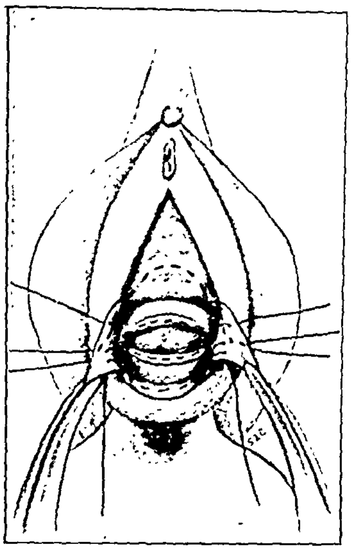

Fig. 2.—Sutures inserted for closing the peritoneum and lifting up the bladder and rectum.

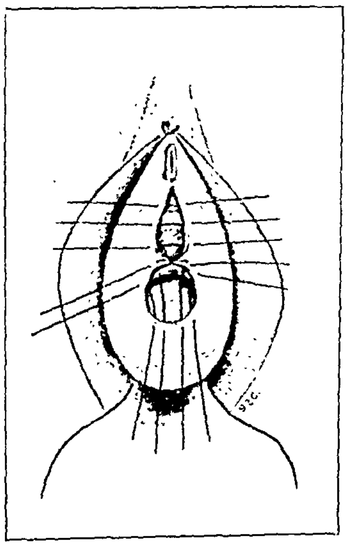

Fig. 3.—Broad ligaments overlapping beneath bladder and rectum. Sutures inserted to close the vaginal walls.

The operation is completed by dissecting a flap from the vulvovaginal margin upward on the posterior vaginal wall, largely by blunt dissection or pressing the tissue away from the vaginal flap with a gauze sponge until a suitable height has been reached, when a triangular portion of this mucous flap is excised. The sutures are so introduced into the edge of the levator ani muscle as to bring the structure from one side in apposition with its fellow in front of the rectum. When thus secured by three or four sutures, the margins of the vaginal walls are united by transverse interrupted sutures. Chromic catgut sutures are employed throughout and no effort is made to remove the sutures.

The operation has the following advantages:

1. The diseased, distorted uterus with its increased weight is removed.
2. Prolapse of both rectum and bladder is prevented inasmuch as they are supported on the upper surface of the broad ligaments.
3. The possibility of protrusion of the rectum, carrying with it the posterior vaginal wall, is obviated by the rectovaginal interposition of the levatores ani muscles.
4. The normal length of the vagina is maintained.

1426 Spruce Street.

PROLAPSE OF THE UTERUS *

FRANKLIN H. MARTIN, M.D.
CHICAGO

We were taught: "Keep the cervix of the uterus in the hollow of the sacrum and the rest of the organ will take care of itself."

This teaching is just as applicable now for prolapse of the uterus in the modern treatment of that condition as it was found for all kinds of displacements of the uterus, when these conditions were treated by pessaries and multitudes of "methods" of surgery.

The most modern and satisfactory operation for extreme descent of the uterus is undoubtedly the Dührssen-Watkins-Wertheim anterior transposition operation. This involves the placing of the fundus beneath the bladder and making a high restoration of the rectovaginal septum. This throws the uterus into extreme anteversion and places its fundus below the bladder—between it and the anterior vaginal wall. This, of necessity, turns the cervix backward and with a fulcrum of the highly restored levator ani muscles to act beneath it, it is still further shunted higher into the hollow of the sacrum with each attempt of the fundus to descend. This position of the uterus blocks the passage and the twisted broad ligaments shorten the central support and the hernia is cured by changing the presenting diameter of its contents.

This operation is ideal in women past the child-bearing period. In extreme cases, it is doubtful if one would not be justified in rendering the woman sterile by interrupting the tubes, in order to make the operation available for prolapse in child-bearing women. This I have done.

Recently, on several occasions, I have modified the steps of the Watkins operation to make it available to younger women.

In the first step of the old operation, after making the longitudinal incision through the anterior vaginal wall in order to elevate the bladder and to expose the fundus for delivery, there are always observed two strong fascial bands extending from the pubis beneath the lateral

---

* Read in the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

walls of the vaginal mucous membrane, which extend to the cervix. They are the stretched-out remains of the pubocervical or the vesical uterine ligaments. The prolapsing bladder has descended between them. By a rapid dissection these fascial bands can be separated from the lateral walls of the vagina and their outer edges will be found to coalesce with the strong middle diaphragm or fascia of the pelvis.

In the operations I have done, after these fascial bands are dissected free, the bladder is carefully elevated to a level of the top of the fundus of the uterus. The cervical ends of these bands are severed, appropriately shortened on their cervical ends, and after being crossed in order to make a support for the bladder, the ends are securely transplanted into the fundus of the uterus just in front of the crest. The vaginal wall is closed, after its superabundance is removed, in a manner to maintain or increase its long diameter, and to eliminate the dead space caused by elevating the bladder.

Previous to this step, the fundus has been exposed, and when the case of prolapse has been a severe one, and the fundus is easily delivered, I examine by inspection, by means of a broad long-bladed retractor placed above the delivered uterus, the sacral folds of peritoneum containing the vestige of the sacro-uterine ligaments. These folds are often easily seen and felt, appearing as long flaccid folds of peritoneum. A pair of rounded, slightly curved, 8-inch artery clamps, guided by sight and touch, are thrust through the base of each broad ligament, on a level of the internal os and from a point in front of the cervix from within the longitudinal vaginal incision, into the culdesac of Douglas. The forceps are then opened in order to enlarge the tunnel through which they pass, and they are each made to grasp the sacro-uterine fold at a point about one-third distance from its uterine end, and this fold is drawn through the route of the forceps on either side of the cervix, while the cervix is pushed upward and backward on the doubled peritoneal fold until the forceps have withdrawn the apices of the two folds to the point of the cervix. The cervix is pushed well back on these folds after the grasp of the forceps is renewed. This not only carries it backward, but upward. The folds of the superabundance of ligament are then securely united in front of the cervix. The appendages of the uterus are inspected and the fundus fixed, as heretofore described.

With this form of operation, a successful result depends much on the form of the perineorrhaphy.

In prolapse cases it is often forgotten that the posterior vaginal wall mucous membrane becomes atrophied in its longitudinal direction. An attempt to restore the cervix to its high position in the hollow of the sacrum will reveal a distinct pull on the cervix on the part of this atrophied vaginal wall. This pull may prove diastrous to the stability of the replaced uterus.

In these same cases, too, the levator ani muscles are defective in effecting their normal support, either because of being torn, because of an undeveloped condition, or because of being displaced laterally by the forces of childbirth. In each of these cases, the anus is unsupported and sags below the normal level, and the lower rectum pushes forward the vaginal mucous membrane in a rectocele.

The perineorrhaphy that I attempt to do in these cases effectually corrects these conditions: that is, it lengthens the posterior vaginal wall and takes the pull off the cervix; it brings together the defective levator ani muscles between the reconstructed vaginal wall and the rectum; it elevates the anus and obliterates the rectocele by elevating the end of the lower bowel; it places the reconstructed levator ani muscles directly beneath the elevated cervix, and thus gives it no opportunity to begin a descent.

I received the idea of this operation in witnessing a somewhat similar procedure at the Mayo Clinic. In its essentials, it is a flap-splitting operation. In detail, with its modifications as I perform it, it is as follows:

The ordinary horseshoe incision is made, extending to the side of the vulva and across the septum between the vagina and anus. The portion of the mucous membrane at the center of the septum is separated from the rectum for about one inch; the remainder of it is allowed to retain its attachment. Then a high dissection is made on either side of the vagina and the vaginal rectal space until the levator ani muscles are definitely exposed. The vaginal mucous membrane flap is now grasped at its middle point with a long pair of forceps, and the free straight border of the vaginal flap is converted into an acute triangle with the central portion grasped by the forceps as the apex and the two sides of the triangle extended longitudinally into the vagina by carrying the portion grasped by the forceps in a direction away from the perineum toward the cervix and the vault of the vagina. This maneuver elevates the lower end of the rectum by the pull on the centrally attached mucous membrane of the vagina and allows the levator ani muscles to be brought together in the central line beneath the elevated rectocele and the extended posterior wall of the vagina. The two sides of the angle of the mucous membrane of the vagina are now united in the middle line, making a seam extending from the new vaginal edge to the elevated tip of the vaginal mucous membrane which constituted the apex of the triangle. The skin over the perineum is next closed by extending the simple catgut suture which closed the longitudinal line in the posterior vaginal wall.

When this operation is done for prolapse, I avoid, whenever it is possible, amputation of the cervix, as I desire to have that projecting portion of the uterus riding well back of the reconstructed perineum to aid in preventing the uterus paralleling the vagina.

THE ANATOMY AND SURGICAL UTILITY OF SACRO-UTERINE LIGAMENTS *

GEORGE B. SOMERS, M.D.
AND
F. E. BLAISDELL, M.D.
SAN FRANCISCO, CAL.

The sacro-uterine ligaments, from an operative standpoint, attract very little attention. While they have been the object of occasional study, neither their limitations nor their extensions have been fixed so as to give them a definite place in surgery. The general impression seems to be that they are difficult of access and both structurally and mechanically of doubtful surgical utility.

HISTORY

From 1902 to 1906, Bovée[1] published a series of articles calling attention to the sacro-uterine ligaments.

---

* Read in the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

[1] Bovée: Am. Gynec., July, 1902.

His bibliography shows that as far back as 1850 efforts were made to utilize the ligament in the treatment of retroversion of the uterus. In 1902 he gave an interesting historical account and described the various methods proposed for shortening the ligaments. The technic of these operations, whether the mode of approach was through the vagina or through the abdomen, consisted of folding or doubling the ligaments without actually isolating them. Bovée, however, exposed them by making an anteroposterior incision in the vault of the vagina and dissecting them out. He doubled each on itself and sewed the loop thus formed to the cervix below the normal point of insertion of the ligaments. The incision in the vagina originaly made longitudinally was then sewed transversely, which procedure assists in raising the cervix.

In appropriate cases, this is an easy and effective operation. While Bovée's articles attracted considerable attention at the time they were published, the profession has shown no sustained interest in the ligaments as surgical possibilities. The reason is probably because their mechanical importance is not generally understood. Furthermore, none of the operations proposed has appealed to surgeons as clear and mechanically sound methods of utilizing them.

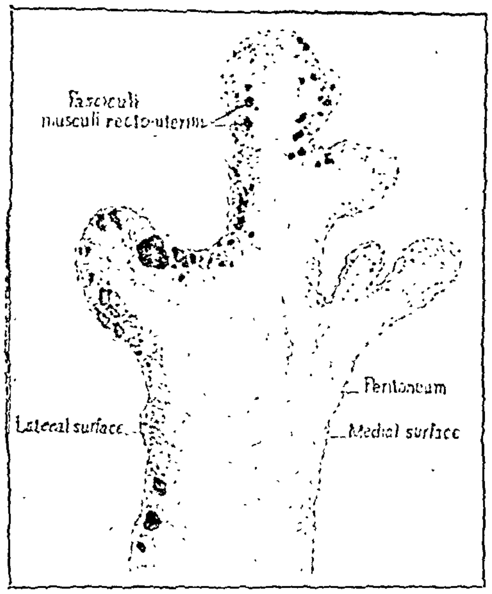

Fig. 1.—Transverse section of rectovaginal fold of Belgian hare.

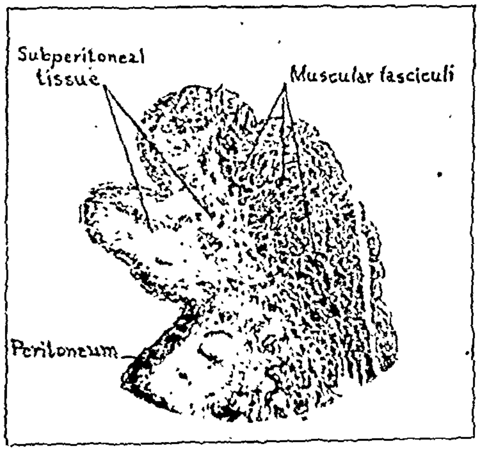

Fig. 2.—Transverse section through right recto-uterine fold in anterior part of middle third of child of 10 years.

In August, 1911, Jellette[2] of Dublin described a new operation for shortening the sacro-uterine ligaments. This article, to my mind, establishes their surgical value, for it demonstrates an easy and practical method of exposing, isolating and utilizing them as mechanical supports. With this advanced step in perfecting the technic of operating, I believe that shortening them should be accepted as one of the standard methods of treating retroversion and prolapse.

In order to judge whether or not utilization of these ligaments for this purpose is practicable, it is natural to turn to a consideration of their structure, relations and functions.

At my suggestion and for the purposes of this paper, Professor Blaisdell of the Division of Anatomy of Stanford University has made a special study of these structures. Although originally only a brief survey was planned, so many interesting problems were uncovered that his work has grown to monographic proportions and will be published later. The chief practical points of these observations will be given below.

A comparison of authorities leaves one in doubt as to what really constitutes the sacro-uterine ligaments. There are three structures involved—muscle, fibro-elastic tissue and peritoneal folds. So intimately related are they that authorities differ as to which should be included and which excluded from the true ligaments. The present study was taken up chiefly to arrive at a clearer understanding of the relations and functions of these tissues.

COMPARATIVE ANATOMY

Considerable light is thrown on the ligaments by observing their analogues and homologues in the lower animals. Here they appear in their simplest forms and one is able to follow the changes from the simple to the more complex. This fact led to the study of a comparative series of animals consisting of guinea-pig, Belgian hare (Fig. 1), cat, dog, and monkey. In this series the parametrial tissue, ligaments and folds were cut in serial sections and subjected to careful histologic analysis.

While each specimen in the series presented interesting differences, the general structure of the tissues under observation was practically the same in all. The condition found in the cat affords a fair example of the series examined.

In animals which habitually assume the horizontal position the uterus is either double or bicornate. It is long and slender and its weight is distributed along an extensive peritoneal attachment, often as far forward as the kidney. This arrangement requires only slight support from the peritoneal folds. There is no need of true or fibrous ligaments. The folds of peritoneum acting as ligaments are very thin and transparent and any fibrous or muscle tissues that may be found in them are only rudimentary structures.

If the bicornate uterus of the cat be pulled ventrad so as to expose the pouch of Douglas, two well-marked folds of peritoneum are seen, in the situation corresponding to the sacro-uterine ligaments. They run on either side of the pouch of Douglas ventrad dorsad, but it will be noticed that the folds are not sacro-uterine, but rectovaginal, inasmuch as they run only from rectum to vagina instead of from sacrum to uterus. In none of the lower animals does this ligament show any disposition to connect sacrum and uterus.

MICROSCOPIC STRUCTURE

A transverse section of one of these folds shows under the microscope an interesting condition. In all the animals examined the peritoneum forming the fold was much thicker than the surrounding peritoneum. This hypertrophy was confined chiefly to the fibrous layer or stratum fibrosum. Within this fibrous layer, and therefore distinctly within the peritoneal structure, were found a number of small fasciculi of unstriped muscle fibers. They originate from the uterus, pass first to the fold attached to the vagina and remaining within the fibrous layer of the peritoneum pass backward toward the rectum.

The observation of muscle fibers within the structure of the peritoneum itself is thought by Blaisdell to be new. The muscle fibers found in the ligament are usually described as lying between the layers of the peritoneal fold and are called the recto-uterine muscle, but, as will be shown later, these fibers constitute a separate structure with a well-marked levator function. It is accordingly suggested that they be called the levator uteri muscle to distinguish them from the true recto-uterine muscle.

---

[2] Jellette: Surg., Gynec. and Obstet., xiii, No. 2.

The muscle fibers situated within the structure of the peritoneum constitute the true recto-uterine muscles. They are found not only in animals but also in the human female. The thickened musculofibrous structure forming the rectovaginal folds in the lower animals are primitive and the sacro-uterine folds in women are the same in histologic structure and function.

In the lower animals, the space between the peritoneal layers of a fold contains principally areolar tissue. The muscle fasciculi and fibro-elastic tissue so abundant in the human female are absent or only rudimentary.

Monkey.—Emphasis is laid on the thin, transparent nature of the peritoneal folds in the lower animals and the small amount of weight supported by them. With the assumption of the upright position, the uterus and its appendages sink down into the pelvic cavity and contract into a solid mass. With increased concentrated weight, there is demand for firmer support and we find, coincidently, the development of abundant fibro-elastic and muscle tissue within the folds. In the monkey, for instance, the uterus is undivided and the anatomic conditions are similar to those in women. Here, with the sinking down of the uterus, we find the rectovaginal fold changes to a sacro-uterine and in other respects the structures are human in character, but to a less marked degree.

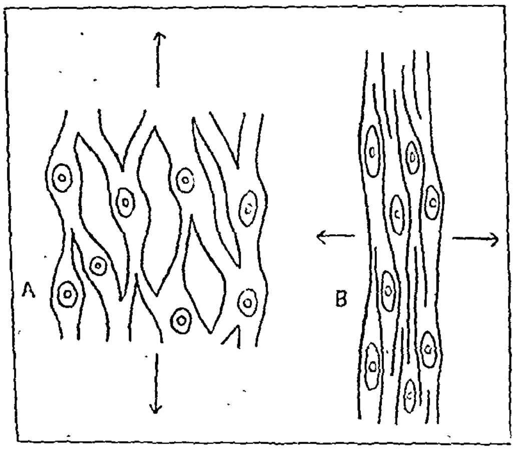

Fig. 3.—Fibro elastic meshwork which forms (a) potential, (b) temporary sacro-uterine ligament.

Woman.—In examining the sacro-uterine ligament in the human female we find that it is much thicker, stronger and more prominent than its homologue in the lower animals. A cross-section shows it to be composed of three main structures: (1) a thickened peritoneum, (2) a fibro-elastic meshwork, and (3) muscle fasciculi. These component parts will be considered separately.

PERITONEAL FOLDS

In the lower animals, the peritoneal structure alone is prominent. The muscle fasciculi and fibro-elastic tissues are only rudimentary. In woman the folds which cover the sacro-uterine ligaments vary considerably in prominence. Sometimes they are only potentially present and appear only when traction forward is made on the uterus. At other times, they may be traced by the eye throughout their course.

Posteriorly, the folds vary in their attachment, sometimes being connected with the rectum and sometimes with the sacrum. Whether the fold becomes recto-uterine or sacro-uterine depends on variation in the position, size and attachment of the rectum. If the rectum is large both folds may be recto-uterine. If the rectum is small, and especially if it has a mesentery, the folds will be sacro-uterine. If the rectum is located to one side, the adjacent fold may be recto-uterine and the opposite sacro-uterine.

Another marked feature of the peritoneum is that traction forward on each sacro-uterine fold usually raises the surface into a series of ridges. The meaning of this is that the peritoneum has a direct attachment to the fibers beneath. This attachment was demonstrated by microscopic examination and the fibers of the underlying meshwork traced to the fibrous stratum of the peritoneum. This connection adds considerably to the strength of the true sacro-uterine ligament.

FIBRO-ELASTIC MESHWORK

Beneath the plicae sacro-uterinae, and filling all that space about the uterus called the parametrium, there is found a dense fibro-elastic meshwork. This tissue consists of interlacing fibers ensheathing the vessels and nerves. Careful dissection shows that it is attached to the fascia of the levator ani below, the obturator fascia laterally and the peritoneum above. The general course of these fibers is from the cervix toward the presacral fascia, spreading out to the various points of attachment. It will be remembered that this tissue, while abundant in the human female, is practically absent in the lower animals. Its appearance is coincident with the assumption of the upright position and its function is both to protect and to support. In fact, it may be called the fibro-elastic suspensorium of the uterus.

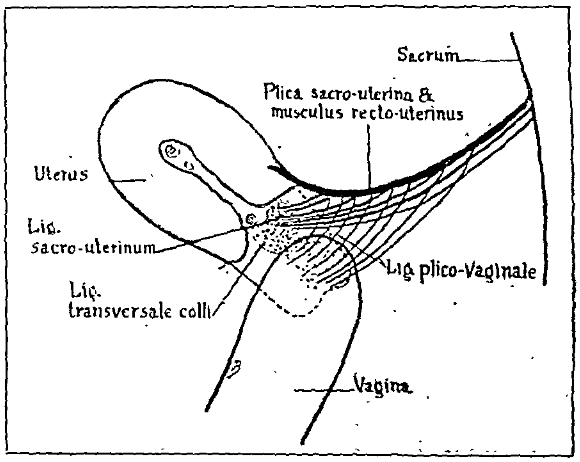

Fig. 4.—Diagram showing origin and attachments of sacro-uterine ligament.

In a state of rest, the fibro-elastic tissue remains a diffuse network. When traction is made in any direction, condensation occurs along the line of traction and the fibers are thrown into a bundle forming an elastic cord. Remove the traction and by virtue of inherent elasticity or resiliency the tissue resumes its meshwork character. The sacro-uterine ligament is formed from the meshwork by traction in this manner.

MUSCLE FIBERS

The fibro-elastic meshwork about the uterus is interlaced with numerous fasciculi of smooth muscles. These are more abundant close to the uterus than in the more distinct parts, inasmuch as they originate from the uterus. They are the cause of the dense or cord-like character of the *sacro-uterine* ligaments and also of the so-called cardinal ligaments which pass off from the sides of the uterus at the base of the broad ligaments.

These fibers by contraction and by pulling on their attachments to the fibro-elastic meshwork have the power of raising the uterus. They evidently act in response to reflex stimuli. Inasmuch as these muscle fasciculi form a separate structure with a distinct function it is suggested by Blaisdell that it be called the levator uteri muscle.

PLICOVAGINAL LIGAMENT

In studying the course of the fibro-elastic meshwork within the peritoneal folds, it was demonstrated that a distinct mass of fibers ran from the anterior two-thirds of the sacro-uterine fold (plica sacro-uterina) down to the vault of the vagina. The function of these fibers is clearly to sustain the vault-like character of the lateral and posterior fornices.

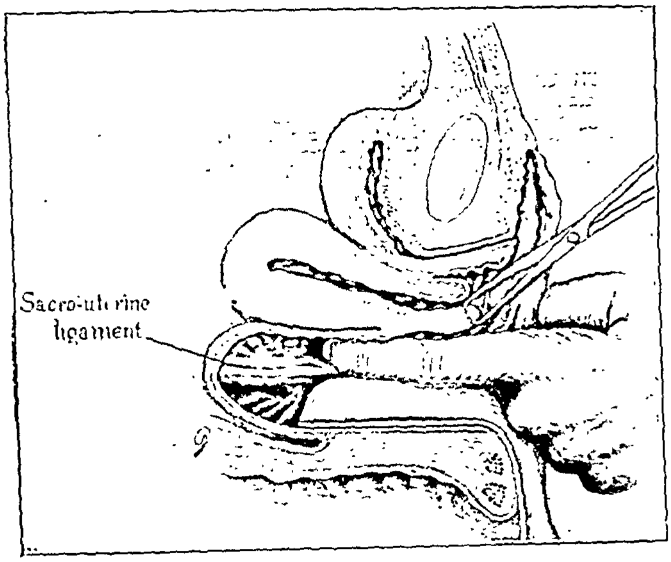

Fig. 5.—Palpation of ligament.

As they are ligamentary in function and have distinct points of origin and insertion it is suggested that the structure be called the plicovaginal ligament.

SACRO-UTERINE LIGAMENT

The true sacro-uterine ligament is quite distinct from the peritoneal folds and from the muscle fibers found between the folds. It is formed from the diffuse fibro-elastic meshwork. It differs much from our ordinary conception of a ligament inasmuch as it is not a permanent cord, but only potentially so. In function the ligament is inseparably connected with the peritoneal folds and the muscle fasciculi. Acting together the three structures have both a supporting and an elevator function.

The thickened musculo-fibrous character of the peritoneal folds renders them chiefly supporting.

The fibro-elastic meshwork through its inherent elasticity and resiliency restores the uterus and vaginal vault to their normal position when pushed or pressed down.

The bundles of muscle fibers forming what has been called the levator uteri, by their contractility, raise the uterus in response to reflex stimuli.

It is hardly necessary to compare the supporting value of the sacro-uterine ligaments with that of other uterine ligaments. Their importance is indicated by their structure and conceded by most authorities. Bovée insisted on their value in this direction and Goffe[3] has made the statement that the sacro-uterine ligaments are the most *rational structures we can use for restoring the uterus to its normal position.* The truth of this remark is readily revealed when we attempt to answer the question, What will support the vaginal vault if the sacro-uterine ligaments fail?

SURGICAL UTILITY

Granting the supporting value of these ligaments, it becomes surgically important to determine whether they may be utilized practically, as, for instance, in restoring the prolapsed uterus and vagina. The surgical utility of these structures depends on (1) their accessibility, (2) on whether their ligamentary character is definite enough to allow of shortening and (3) whether shortening is mechanically effective.

Accessibility.—In relaxed vaginal outlet and in severe cases of prolapse the ligaments are easily reached. If the cervix be drawn down with a volsellum, the cord-like ligaments, may be easily felt with the examining finger. They may be outlined and their size relations and point of insertion into the cervix determined. The simplest method of exposing them after they have been located is to make a circular incision about the cervix as proposed by Jellette and dissect back the cuff of mucosa until the insertions may be plainly seen. They may then be isolated by blunt dissection, and even cut away from the uterus if deemed necessary. In cases of prolapse, I have been in the habit of exposing them by removing a small triangular flap posterior to the cervix. This procedure not only gives access to the ligaments but at the same time allows for transposition of the cervix to a higher position.

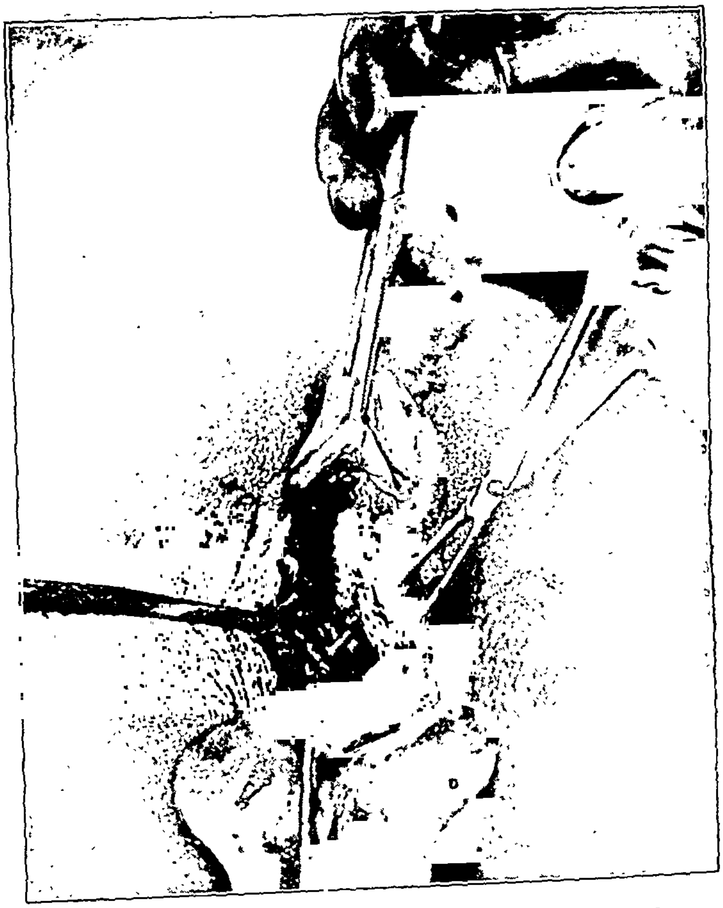

Fig. 6.—Sacro-uterine ligament exposed and isolated.

Ligamentary Character.—After exposure they may be isolated by pushing a clamp beneath them. By further dissection they may be completely separated from the uterus. They appear to the eye like loose bundles of muscle fibers forming a cord of considerable size and length, which may be manipuated as a ligament.

---

[3] Goffe: The Journal A. M. A., July 5, 1902, p. 16.

MECHANICAL UTILITY

After exposing the ligaments a few tests will show that they may be doubled on themselves as proposed by Bovée; sewed to each other as proposed by Byford or separated from their attachments and sewed to a new position as proposed by Jellette. Shortening is attained by any of these methods and the practical result of lifting the cervix follows as a matter of course.

The strength of the ligament is sufficiently attested by its size and resistance to tension. When it is remembered that the fibro-elastic meshwork from which the ligament is derived has a very broad attachment to surrounding fascia, and especially an insertion into the musculofibrous layer of the peritoneal fold, its ability to hold up the cervix becomes self-evident.

CONCLUSION

In conclusion, the object of the above study has been to arrive at a clearer understanding of the anatomy and surgical value of the sacro-uterine ligaments. I have had the opportunity of operating on these ligaments ten or twelve times, and as a result of both study and experience feel (1) that they are worthy of more general attention; (2) that the operation of shortening them is both practicable and successful, and (3) that it is particularly indicated when retroversion or prolapse is accompanied by relaxed vaginal vault.

Lane Hospital—1520 Lake Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. MARTIN, MONTGOMERY AND SOMERS

Dr. A. E. Benjamin, Minneapolis: This subject is a very important one. Operators have different points of view. One man has corrected this prolapse by the vaginal route, another by the abdominal. It is for the purpose of crystallizing our ideas and coming to some definite understanding regarding the proper position of the uterus and the underlying factors that we discuss the matter fully. I think most of us should study anatomy more thoroughly and especially the anatomy of the female pelvis, if we are to understand why we have prolapse and do this work properly. What is the mechanism and what are the factors necessary for the proper position of the uterus, and why do we have prolapse or misplacement of this organ? When we arrive at a thorough understanding of this subject our opinions will differ but little. I agree with what Dr. Martin has said in regard to prolapse in women past the menopause. The Watkins-Wertheim operation is satisfactory and I have had more women return to me expressing their gratitude for the results of this operation than for those of any other perhaps. It seems to be founded on the right principle, taking into consideration the anatomic structures and elevating the rectum which is prolapsed and in which we have a rectocele. It elevates the prolapsed bladder and does not interfere with its function. There is not the pain and discomfort so often encountered if the bladder is not properly replaced. Dr. Martin's idea of fastening the fundus a little higher up on the bladder and the use of the uterovesical ligaments is one we should all recognize, so that our patients who have not passed the menopause may have the benefit of this method. It has been most difficult to get a uterus to stay in place after prolapse in women past the menopause and especially when the tissues have atrophied. One feature which we must consider is the intra-abdominal pressure. Very few of these uteri will prolapse if there is not a force above pushing them down.

Dr. William M. Polk, New York: The difficulty in dealing with the questions that have been presented grows out of the fact that we have so many admirable operations devised for this troublesome condition. Is this a hernia? If so, how does it compare with other hernias, and which is the best way of meeting the difficulty? There are certain general principles that we all recognize as accepted in all cases of hernia. First among these is the principle that the peritoneal support shall be of the first order. Unless we take care of the sac, no matter how skilfully the operation is performed, it is worthless. The weak point in the pelvis is the region of the bladder; the strong part, the region of the sacrum. If we can overcome the tendency to weakness in the bladder region, we can solve the question of prolapse. In spite of the variety of methods, however, there is ample room for all, because the varieties of procidence are almost infinite. Not only are each and all subject to different methods of procedure, but the condition of the patient also must always exercise a potent influence on the measure it is proposed to adopt. A woman of 60 whose tissues have undergone fatty degeneration is not in condition to make good an operation applicable to a woman of 30. There are conditions of congenital defects in these muscles which make certain procedures difficult in certain women. In certain women no changes have taken place in the levator ani muscles that make it a difficult matter to build the support from below. In others, especially the obese, the structures to which surgical skill is applicable are from the outset defective. There is no doubt, therefore, that in these various conditions presented to us we shall find the appropriate operation among those suggested. The beginnings of prolapse are always easy to correct. Operators should bear in mind that not only is it essential to have support from below, but that it is also of the highest importance that there is resistance from above. It must be understood also that the region of defect is to the front of the uterus rather than behind it. While every effort should be made to strengthen the support of the uterus, notably the use of the sacro-uterine ligaments, without adequate attention to the anterior supports of the uterus all measures will be in vain. Therefore, the anatomic and pathologic problem to be faced is this, that when prolapse begins, it begins from below posteriorly by lessening of the support there, but that in a short time the prolapse is increased by the insufficiency of the support above. Every measure should be resorted to that will shorten and make shallow the peritoneal surface that lies between the uterus on the one hand and the symphysis pubis on the other. There are a number of these procedures.

Dr. Walter B. Dorsett, St. Louis: We must consider the subject from the point of view of physiology as well as from that of pathology. We have to judge as to what constitute the natural and normal supports of the uterus. In my opinion each has its special function to perform. Aside from the different ligaments that support the uterus, we must not lose sight of one of the most important factors in the natural position of the uterus, and that is the intra-abdominal pressure. The intra-abdominal pressure on the uterus is on the posterior wall when it is in its normal position and on its anterior wall when it is retroverted. The deviation from the normal allows the uterus to sag down and feed itself, as it were, into the vagina. The uterine sacral ligaments are, so far as I have been able to observe by section and by digital examination, unimportant factors in the support of the uterus, and we must study them from a physiologic and from a pathologic standpoint. Dr. James N. West discussed this question in 1904. He proved experimentally that the uterosacral ligament does not enter forcibly into the consideration of the support of the uterus.

I wish to call attention to the different actions of tissues composing ligaments and those composed chiefly of muscle in the cadaver when subjected to strain. In cases of retroflexion with congestion of the body of the uterus, the uterosacral ligaments hold the uterus in a retroflexed condition, and I dare say that all of us, in examining these cases, when we have passed the two fingers into the posterior vaginal fornix and made pressure, have felt it slide up beyond these ligaments and out of our reach. I believe that in these cases of retroflexion, the uterosacral ligament holds the uterus in a retroflexed position, but I do not believe that it has an important rôle to play in holding it in position, because of the fact that peritoneal tissue and very little muscle tissue hold it in place. I have never done the operation. I do not believe that it is a good operation, however, for the reason that it is done through the vagina. If such a condition could be brought about through the abdominal wall by making a folding of the round ligament on itself, if it had sufficient muscle tissue to hold it there, I believe that the operation would be a good one.

Dr. J. Riddle Goffe, New York: I have utilized the uterosacral ligaments for many years and I am a firm believer in their utility. Dr. West, in describing his experiment by which the uterine ligaments were put on the stretch, said that the uterosacrals were the first to show tension. That is evidence of their relative importance in maintaining uterine equilibrium and of the very slight support needed by the uterus when in the normal position. Only when retroverted can we need the firmer and stronger ligaments. The uterosacral ligaments are all-sufficient when the uterus is in normal position.

In the operations described this morning the entire stress was laid on the anatomy and the pathology discovered. The physiologic functions were entirely ignored. The doctors speak of putting a plug in the hernial hole, of building up a bottom to prevent things from coming out, and Dr. Montgomery even speaks of the interposition of muscles. I should not consider the interposition of muscles for closing this space. I should restore those muscles to their normal position so that they can perform their normal function, which is to lift the anus in defecation and deflect intra-abdominal or pelvic pressure. They are not plugs or dead tissues; they are vital energizing tissues and we should look to their function and then restore it, and not the anatomy only.

must disagree with Dr. Polk in his assertion that the weak spot is in front. In the great majority of these cases the uterus comes down first, then the rectum and finally the bladder. The support in front is, as a rule, the last to yield. Therefore, in all these operations, if the woman is in the child-bearing period, we must first restore the uterus to its normal position, then look after the bladder and lastly the rectum.

There has been no reliable principle up to a very recent date on which these operations can be based. Drs. Benjamin and Dorsett have struck the keynote in referring to the intra-abdominal pressure. It is the direction and control of the intra-abdominal pressure that determines whether or not the uterus will stay in place. The intra-abdominal pressure when it impinges on the uterus forces it down until the ligaments are taut. The cervix gives way and allows the uterus to tilt up sufficiently to deflect the pressure into the pelvic outlet.

The thing we want to look to is the proper restoration of the uterus to the normal position in child-bearing women by restoring its ligaments so that it can meet and control intra-abdominal pressure when it comes down in the pelvis. I have an operation that is applicable to child-bearing women, and that is modified to meet conditions that come later in life. In child-bearing women I restore the uterus to the normal position, shorten the ligaments to permit it to meet the abdominal pressure efficiently, and then stitch up the bladder so that it will be suspended from above.

In elderly women, at the menopause or later, I remove the uterus, but restore a deflecting plane made up of the broad ligaments to control and direct the intra-abdominal pressure. That is the entire principle and explains why it is that the uterus is retained in place so easily when in its normal position and why, when it is not, we have these disastrous consequences.

Dr. Robert Earl, St. Paul: The crucial point in the consideration of the various operations for prolapse of the uterus is whether or not the uterus is suspended or supported. What maintains the uterus in position? The peritoneum, blood-vessels, ligaments, pelvic-floor muscles, pelvic fascia, fat and skin must be considered. That the peritoneum cannot hold the uterus in position is evidenced by the fact that hernia occurs if there is a constant fight between intra-abdominal pressure and the peritoneum. That the blood-vessels and nerves cannot hold the uterus in position is evidenced by the fact that there is a marked elongation of the blood-vessels and nerves in cases of floating kidney or other loose abdominal organs. The round ligaments never hold the uterus in position because they are curved. You can place a forceps on the cervix and pull the uterus down and out and the round ligaments will not become tense or straight. The uterosacral ligaments do, in a considerable measure, help to maintain the uterus in position by suspension; but, the uterosacral, like the round ligaments, are made up of muscle tissue of the uterine type and one of their functions is to hold the uterus down, aided by abdominal pressure, during the pains of labor. One of the functions of the round ligaments is to hold the body of the uterus forward, and the function of the uterosacral is to hold the cervix back, thereby maintaining the uterus on a horizontal plane in order that the abdominal pressure shall strike the uterus on its broad, flat surface, forcing it against the vaginal walls and forcing all against the most resistent part of the perineum. The broad ligaments being composed of peritoneum, connective tissue and blood-vessels all stretch. The levator ani muscle is practically an abdominal-wall muscle. It contracts synchronously with the other abdominal-wall muscles. Were it no so, we should have bulging of the perineum during inspiration. In spina bifida and injury of the fourth sacral nerve, prolapse of the pelvic organs occurs in the female and a bulging of the perineum in the male. This I believe is conclusive proof that the pelvic organs are supported by the muscular perineum and are not suspended by the ligaments.

There are many operations recommended, but each operator concludes by saying that the operation must be completed by building up the perineum. I believe that that is the secret of success in all of these operations—the building up of a good muscular perineum. When the perineum is relaxed it is because of laceration, atrophy, dilatation or weakness of the muscular tissue. Then the intra-abdominal pressure forces the pelvic organs gradually out; therefore the weakened pelvic floor is the main cause of prolapse. In those cases in which it is not possible to build up a good muscular perineum, either the uterus or stump of the cervix must be anchored securely to the anterior wall of the abdomen or there will be a considerable percentage of failures.

Dr. A. Goldspohn, Chicago: In the Wertheim-Schauta-Watkins operation the uterine cavity becomes wholly inaccessible. This is serious. We know that senile endometritis is frequent enough in women who have not a sufficiently distorted position of the uterus to invite it. I should abhor creating that condition in the pelvis of a woman even if she could not conceive. I think that it would be better to remove the uterus, although that is not the best way of curing the prolapse. We can utilize that old uterus in curing the prolapse and simplify the operation in these decrepit women by not removing it. I am glad to hear emphasis laid on the proper reconstruction of a foundation from below by getting together the lateral halves of the levator ani muscle and the deep pelvic fascia in a firm union in the median line by transversely placed sutures, not one inch from the vulva as Dr. Martin suggests, but two inches. It cannot be done with less than that. It was my privilege fourteen years ago, to introduce the procedure known as "intrapelvic, intravaginal perineorrhaphy without loss of tissue." I am sorry that I have neglected to say much about it since that time.

If you will make an actual restoration of the pelvic floor, the morbid conversion of things that Wertheim proposed is not necessary. It will be sufficient simply to detach the bladder from the front of the uterus and hang the uterus in a perpendicular position, not horizontally, simply turn it forward half as far, a quarter instead of a half of the circle. Then place the bladder, the mischief-maker, where it cannot do harm, that is, on top of the fundus of the uterus, and anchor the uterus firmly to the anterior vaginal wall. Then build up the right kind of foundation from beneath. In some extreme cases of old women, in whom the parts have become extremely relaxed, atrophy is an important factor. It is better in these cases to make a ventral incision and anchor the fundus of the uterus to the abdominal wall by a Gilliam operation well drawn up, plus ventrofixation by a fibrofibrous union. This gives a union that will never let go. Then you must do a real restoration of the pelvic floor.

The operation to be discussed is not prolapse of the uterus in women who are no longer to bear children, that I regard as practically accomplished. The question before the profession is to find an operation that will be curative in young women who are yet to bear children; that class of women we have few of in this country, but many abroad. The efforts of Dr. Martin in that direction are commendable; but I would call attention to the fact that his suggestion of drawing the sacro-uterine ligaments from behind and uniting them in front of the cervix is an operation of a man in Dublin, published about two years ago. The anatomic study of Dr. Somers calling our attention to the importance and great utility of the uterosacral ligaments is exceedingly commendable.

Dr. George Gellhorn, St. Louis: The multiplicity of conditions encountered makes it imperative that we familiarize ourselves with a number of operative procedures. It is obvious that an operation which is indicated in a woman at or near the menopause cannot be applicable during the child-bearing period; nor can a method by which a uterus may be saved be equally suited to cases in which the uterus must be removed, for instance, in fibroids What becomes of our boastful principle of individualization in medicine if we operate on every patient by the one method that we happen to know best, or by chance have originated ourselves? The Wertheim-Schauta-Watkins operation is excellent in certain well-defined cases, but totally unsuited for women in the child-bearing age. For these the Vineberg method will be found to have many attractive features. The Goffe and Polk methods and a dozen others are available and advisable in certain cases, but none of them is complete without a solid perineorrhaphy.

Dr. G. Betton Massey, Philadelphia: I believe that if surgeons will refer their patients after operation, and possibly some of the younger women before operation, to adequate treatment of muscle-exercising character, they will get far better results. They are not dealing with a fibrous skeleton alone, but with muscular tissue. We have come back to the belief in the importance of support from below. Muscular tissue is above, in the abdominal wall, as well as below. We should restore the abdominal tone, and that can be done effectively by powerful galvanic currents turned on and off rhythmically. A more recent current for that purpose is known as the sinusoidal current, having to a great extent the characteristics of the old galvanic current and of the faradic current. Either of these currents is particularly applicable to younger women. I think all will usually fail in older women. I urge it after operation and before operation. It should be done, however, by a man who understands its application, and it should be continued for an adequate length of time, which is not less than three months.

Dr. E. E. Montgomery, Philadelphia: I endeavored to leave the impression that the operation which I suggested was limited in its application to a certain class of cases. I do not wish to be understood as advocating the removal of the uterus in every case of prolapse. That has been mentioned by the men who have discussed this subject. It is important that we consider the various conditions which maintain the uterus in its proper position. This is not the peritoneum alone, nor the muscular structure. It is a combination of all the structures working together that serves to keep the organ in its proper position. It is impossible after an extensive prolapsus to restore these structures to their normal relation. We are obliged to bring them together and place them out of the ordinary relation and situation in order to accomplish restoration and prevent hernia. In this displacement there is, as mentioned by Dr. Polk, a weakened position, generally in front, which permits sliding down of the bladder; the uterus may push down in the center. There is also a weak point between the levator ani muscles and the rectum. We see through this prolapse of the rectum in women who have not given birth to children. It is simply a diastasis of the levator ani muscles which permits the rectum to come down between them. If this has continued for a length of time the rectum becomes adherent to edges of the muscles. The levator ani muscles can be brought together in front to form a wall to prevent protrusion of the rectum. It is important, as mentioned by Dr. Earl and Dr. Goldspohn, that this operation should be carried high on this muscle so that the muscle wall shall be brought together in front of the rectum for some distance. I have seen cases in which after operation hernia recurred; the intestine and peritoneum pushing down caused stretching and atrophy of the structures below, requiring subsequent operation. The uterus can be retained in position by folding together the structures. Dr. Polk was modest in not having mentioned an operation of his own device, that of dissecting down between the bladder and uterus in front, folding together the structures so as to hold up the uterus, then shortening the broad ligaments posteriorly, bringing the uterosacral ligaments over them in such a way as to maintain the uterus at a higher level. I wish also to commend the operation described by Dr. Somers as being an exceedingly valuable addition to the subject of displacements of the uterus.

Dr. George B. Somers, Omaha: My interest in the sacro-uterine ligaments is directly connected with my interest in the problem of curing prolapse. It is quite apparent from the papers and discussions presented to-day that men who have attempted to devise operations solving the problems of prolapse have divided themselves into two camps, and in their operation of choice one camp advocates the removal of the uterus, the other its preservation. The two principal papers to-day illustrated this. One author advocates the Wertheim-Schauta-Watkins operation; the other, an operation that I think we may safely attribute to Dr. Goffe, namely the removal of the uterus and the uniting of the round and the broad ligaments together as a support below. There would be no quarrel at all on this subject if it were not for the operation of choice. If anybody says that the removal of the uterus is the operation of choice, then at once the conservative camp rises in arms. On the other hand, those who advocate removal will say that the preservation of the uterus is not a surgically attractive procedure. When we can agree that one operation is good in one case, and that the other operation is good in another, then the problem is settled. I think that Dr. Montgomery in prefering hysterectomy saved himself from completely going over to the enemy by saying that he did not advocate removal in all cases. When it is necessary to remove the uterus, then the operation described by Dr. Montgomery is the best operation that can be performed. When a cystocele complicates prolapse, the anterior vaginal wall must be supported. There are two ways of doing this: (1) by placing the uterus beneath the bladder or (2) by removing the uterus and bringing the round ligaments underneath. My preference is for the former for conservative reasons.

Returning to the sacro-uterine ligaments, my attention was directed to them by the fact that in the operation of vaginofixation we frequently find that the uterus will assume a flexed position after the operation is completed, because the cervix is left without support. The only remedy for this that I can see is the use of the sacro-uterine ligaments, shortening them so as to lift up the vaginal vault.

Sneeze Powders.—Charles H. LaWall, in a paper on "Chemistry and Practical Jokes" (*Pennsylvania Pharm. Assn. Proc.*, 1913, p. 221), describes the composition of sneeze powders as follows:

> "It is a different matter, however, in the case of the sneeze powders, as they are called, which are sold in tiny vials labeled 'Kachoo Powder,' each containing about 10 grains of a gray powder which I found to be one of the most acrid and irritating substances known to chemistry. Contrary to the usual supposition, red pepper, hellebore, bayberry, sanguinaria, tobacco or other common sternutatories, are not present in this material, which I have recently investigated and found to consist almost entirely of acridin, probably a crude form of the substance.
>
> "Acridin, $C_{13}H_9N$, is a basic substance obtained as a fraction of coal-tar, associated with crude anthracene. Its name is indicative of its properties. It is a powerful sternutatory and skin irritant. The only legitimate use to which it has ever been put is as an insecticide and also in compositions for coating the bottoms of vessels to preserve them. It is said by some authorities that the preservative properties of some coal-tar products are due to the presence of small amounts of acridin."

STUDIES IN AUSCULTATORY BLOOD-PRESSURE PHENOMENA

THE CLINICAL DETERMINATION OF DIASTOLIC PRESSURE *

LOUIS M. WARFIELD, M.D.
MILWAUKEE, WIS.

A mass of data concerning the value of systolic pressure readings has accumulated within the past few years. Hypertension has become a word which is in danger of being worshipped as a fetish. It seems to me that much of the hypertension which we see is a *compensatory* effort on the part of the heart to maintain the circulation in equilibrium. Regarded in this light it becomes physiologic, and successful attempts to reduce it not infrequently produce unpleasant results.

To the other phenomena of the blood-pressure, the diastolic pressure and the difference between the systolic and diastolic pressures—the pulse-pressure—*but little* attention has been paid. Possibly this has been due to the fact that the methods of measuring the diastolic pressure have not been uniform, and thus no comparison was possible between the results of observers, and the results of any one observer were so *variable that* no conclusions could be drawn. It is my purpose to call attention to a reliable and uniform method of determining the point at which diastolic pressure should be taken.

It will, I think, be granted now that the auscultatory method of measuring blood-pressure is the most satisfactory and uniformly accurate of all the methods practicable for bedside work. Further, that the systolic pressure is to be read at the moment when, with a gradually decreasing pressure in the arm cuff, a clear clicking tone can be heard. The diastolic pressure has received but *scant study*. This has no doubt largely been due to the fact that there were various more or less inaccurate methods in use, and no method which gave results comparable to those which could be obtained for systolic pressure.

Fig. 1.—Fast drum. Sudden decrease in size of pulse-wave at 4, marking the change from clear sharp tone to dull tone.

Although Korotkoff[1] in his original communication called attention to the fact that the diastolic pressure should be taken at "the end tone," that is, at the point at which the clear third tone was suddenly replaced by a dull tone, and Fischer,[2] and Lang and Manswetona[3] confirmed this, Ettinger,[4] on the basis of a large series of observations, made his five tone phases and held that the diastolic should be read at the disappearance of all sound. Gittings,[5] and Goodman and Howell[6] in their observations evidently took Ettinger's word and used the disappearance of all sound as the place to measure diastolic pressure. Goodman and Howell[6] went so far as to divide off the phases between first and fifth into a series of four tone phases and, calculating the percentage of every tone phase to the pulse-pressure, they attempted to *show that the* sum of the percentages between first and second and fourth and fifth should be less than the sum of second to third and third to fourth. That their attempts to measure heart strength by this means is inaccurate will be demonstrated later in this paper. They did call attention, however, to the fact that one could note irregularities in the strength of the individual heart beats more accurately with the auscultatory method than by listening directly over the heart. They called these audible irregularities, *tonal arhythmias.*

It will not be granted that after one has taken the systolic pressure he has completed the blood-pressure determination. It seems logical to believe that the pulse-pressure, the actual head of pressure driving the blood into the peripheral vessels, and representing the systolic output of the heart, should be most important in cardiac prognosis. We cannot determine *the pulse*-pressure unless we have measured the diastolic pressure. It is *not so much* the knowledge of the pressure under which an organ receives its blood, as *it* is the knowledge of the amount of blood an organ receives per unit of time, that enables us to judge of functional capacity. *It* would be important to be able to calculate the *velocity of the blood. Within limits*, but within very small limits, there is a relationship between pulse-pressure and velocity. Within these limits, theoretical as well as experimental, the velocity of flow is equal to the pulse-pressure times the pulse-rate. Unfortunately this simple formula is dependent on so many disturbing factors in the circulation that it is not possible to use it in but a *limited number of cases*. In normal persons after exercise this formula apparently holds good; but in the high pulse-pressures of chronic nephritis, *for example, it* is most inaccurate, for we have no means of measuring the mass movement of the blood. In general, I think, it *may* be said *that a diminution of* the pulse-pressure means lessened velocity of blood-flow, but the reverse does not hold good. Without going further into the value of the pulse-pressure determination, which will be dealt with in Dr. Stone's paper, suffice it to say that there seems to be a very definite value, and therefore the determination of diastolic pressure assumes considerable *importance.*

In a paper[7] read before the Wisconsin State Medical Society in June, 1912, evidence was brought forward to show that the diastolic pressure should not be taken at the disappearance of all sound when using the auscultatory method. As has been said, this was the point used by many investigators. The conclusion arrived at from a study of records made with the Erlanger sphygmomanometer was that "the diastolic pressure is not usually at the point of disappearance of all sound—the fifth phase." This was a negative conclusion, but seemed to render invalid the work of those who took the fifth phase as the diastolic pressure.

Erlanger[8] showed some years ago that with his instrument the point at which diastolic pressure should be read was at the instant when the maximum oscillation of the lever suddenly became smaller. It was while checking up the graphic with the auscultatory method with Erlanger's instrument that it was noticed that the disappearance of all sound did not correspond with this sudden diminution of the oscillation of the lever connected with the brachial artery. The question seemed important enough to settle for future work, so that an attempt was made to show experimentally on dogs that the fifth phase was below diastolic pressure, and an effort was made to find out just what phase in the auscultatory phenomenon was the real measure of diastolic pressure. These experiments[9] were carried out in the physiologic laboratory of the University of Wisconsin. The conclusions reached from these experiments were that the diastolic pressure was not at the point corresponding to the disappearance of all sound, but at the change from clear to dull tone. This corresponded with the minimal pressure recorded by a Dawson maximum and minimum pressure recorder inserted in the dog's carotid pressure manometer system.

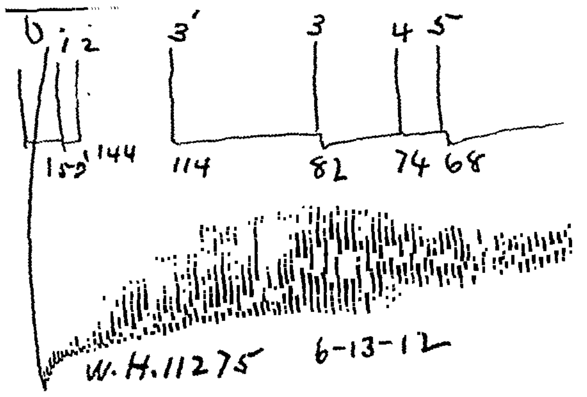

Fig. 2.—Slow drum. Sudden decrease in amplitude at 4.

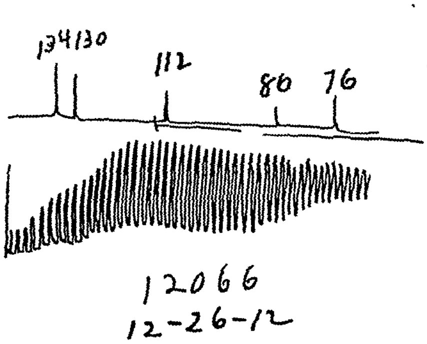

Fig. 3.—Sudden decrease near 86, fourth tone.

With this data clinical observations were resumed. It was found that with the exercise of greater care and precision rather sharp records were possible. It was seen that during the period of the third tone phase the oscillations of the lever on the drum reached a maximum and remained at approximately the same height for some millimeters while the pressure was gradually falling. At a point at which the third tone, clear and distinct, became dull, there was an appreciable decrease in the height of the pulse-wave (Figs. 1 and 2). From this point to the disappearance of all sound there was a gradual diminution of the size of the pulse-waves.

For normal pressures the difference between the fourth (dull) tone and the fifth (disappearance of all tone) phase, amounted to from 4 to 10 mm. Occasionally the difference was so little, the change from sharp third tone through fourth dull tone to disappearance of all sound was so abrupt, that one could take the disappearance of all sound as the diastolic pressure with an error of not more than from 2 to 4 mm. For high pressures the difference was never less than 8 mm., and was found as much as 16 mm.

Comparative readings were taken by watching the oscillations of the mercury column while recording the oscillations of the lever on the drum. It was found impossible to obtain readings comparable in accuracy to the auscultatory method, owing to the fact that the weight of the mercury column did not record changes as quickly as the lever attached to the air tambour. With the dial instrument, however, it was seen that the sudden lessened amplitude of the needle oscillations after the maximum was reached *corresponded accurately to* the point at which the third tone became dull. Hence with some practice one could use this point on the dial instrument as the place to read diastolic pressure. *It is better, simpler and, for most observers, more accurate to use the stethoscope and hear the change of sound.*

In normal persons it is a matter of no difficulty to determine accurately the diastolic pressure. In many cases of decompensation with intermittent and irregular hearts it is impossible to determine either the systolic or diastolic pressure. In the cases of permanently irregular hearts it is exceedingly doubtful whether one can obtain even approximately accurate readings.

In cases of uncomplicated aortic insufficiency the diastolic pressure may be as low as 20 mm. Between 30 and 40 is a common enough finding. Moreover, the change from the third clear tone, which may be so loud as to be uncomfortable to the ear drums, to the fourth dull tone is particularly sharply defined.

CONCLUSION

We may affirm that there is both clinical and experimental evidence to prove that the point at which diastolic pressure should be read, when using the dial instrument, is at the point where the fling of the lever during the gradual lowering of pressure suddenly becomes less, or, better, with the auscultatory method, where the clear sharp third tone suddenly becomes dulled.

THE CLINICAL SIGNIFICANCE OF HIGH AND LOW PULSE-PRESSURES WITH SPECIAL REFERENCE TO CARDIAC LOAD AND OVERLOAD*

WILLARD J. STONE, M.D.
TOLEDO, OHIO

METHOD AND PURPOSE OF STUDY

The attempt has been made, in an analysis of comparative pulse-pressure observations in 170 persons, to determine what, if any, clinical significance was to be attached to certain high and low auscultatory readings. For convenience of classification, the patients have been grouped as in the accompanying tabulation:

Conditions	Number of Patients Studied
1. Normal circulatory conditions	61
2. Acute infections	26
3. Arterial hypotension	9
4. Arterial hypertension	51
5. Myocardial and valvular lesions:	
(a) With compensation	9
(b) With decompensation	14

The readings were taken as follows: With the patient t rest, compression was made with a 12 cm. arm-band nd the systolic pressure taken by palpation. The ompression was then released and, after an interval ufficient for reestablishment of the circulation in the rm, the stethoscope was lightly applied over the rachial artery below the arm-band. Compression was eapplied and the systolic pressure taken by auscultation. The reading was taken at the moment the first clear sound was heard. The compression was then gradually released and the various tone phases noted. At the point at which the third phase of loud tone became suddenly and markedly dull—the fourth phase—the diastolic pressure was taken. The pulse-pressure was taken as the difference between systolic and diastolic pressure.

The difference between the maximum pressure exerted by the kinetic energy of the blood-column and the minimum pressure or potential energy exerted by the vessel walls is the pulse-pressure. It represents the intermittent burden of pressure imposed on the arteries by the heart's energy in systole in order to force the blood toward the periphery and maintain the circulation. The pulse-pressure may therefore be defined as the amount of pressure exerted by the heart during systole in excess of the diastolic pressure. It measures the excess of dynamic, over potential, energy. For clinical purposes it represents the load of the heart. Under normal conditions it is approximately 50 per cent. of the diastolic pressure. The systolic and pulse-pressures represent myocardial values, while the diastolic pressure represents arterial resistance. Incidentally it may be mentioned that the pulse-pressure is that part of the heart's energy which produces the distention of arteries which is recognized as the pulse.

HEART LOAD AND OVERLOAD

The many factors make the interpretation of any given series of cases an exceedingly difficult problem. One is confronted with many seeming paradoxes. For example, in sixty-one normal persons with an average systolic pressure of 123 and diastolic of 80, the pulse-pressure average was 40. The amount of energy expended, therefore, to *maintain* the circulation in excess of that required to open the aortic valves and overcome the resisting pressure of 80, was 40. The normal load may therefore be considered to be 40/80, or 50 per cent. of the diastolic pressure. In twenty-one acute infection recovery cases, the average systolic pressure was 119, the diastolic 76, the pulse-pressure 42. The amount of energy expended, or load, necessary to maintain the circulation in excess of the diastolic pressure was therefore 42/76, or 55 per cent. On the other hand, *in five fatal acute infections*, the average systolic pressure was 102, the diastolic 68, and the pulse-pressure 34. The amount of energy expended, or load, was 34/68, or 50 per cent.

It is apparent, then, that the problem involves the consideration of other factors, such as the mass movement of the blood and the venous pressure. Three years ago, before this Section, Hoover[4] pointed out that "the systolic and diastolic pressure may be within normal limits and still the mass movement of blood be much impaired," as was evidenced by marked signs of myocardial inefficiency, such as a *positive venous pulse*, cyanosis, dyspnea and edema. This has been observed in some of the fourteen decompensated myocardial cases of this series. The mass movement of blood-volume was impaired without marked alteration in the systolic and diastolic pressures. On the other hand, it appears that certain significant facts have been disclosed in the study of these cases, for while the average diastolic pressure, within normal limits was 84, the systolic was 148 and the pulse-pressure 64. The amount of energy expended in systole, or load, to maintain the impaired circulation, in excess of the diastolic pressure, was therefore 64/84, or 76 per cent., an overload of 26 per cent. The same condition was found to exist in hypertension cases. In fifty-one patients, the average systolic pressure was 161, the diastolic 95 and the pulse-pressure 66. The amount of energy expended, or load, was 69 per cent., an overload of 19 per cent. This was especially noticeable in the forty-seven patients over 40 years of age. Their average systolic pressure was 171, the diastolic 100 and the pulse-pressure 71. The amount of energy expended in systole, or the heart load, was 71/100, or 71 per cent., an overload factor of 21 per cent.

The question immediately arises as to how long the heart integrity may be preserved under such conditions. It is apparent that many persons with high pressures, and many hearts with impaired valves, are not seriously embarrassed for many years, owing to the compensatory hypertrophy and increased capacity for work which fortunately follow. It should be emphasized that high systolic, with slightly increased diastolic, pressures and a corresponding increase in the pulse-pressure is a compensatory attempt on the part of the heart to adjust itself to new conditions.

Preceding circulatory failure, however, but while the myocardial efficiency is impaired, there may be an essential change in the readings, with a tendency toward equal or higher pulse-pressure than diastolic pressure.

In six of the fourteen decompensated myocardial cases, the pulse-pressure approached or exceeded the diastolic as follows:

[4] Hoover, C. F.: A Criticism of the Blood-Pressure Apparatus, The Journal A. M. A., Sept. 3, 1910, p. 815.

Case 1.—T. W., mitral stenosis with regurgitation, cardiac dilatation, perpetual arhythmia, dyspnea and general anasarca. The average diastolic pressure for six weeks before death was 63, pulse-pressure 79. The amount of energy expended, or load, was 79/63, or 125 per cent., an overload of 75 per cent.

Case 2.—J. B., mitral regurgitation, with dilatation of left ventricle, dilatation arch aorta (?). The diastolic pressure was 90 and the pulse-pressure 100. Sudden death occurred three days after this reading. The amount of energy expended was 100/90, or 111 per cent., an overload of 61 per cent.

Case 3.—Mrs. J. L., paroxysmal tachycardia, rate 172, heart-block (?), systolic murmur over apex, thrill over precordia, dyspnea, but no edema. The diastolic pressure was 95, the pulse-pressure 85. The amount of energy expended, or load, was 85/95, or 90 per cent., an overload of 40 per cent.

Case 4.—J. B, mitral regurgitation, with decompensation, diastolic averages 57, pulse-pressure 90. The amount of energy expended was 90/57, or 158 per cent., an overload of 108 per cent.

Case 5.—H. C., mitral regurgitation, hypertrophy of left ventricle, frequent extra systoles, dyspnea on slight exertion, influenza. The diastolic pressure averaged 46, pulse-pressure 49. The amount of energy expended was 49/46, or 106 per cent., an overload of 56 per cent.

Case 6.—Miss A. C., mitral stenosis with regurgitation, diastolic averages 85, pulse-pressure 70. The amount of energy expended was 70/85, or 82 per cent., an overload of 32 per cent.

The load in seven of the remaining patients with myocardial decomposition averaged 61.6 per cent., or an overload of 11.6 per cent.

MYOCARDIAL FATIGUE AND CIRCULATORY FAILURE

We may consider that under certain conditions the myocardial overload may exist for years with little or no evidence of decompensation. Judging from this small series of cases it would appear that when the overload factor exceeds 50 per cent., the patient may be in danger of myocardial exhaustion at any time of slight overstrain. In fact, a majority of the forty-seven hypertension patients past forty years of age, in this series, did not show clinical symptoms of hypertension until the overload factor exceeded 25 per cent. Some were quite free from symptoms when the overload was 50 per cent. but most of these were able to regulate their lives, free from the liability of overstrain. As a rule, the greater the overload, the greater the danger. The following cases are given as examples:

Case 7.—Mrs. W. J., aged 53, plethora, systolic 180, diastolic 130, pulse-pressure 50, heart-load 50/130, or 38 per cent. If the deductions given before hold true, we would consider this patient in greater danger of cerebral accident than myocardial fatgue because of the high diastolic pressure.

Case 8.—E. L., aged 63, with a history of earlier angina, systolic pressure 170, diastolic 85, pulse-pressure 85, has a heart load of 100 per cent., or an overload factor of 50 per cent. According to these deductions, he would be considered in danger of an impending myocardial decompensation at any time of overstrain.

In many instances it has been interesting to attempt to correlate the symptoms of failure with pulse-pressure observations.

Case 9.—Miss F. H., aged 22, exophthalmic goiter and a pulse-rate of 132, showed a systolic pressure of 145, diastolic 75 and pulse-pressure of 70. The heart load was 93 per cent., an overload factor of 43 per cent. She died in shock five hours after removal of one lobe of the thyroid, under gas-oxygen anesthesia, by a competent surgeon.

In brief, it appears that with an overload factor of 50 per cent., in which the pulse-pressure equals the diastolic pressure, the danger of myocardial exhaustion is impending. To this factor is intimately connected, in instances associated with rapid heart-rate, the fact which Henderson and Barringer[5] have shown, that at rapid rates the shortened diastolic period cuts short the relaxation of the ventricle so that the ventricle does not have time to fill completely and, in consequence, the volume of blood thrown out in systole is diminished. The mass movement of blood would thus be impaired.

While this study does not warrant one in offering any expression as to the sequence of events which actually occurs in myocardial fatigue, it has been interesting to observe that when the pulse-pressure falls rapidly, or a low pulse-pressure of from 15 to 20 is present, actual circulatory embarrassment has occurred. The rapidity of the fall undoubtedly has much to do with circulatory failure, although in what way, remains to be determined.

Case 10.—W. E., aged 60, came under observation with a systolic pressure of 195, diastolic 60, pulse-pressure 135. The heart load was 225 per cent., an overload factor of 175 per cent. The patient showed a left ventricle dilatation, with systolic murmur at apex, bigeminal pulse and general anasarca. Under digitalis and free purgation his general condition improved, with disappearance of edema, until three weeks later the systolic pressure was 152, diastolic 100, and pulse-pressure 52, entirely within normal limits. He died suddenly about three weeks later. The mass movement of blood must have improved with the decrease in heart overload, for the heart-rate was not rapid and still circulatory failure followed.

It is beyond the province of this paper to enter into the discussion of these changes even though the discussion of one phase of cardiac fatigue immediately concerns the discussion of all others. It appears probable, though, that when the load suddenly decreases, cardiac dilatation has occurred.

CARDIAC DEATHS WITH LOW PULSE-PRESSURE

In certain deaths with low pulse-pressure, the following conditions were present:

Case 11.—G. M., aged 37, streptococcus septicemia, with endocarditis, all valves apparently involved, pulse-rate 120 to 140, subnormal temperature for two weeks before death. Systolic pressure varied from 85 to 100, diastolic from 70 to 75, pulse-pressure from 10 to 25. The average pulse-pressure for three days before death was 20.

Case 12.—H. B., aged 54, abscess and gangrene of lung following pneumonia. Systolic pressure was 105, diastolic 85, pulse-pressure 20, eight hours before death.

Case 13.—C. D., aged 24, postdiphtheritic pharyngeal paralysis, vagus paralysis (?). Pulse at wrist 36, over precordia 120, systolic pressure 90, diastolic 70, pulse-pressure 20, twelve hours before death.

Case 14.—Mrs. R. A., aged 33, probable gastric ulcer starvation and nephritis. The systolic pressure was 115, the diastolic 100, pulse-pressure 15. An unfavorable surgical prognosis was given and the patient died two weeks later from inanition.

The pulse-pressure often reaches as low a point as twenty, without serious clinical evidences of myocardial exhaustion although it appears from this study that these patients are undesirable surgical risks and may be on the verge of actual circulatory failure.

THE PULSE-PRESSURE IN HEMORRHAGE

Henderson and Barringer have shown that in hemorrhage or circulatory shock the venous pressure is low. They believe that the so-called "critical factor" refers to the failure of venous supply to the right heart and that failure of the circulation in shock is due primarily to the abolition of venous, not arterial, tonus. It would seem that a lowered venous pressure would decrease heart output by lessening the pulse-pressure on the arterial side. In one patient, who died two days after recurring typhoid hemorrhages, the systolic pressure was 67, the diastolic 47, the pulse-pressure 20.

---

[5] Henderson, Y., and Barringer, T. B., Jr.: Am. Jour. Physiol., 1913, xxxi, 288, 352, 362, 399.

Wiggers[9] has shown that a progressive decrease in pulse-pressure indicates, as a rule, a continuance of hemorrhage.

It would seem that the three important circulatory factors producing death in such instances were:

1. The peripheral resistance is suddenly diminished, owing to the hemorrhage, with increased heart-rate such as occurs experimentally when a large vessel is severed in an animal.

2. With rapid heart-rates, the volume of blood thrown out by the succeeding systole is diminished, because of insufficient time for ventricle relaxation.

3. The respirations are then increased in an endeavor to maintain venous pressure sufficient to distend the right ventricle as rapidly as the duration of diastole allows. But the venous pressure is low in hemorrhage, with the result that the right ventricle fills incompletely, which would diminish first the volume output of the right ventricle and then the left ventricle. With a decreased volume output the load or pulse-pressure would be diminished. Cardiac death may occur at this point, or the rapid respirations may lead to increased carbon dioxid elimination with the result that the carbon dioxid content of the blood falls to the point below which the respiratory center is stimulated, and apnea results.

COMPARISON BETWEEN PALPATORY AND AUSCULTATORY READINGS

	Normal Circulatory Conditions		Acute Infections		Arterial Hypotension	Arterial Hypertension		Compensated Myocardial Lesions	Decompensated Myocardial Lesions
	35 Cases Under 40 Yrs.	26 Cases Over 40 Years	21 Cases Recovery	5 Cases Death	9 Cases Aver. Age, 37	4 Cases Under 40 Yrs.	47 Cases Over 40 Years	9 Cases Aver. Age, 36 Yrs.	14 Cases Aver. Age, 46 Yrs.
Systolic pressure, palpation, average	117	126	116	not palp.	101	142	167	120	145
Systolic pressure, auscultation, average	120	127	119	102	105	151	171	123	148
Diastolic pressure, auscultation, average	81	82	76	68	84	90	100	82	84
Pulse-pressure, average	39	41	42	34	22	61	71	41	64
	aver. 40								
Heart load, per cent., average	48	50	55	50	26	67.7	71	50	76

In one patient with severe pulmonary hemorrhage, occurring in glass blowers' emphysema and tuberculosis, the systolic pressure was decreased and the diastolic increased during the hemorrhage, with pulse-pressure lowered to 20, which was increased to 40 within a few hours after the last hemorrhage. In another patient with a flank stab-wound lacerating the kidney cortex, with severe retroperitoneal hemorrhage and peritonitis from puncture of the colon, the systolic pressure was 98, the diastolic 55 and the pulse-pressure 43 during the hemorrhage. After drainage of the abdomen and enteroclysis, the diastolic fell to 38, while the pulse-pressure was increased to 54. This was in accord with the observation of Hürthle that the pulse-pressure increases with a decreased peripheral resistance due in this instance probably to toxic vasodilator effects of the peritonitis. Shortly before death from peritonitis, the diastolic fell still further to 35, and the pulse-pressure was increased to 75.

THE PULSE-PRESSURE IN ANEMIA

In three instances the systolic pressure varied from 120 to 135, the diastolic from 60 to 85 and the pulse-pressure from 45 to 65. The patient with the lowest red count, 1,630,000, had the lowest diastolic pressure of 60, and in consequence the highest pulse-pressure, 65.

THE PULSE-PRESSURE IN CARDIAC NEUROSES

It has been noticed in several instances of so-called irritable hearts, due to tobacco, that there were marked variations in all readings. For example:

Case 15.—O. G., aged 20, showed a systolic pressure of 135, diastolic 80, pulse-pressure 55, heart-rate 96. Ten minutes later the systolic pressure was 125, diastolic 90, pulse-pressure 35 and heart-rate 90.

It appears that marked variation within short intervals in the pulse-pressure observations should make one think of the neurotic cardiac element.

THE PULSE-PRESSURE CHANGES DURING EXERCISE

Different writers on this subject have suggested that the diastolic pressure is not affected, as a rule, by exercise in tests of the functional efficiency of the heart, while the systolic pressure is increased. The following experiments were made in persons with supposedly normal circulations.

Case 16.—R. S., at rest, had a systolic pressure of 125, diastolic 95, pulse-pressure 30. After twenty bending movements the systolic pressure had increased 10 points to 135, the diastolic had increased 5 points to 100 and the pulse-pressure was 35. After forty stationary running-steps, the systolic was increased to 145, the diastolic was 105 and the pulse-pressure was 40. After fifty additional stationary running-steps the systolic pressure was 160, the diastolic 110 and the pulse-pressure 50. During these exercises the systolic pressure had increased 35 points, the diastolic 15 points and the pulse-pressure 20 points.

Case 17.—W. S., at rest, had a systolic pressure of 118, diastolic 80 and pulse-pressure 38. After twenty bending movements, the systolic pressure was 122, the diastolic 78 and the pulse-pressure 44. After forty stationary running-steps, the systolic pressure was 122, the diastolic had fallen 4 points to 74 and the pulse-pressure was 48. After fifty additional running-steps the systolic pressure was 120, the diastolic 72 and the pulse-pressure was 48. During these exercises the systolic pressure remained practically stationary, the diastolic fell 8 points and the pulse-pressure was increased 10 points.

---

[9] Wiggers, C J.: The Prognostic Significance of Pulse-Pressure Changes During Hemorrhage, Arch. Int. Med., September, 1910, p. 281.

In both instances the pulse-pressure, or load, was increased by exercise.

THE INTERPRETATION OF TONE PHASES

The various tone phases heard by auscultation over the brachial artery below the arm-band during compression may be described as follows:

1. First phase, a phase of clear tones which is soon replaced by the second and third phases.
2. Second phase, a phase of muffled tones with a series of murmurs.
3. Third phase, a phase of clear tones which suddenly becomes the fourth phase.
4. Fourth phase, a phase of dull tones.
5. Fifth phase, disappearance of all sound.

Korotkow,[10] who first introduced in 1905 the auscultatory method for the determination of the arterial pressure, believed that the point at which all tones disappeared, the fifth phase, marked the diastolic pressure. It has been shown by Lang and Manswetowa,[11] in 1908, and by Warfield[12] in 1912, that the diastolic pressure coincided with the point at which the third phase of clear tone became suddenly and markedly dull—the fourth phase. This point has been used to determine diastolic pressure in this clinical study.

COMPARISONS BETWEEN PALPATORY AND AUSCULTATORY READINGS

The palpatory method, as will be noticed from the accompanying table, gave, as a rule, slightly lower readings than the auscultatory method.

THE INFLUENCE OF HEART-RATE ON PULSE-PRESSURE AND SYSTOLIC OUTPUT

It has been supposed by many writers that the volume of systolic output could be expressed by the formula, heart-rate multiplied by pulse-pressure.

Clinically, however, the heart-rate in circulatory shock —in the sense of Henderson—*increases out of proportion to the fall of pulse-pressure,* owing to the central vasomotor influence. Two examples, among others, may be mentioned.

CASE 18.—P. B., who died in circulatory shock from typhoid hemorrhages, showed a pulse-rate of 120 and pulse-pressure of 20, equal to an output of 2,400 unit volumes. The observation the following day, three hours before death, showed pulse-rate 148, pulse-pressure 20, equal to an output of 2,960 unit volumes. His circulatory condition should have shown improvement according to the formula but such was not the case.

CASE 19.—G. M., streptococcus septicemia, pulse-rate 120, pulse-pressure 10, equal to an output of 1,200 unit volumes. The observation two days later, seven hours before death, following an intravenous injection of strophanthin, showed pulse-rate 140 and pulse-pressure 25, equal to an output of 3,500 unit volumes. According to the formula his output was increased, but death occurred seven hours later.

It is therefore believed that in circulatory shock the pulse-pressure multiplied by the heart-rate does not give a reliable index of systolic output.

CONCLUSIONS

1. The determination of systolic and diastolic pressures by the auscultatory method is to be preferred to the palpatory method for systolic and column indicator oscillation for diastolic, because of greater accuracy.

2. The readings are slightly higher by the auscultatory than by the palpatory method.

3. The pulse-pressure measures the energy of the heart in systole in excess of the diastolic pressure. For clinical purposes it represents the load of the heart. Under normal conditions it is approximately 50 per cent. of the diastolic pressure. The myocardial load may therefore be expressed by the fraction

$$\frac{\text{pulse-pressure}}{\text{diastolic pressure}} \text{ or } \frac{\text{P.-P.}}{\text{D.P.}}$$

4. Since the diastolic pressure measures the peripheral resistance it is a better index of hypertension than the systolic pressure. A sustained diastolic pressure of from 100 to 110 signifies hypertension. The diastolic is less influenced by physiologic factors than the systolic pressure.

10. The pulse-pressure multiplied by the pulse-rate does not give a reliable index of systolic output in circulatory shock since the pulse-rate clinically increases out of proportion to the fall of pulse-pressure. This shortens the time during which the left ventricle is filled during diastole and lessens the systolic output, although by the formula, pulse-rate multiplied by pulse-pressure, the unit volume output may appear to be increased.

It is a pleasure to acknowledge the suggestions and criticism of Dr. E. W. Jackson of Rochester, New York, in the preparation of this paper.

CLINICAL ASPECTS OF HYPERTENSION *

JOSEPH L. MILLER, M.D.
CHICAGO

While the question of hypertension has been thoroughly discussed during recent years, it is still one of the problems in medicine. With the introduction and general use of the sphygmomanometer, we have become acquainted with the frequency of increased blood-pressure, and have been able to follow its course; but the question of its etiology or pathologic physiology is largely undetermined. The present report is concerned merely with the present views of its etiology, a consideration of a series of cases observed during the past few years, and a brief discussion of the prognosis and treatment.

Arterial and renal changes have always been considered the most important factors in high blood-pressure. With our increasing knowledge of this subject, the importance of the renal factor has become more and more apparent, and coincidentally with this, lessened weight is attached to general arterial changes, especially if we exclude the arterial changes in the kidney. It is generally accepted that sclerosis of the peripheral arteries does not increase blood-pressure; and while it is acknowledged that involvement of the celiac axis or its branches, the great regulator of the blood-pressure, may give rise to hypertension, clinically this is probably a quite infrequent cause. The recent greater importance attached to renal lesion can be largely accounted for by improved methods of diagnosis of kidney lesions; or perhaps more accurately, it has been determined that apparently normal urinary findings do not exclude serious kidney involvement. The careful necropsy studies, and especially the careful histologic examination of the kidneys of patients with approximately normal urines, and high blood-pressure, have shown how fallacious it may be to exclude nephritis in the absence of albumin and casts. Especially in extreme hypertension, 200 mm. or more, some form of nephritis is almost constantly present, and is probably responsible for the increased blood-pressure.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

Kidney lesions are less frequently reported in patients with pressure below 180 mm., but it is scarcely probable that the lesser degrees of hypertension are due to different causes than those of extreme degree, but rather that the kidney involvement is less extensive and less readily detected. It is quite possible that as our knowledge of the morphology of the kidney advances and methods are developed for the detection of finer histologic changes, kidneys now pronounced normal may fall into the class of the definitely pathologic. We now believe that a kidney cannot be pronounced normal merely from its macroscopic appearance, as many of these histologically show extensive interstitial or glomerular changes. Our functional kidney tests show, as it were, only the grosser kidney lesions. It must furthermore be borne in mind, as bearing on this particular subject, that a kidney may be so affected as to modify the general blood-pressure and still show proper elimination of waste. The recent discovery of the importance of glomerulonephritis lessens greatly the value of any but the most recent report on the prevalence of renal involvement in cases of hypertension. Especially must we view with suspicion those cases in which the diagnosis of nephritis has been determined by merely a macroscopic examination of the kidney.

Fischer[1] has recently furnished an interesting report of 550 cases of hypertension in which the clinical and pathologic evidence of nephritis has been carefully considered. His series does not differ materially from others previously reported except possibly in the care with which the cases have been studied. Sixty-two per cent. of these patients gave definite clinical evidence of nephritis, 15 per cent. were suspicious, and only 23 per cent. had a normal urine. Excluding those cases with pressure below 160, in only 3.6 per cent. was the urine normal. Necropsies were held in forty-two cases and in each instance definite microscopic evidence of nephritis was detected; although in fourteen of these the urine did not show evidence of renal trouble. This furnishes very good evidence that nephritis cannot be excluded when the urine is apparently normal.

In Krehl's clinic 87.4 per cent. of the cases with pressure of 200 mm., or higher, showed definite clinical evidence of nephritis, and forty-two of the forty-three cases coming to necropsy showed definite renal involvement; the majority showed interstitial or arterial changes. Statistics of this character might be multipled, varying somewhat in the percentage, but all showing the predominance of nephritis in patients with hypertension, and also the greater frequency of the clinical evidence of nephritis in patients with extreme hypertension.

There remains, however, a few cases of hypertension in which with the most careful examination by our present methods the kidneys appear normal. In a few of these the increased systolic pressure can be explained by an aortic regurgitation, in others by marked arteriosclerosis of the splanchnic arteries; but there still remain a very few cases, which at present we refer to as idiopathic. Most of these, however, present only moderate degrees of hypertension.

Assuming that renal changes are usually associated with high blood-pressure, we must still determine in what manner the hypertension is produced. The view has been abandoned that primary heart hypertrophy is responsible for the change in blood-pressure. The heart hypertrophy is probably always secondary. There are still many supporters of the old Traube and Cohnheim view that the mechanical interference with the blood-flow in the kidney was responsible for the condition. Failure to produce increased blood-pressure by ligation of the renal arteries, or by experimental production of multiple renal emboli, does not disprove this theory.

The attempt has been made to explain hypertension through retention of waste ordinarily eliminated through the kidney. None of the substances, however, which are eliminated by the kidney have a pressor action when injected into animals. On the other hand, when the eliminating power of the kidney is impaired by successive removal of small portions of it, finally a point is reached at which the animal develops a polyuria and increased blood-pressure (Tuffner, Bradford, Passler, Heimicke, Janeway,[2] Carrel). In order to produce these results about two-thirds of the total kidney substance must be removed. It is impossible, however, to say whether these results can be accounted for by lessened elimination or mechanical interference with the renal blood-supply. While in uremia there is usually a nitrogen retention, it has not been shown that such retention is responsible for the increased blood-pressure.

Especially in acute nephritis there is considerable destruction of kidney substance, and the view has been advanced that perhaps the products of such autolysis might have a pressor effect. Tigerstedt and Bergmann, having reported that a pressor substance could be obtained from the rabbit's kidney, furnished some support for this view. Others, however, have failed to confirm the findings of a pressor substance in the kidney tissue, so that this theory lacks confirmation.

As the adrenals secrete a substance which possesses a decided pressor action, efforts have been made to associate hypertension with increased secretion from this source. Vacquez in 1904 reported hyperplasia of the adrenals in patients with high blood-pressure, but others have failed to confirm these findings. This does not exclude the possibility of hyperfunction of the adrenals, and the various tests developed for the detection of minute quantities of adrenal secretion in the circulating blood have been used in order to determine the presence of hypersecretion in patients with high blood-pressure. The recent investigations of this subject have failed to demonstrate in patients with hypertension an increase of epinephrin in the circulating blood. While there is no proof that the adrenals play a rôle in permanent hypertension, it is quite possible that the fluctuations in pressure due to worry, excitement, etc., may be due to modications in their secretion, as Cannon and others have shown that the adrenals in a cat become more active under excitement. Time will show which, if any, of the foregoing theories explain permanent high blood-pressure. At present, however, the nature of the process is undetermined.

In going over my office records, I found one hundred cases of hypertension with fairly complete histories of symptoms and renal findings. These were all ambulatory cases and so do not represent the terminal stages of this condition. With few exceptions, the patients have been seen several times, and in some instances have been followed for years. The urine examined was in almost every case a specimen passed at the office, making the test a rather more severe one than would have been the case if the early morning urine had been secured. As the urine was perfectly fresh, and had not been shaken by transportation, there was little probability of casts having been destroyed. In addition, in about one-third of the cases there were one or more analyses of a twenty-four-hour specimen.

[2] Janeway, T. C.: Nephritic Hypertension: Clinical and Experimental Studies, Am. Jour. Med. Sc., 1913, cxlv, 625.

The acetic acid and potassium ferrocyanid test was used for the detection of albumin. A drop from a centrifuged specimen was placed on a slide, and without cover-glass examined under low power for casts, and these reported present only when they were found with ease, one or more in each field. In this group of one hundred patients, sixty-four were males, thirty-six females. Forty-four were over 60 years of age, thirty-six between 50 and 60, seventeen between 40 and 50, two between 30 and 40, and one between 20 and 30. Thirty-three had a blood-pressure of 200 mm. or more, forty-five a pressure between 170 and 200, and twenty-two a pressure between 150 and 170. Albumin and casts were present in twenty-two (66.6 per cent.) of the cases with pressure of 200 or more, three showed casts without albumin, two albumin without casts, and in only six (18.2 per cent.) was the urine apparently normal. Forty-five patients had a blood-pressure between 170 and 200, twenty-one (46.6 per cent.) of these had albumin and casts, three casts only, one albumin only and twenty, or 44.4 per cent., showed a normal urine. Twenty-two patients with a pressure between 150 and 170 showed seven (31.8 per cent.) with albumin and casts, two with albumin only, three casts without albumin, and ten (44.4 per cent.) showed a normal urine.

Thirty-two of the one hundred cases have records of twenty-four-hour urine; 48 per cent. of these had 2,000 c.c. or more and 45 per cent. had 1,500 c.c. or less.

The frequency of renal involvement as determined by the urine, in this series, corresponds very closely with reports from other sources, and shows the great frequency of clinical renal changes in those patients with extreme hypertension. It is very probable that were the urinary examinations made with greater frequency, many of these patients with reported normal urines would show the presence of albumin and casts. Several cases in this list had repeated negative urinary findings, and then a specimen would be obtained which contained great numbers of short, narrow, finely granular casts. One of these patients with a blood-pressure of 200 has had during the past fou. years twenty urinary examinations, and has never shown numerous casts.

Briefly referring to the symptoms presented in these cases, seventeen of the patients were apparently entirely free from symptoms, referable to the high blood-pressure; fourteen of these were men, three women. The three female patients without symptoms had blood-pressures ranging from 165 to 185. Three of the men without symptoms had blood-pressures of 200 or more, one registering 220. Nocturnal polyuria was noted in sixty-five cases; all but two of these were males, and it is not improbable that prostatic irritability, rather than hypertension, was responsible in many instances for this disturbance. Angina pectoris was noted in twenty cases, headaches in ten, dizziness in eight, transitory aphasia or numbness in an extremity in eight, and marked eye symptoms were present in seven. Dyspnea was the most constant symptom, especially dyspnea on exertion.

The records show the cause of death in nineteen cases; this does not by any means include all of those who have died, as many of the patients have been lost track of. Broken compensation was responsible for death in twelve, angina in three, cerebral hemorrhage in three, and uremia in one.

The prognosis in high blood-pressure is of especial interest, as the laity has unfortunately become acquainted with the possible serious consequences associated with this condition. Cerebral hemorrhage, cardiac incompensation (including angina), and uremia are the most frequent causes of fatal termination. It may be, and usually is, exceedingly difficult in any given case to make a prognosis, on account of our inability to determine the strength of the arterial wall and the working power of the heart muscle. The functioning power of the kidney, and the dangers of a uremia, can be determined by the phenolsuphonephthalein test, an output within the first two hours of less than 25 per cent. of the phthalein furnishing evidence of grave renal involvement.

In obese patients, especially in women, a moderate increase in blood-pressure (from 160 to 170 mm.) may cause very decided dyspnea on exertion, or attacks of acute pulmonary edema. Many men, on the other hand, may be entirely free from symptoms with a blood-pressure of 200 mm. or more. The inherent strength of the heart muscle is an indeterminable factor and its ability to continue to perform an increased amount of work can be prognosticated in only a very general manner. The obese individual or person of sedentary habits is more liable to dyspnea from hypertension than those more athletically inclined. The patient who cannot, or will not, avoid physical or mental overtaxation is more liable to serious consequences than one who exercises care. The patient, however, with a pressure of 200 mm., or more, even with the greatest care, is liable at any moment to cerebral hemorrhage, or gradually developing cardiac incompensation; although a pressure of this degree is not necessarily inconsistent with several years of apparently good health. Transitory cerebral disturbances, as lapses of memory, aphasia, dizziness, or numbness in an extremity are an ominous symptom. Nocturnal attacks of acute pulmonary edema indicate that the endurance of the heart is being taxed to the limit, and the same holds true in patients who complain of dyspnea on moderate exertion. The appearance of moderate edema in the feet is of more grave significance in these cases than it would be in a patient with valvular trouble or a myocarditis, on account of the difficulty in restoring the cardiac compensation when its disturbance is due to high blood-pressure. The more marked the evidence of renal disturbance, the more grave the prognosis, on account of the actively progressive tendency of the hypertension, and the danger of uremia. Retinal changes, while of serious import, are not necessarily of such grave prognostic significance. Of extreme significance is the care the person is enabled to exercise, as freedom from physical or mental overexertion, protection from chilling, correction of habits, etc.

The patient, on the other hand, with a pressure of 170 mm. or less is not as a rule in any immediate danger, and with care in regard to diet, elimination, avoidance of overexertion and correction of habits may not only get along comfortably for many years, but may show a rather definite lowering of pressure. Patients with moderate degrees of hypertension are, I believe, much more liable to show a reduction in pressure as the result of treatment than those with very high pressure. It is in this class of patients that we are especially liable to see marked fluctuation in pressure, as a rule due to some inexplainable factor.

The drug treatment of hypertension is of much less importance than attention to elimination, dietetics and general hygiene. Even with our imperfect knowledge of the etiology of this condition much can be done to delay its progress and to prolong life. An effort should be made in each instance to determine certain possible etiologic factors and attempt their correction. On account of the great frequency of renal involvement, increased elimination through the skin and bowel is important.

While we are not at all sure that protein waste has anything to do with the increased pressure, nevertheless it is advisable with our present knowledge to restrict the protein intake, the degree to which this is carried depending somewhat on the apparent extent of renal involvement. We probably all would fare better if we did not use alcohol, tobacco or coffee; it is their excessive use that is especially objectionable, in both the normal person and the one with increased blood-pressure. In order to safeguard the heart all forms of severe physical exertion should be avoided. Excitement and worry, as they no doubt increase the blood-pressure, are to be regulated as far as possible. Moderate systematic physical exertion, on the other hand, may be beneficial to the heart. Golf in moderation, and on a fairly level course, or systematic walking is safe and beneficial for the patient who can do them without the development of dyspnea. Shortness of breath is the best index of physical overtaxation.

In the drug treatment, when evidence of cardiac incompensation develops, digitalis should be used in exactly the same manner as in any other form of cardiac incompensation. Digitalis, when administered by mouth, does not raise blood-pressure, and by relieving cyanosis may actually lower it. There is no good evidence to show that the iodids are of any special value except in those cases in which syphilis plays a rôle. They do not modify the viscosity of the blood, correct the arterial changes or lower blood-pressure. The various vasodilators, as nitroglycerin and sodium nitrite, have a very limited field of usefulness; their effect on blood-pressure is exceedingly transitory, and with the growing belief that the hypertension is a compensatory measure we are less and less inclined to rely on this group of drugs. At least, we all agree that their effects are merely palliative, while the hygienic measures referred to are directed at the underlying causes, as we now understand them. These measures are largely directed toward enabling the patient to live comfortably in spite of his high blood-pressure. If, on the other hand, we expect to reduce the blood-pressure to normal, we are in the vast majority of cases doomed to disappointment.[3]

122 South Michigan Boulevard.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. MILLER, WARFIELD AND STONE

Dr. Louis M. Warfield, Milwaukee: In the last two years I have been impressed more and more with the fact that the diastolic pressure is probably the most important feature in blood-pressure estimation. We see many cases of high systolic pressure which have lasted for years, and all of our conclusions in regard to the blood-pressure have been made from the systolic pressure. My impression, from the few cases that I have studied, is that it is not the high constant systolic pressure which is most important, but the gradually ascending or the high diastolic pressure. The heart compensates for the high diastolic pressure in the high systolic pressure, and the high systolic pressure is really, it seems to me, purely an effort on the part of the heart to maintain the circulation in equilibrium. If the resistance gradually increases there will come a time when the heart is working at its maximum capacity, and a slight strain will break this compensation. A large number of patients with chronic nephritis die from decompensation. The deaths in high pressure are similar in a way to those following intracranial hypertension. The same type of coma is present and at necropsy edema of the brain is found. Not enough attention has been called to this similarity. Much clinical research, checked by necropsy, must be done before we arrive at definite conclusions.

Dr. Stone's conception of the heart load and overload is a most ingenious and interesting one. I have been checking over some of the results of my records in the light of this overload factor, and have been somewhat surprised to find that this overload factor in so many of the cases has proved to be absolutely correct. That it is not correct in all cases one would, of course, naturally expect, but it seems to me that it gives us at present, at any rate, something on which we can work, and which will lead in the future to more accurate knowledge of what constitutes the overload on the part of the myocardium, because, after all is said and done, the myocardium controls the circulation, and any method we may have of measuring the load of the myocardium will give us tremendous advantage in diagnosis and prognosis of heart disease.

It is difficult to measure the systolic pressure and the diastolic pressure in cases of irregular and intermittent hearts. There will be a very strong beat, and several weak beats, and probably a little stronger beat and then a very strong beat, and it is practically impossible in cases of decompensation to measure the systolic and diastolic pressure. This does not seem to me, however, to be of great importance at that particular time, because in patients who are suffering from cardiac decompensation the diagnosis depends really more on the patient as we see him than on the blood-pressure. It is after decompensation has been established, however, that it becomes so essential to be able to tell the patient whether or not his heart is going to carry on his circulation for any length of time.

Other things being equal, a high diastolic pressure is of much greater moment in the prognosis than a high systolic pressure alone, and, if we are going to take one side of the picture only, I believe that it is more important to take the diastolic pressure, which measures the peripheral resistance, or the resistance the heart has to overcome, the work lost, so to speak, before it can possibly carry on any circulation at all.

Dr. Henry L. Elsner, Syracuse, N. Y.: The first class of patients to be considered are those with hypertension. Increased blood-pressure is in itself of little value, except as it teaches the clinician to keep a close eye on the patient, and this he must do tactfully.

When a patient presents himself with what might be called moderate hypertension, without any associated lesions, it is well for us to reassure him and send him on his way, with advice which will lead to right living, including moderate eating at all times.

A second class of patients consists of elderly people or those who are prematurely old who have hypertension with considerable hypertrophy of the heart, and yet, under these conditions, are often comparatively comfortable. They require reassurance and watching, never demand overmedication, and do not need continuous depressing autosuggestion.

The third class of cases includes patients with hypertension with positive renal changes but without marked symptoms. I have called these types of nephritis "non-albuminuric nephritis." The important fact to bear in mind is that it is not necessary in these cases to have albuminuria or casts and that these patients demand the closest care to prevent complications.

A fourth class of cases includes patients with very high blood-pressure, with positive renal symptoms, with marked arterial change, palpable thickened arteries and with a great many other symptoms. These patients demand our closest attention.

Of the iodids, or iodin preparations, and the nitrites, we are, I think, agreed that potassium iodid does the most, if any, good, but it ought to be given during a long period. The nitrites are really of no value, so far as the permanent effect on blood-pressure is concerned, but are of positive value for the relief of the sensory symptoms of arteriosclerosis, of hypertension, and especially in cases of stenocardia or angina pectoris and vascular spasm.

We should teach cardiac pathology based on the newer physiology. The graphic method leads to safer prognoses than we have ever made before. I have used the McKenzie polygraph with great satisfaction and have learned that in most cases of auricular disturbances the prognosis is fairly good, in spite of fluttering and delirium cordis. Ventricular disturbances are more serious.

Benjamin Rush made the statement in lectures delivered 125 years ago that "during his entire experience he had seen but one case of angina pectoris," and he says in parenthesis "I know of one other case which one of my colleagues in Philadelphia saw." When we consider the enormous number of cases of arteriosclerosis and stenocardia to-day we appreciate that the stress of modern living, competition, the use of machinery to expedite matters which invite haste, and wear and tear, with associated worry are the potent factors in producing degenerative processes.

Dr. W. S. Thayer, Baltimore: The study of blood-pressure is more important, perhaps, from the standpoint of prognosis than from that of diagnosis. The estimation of the maximum pressure alone is not the whole story. I was much impressed by what Dr. Stone and Dr. Warfield said with regard to the importance of the study of the minimum pressure, which is now easy and simple as a result of recent studies. In the tests in the beginning of the study of blood-pressure, the estimation of minimum pressure was not a simple matter. I wonder what my feelings would have been about one or two examples that I have used for the last three or four years to the students, one of them a man who came to me eleven or twelve years ago, now aged about 54 years, with a pressure of between 235 and 250. It was elicited with a very narrow band. He was much worried; he had some symptoms of vertigo; he had no evidence of nephritis. I advised him to be moderate in his general ways. I did not give him much besides small doses of iodids. He became tired of coming to me, and stopped treatment. He feels better than he used to, but his pressure is the same. I wonder whether or not my prognosis made eleven years ago was correct.

I agree with what Dr. Stone said about the therapy of cases of hypertension. I should like to emphasize the occasional danger of the free use of nitrites in chronic nephritis. I have seen one or two instances in which I felt sure that uremia was brought on by their use. A few years ago a man was sent to the hospital with a pressure of 220 and evidences of a slow chronic nephritis. He was given large doses of the nitrites; his pressure fell suddenly to 150 or 160, and he became anuric and comatose. After a week of vigorous treatment he came out of his coma, his pressure rose to about 200 and he left the hospital feeling well. Nitrites in this marked hypertension chronic nephritis should always be used with care and confined to the relief of headaches and other subjective symptoms.

Dr. H. S. Munro, Omaha, Neb.: If we study the problem of the composite individual we shall find that we have a syndrome in which we must consider the gastro-intestinal derangements leading to auto-intoxication—deficient elimination, with its resulting cardiovascular pathology, and the nervous symptoms which would logically accompany this syndrome. Then if we go down into the study of the psychology of the individual patient, we shall find that the diseased condition presenting itself is the end-product of all that has constituted the life of the patient, such as habits, quantity and quality of food, and vocation and other environmental factors contributing to the cause of the pathology found to exist. If we will approach the relief of these special pathologic entities in an indirect way, seeking to remove the cause of which they are the logical consequence, we shall do much more for the welfare of the patient than if we devote too much attention directly to the treatment of the special pathology. These conditions are often the result of abnormal social conditions, of misadaptation socially and economically. Quite frequently this class of patients has sought relief, and the nervous element attracted the most attention. I find always that high blood-pressure and cardiovascular lesions are associated with deficient elimination, autotoxemia and the abnormal habits, psychic and physical, corresponding to these end-results.

It is simply a question of inducing the patient to adopt healthful habits of life, after first administering a course of disintoxication treatment, in which fasting, exercise and psychotherapeutic measures have been my sole reliance. Rest in bed and overfeeding are never indicated.

Dr. J. M. Anders, Philadelphia: Dr. Miller well said that the subject of the clinical relation of hypertension has received a large share of professional attention recently and yet, because of the many unsolved problems connected with it, requires further study. He referred to an interesting and important class of cases in which there is no definite etiology and in which the cases are unassociated with any symptoms referable to the heart, the arteries or the kidneys. Because of the fact that a patient with simple hypertension presents no symptoms, the condition has been termed physiologic by certain English writers, notably Allbut. My own belief is, however, that the biologic chemistry of the future, together with further clinical study, will show that this class of cases will undergo a constant diminution. For example, it is quite evident that many cases of simple hypertension formerly considered physiologic are associated with latent kidney conditions; and again, others are associated or dependent on neurasthenic states. While certain authors regard these cases as having no assignable etiology and no symptomatology, let us not forget that if we study them with sufficient care we shall sometimes at least find a cause, or a combination of causes, that will adequately explain the hypertension. In my experience most of these cases occur in persons who are addicted to the immoderate use of alcohol or tobacco and are subjected to more or less nerve-strain; and I have felt repeatedly that this alcoholism and nicotinism, as well as nerve-strain, might explain the increased peripheral condition which always leads to hypertension, and thus furnish a basis for rational treatment. Again, constant hypertension in many cases, if they be watched long enough, will be found to lead to arteriosclerosis. This theory of Scheffer, Klotz and others, in explanation of arteriosclerosis is now accepted by many modern writers. Therefore, these cases of so-called simple hypertension constitute an important group, clinically considered. We have not been sufficiently impressed with the importance of recognizing the nervous element in the causation of many of these cases of hypertension, and particularly of fluctuating hypertension, and that in the treatment the most important item is absolute rest in bed for a period of several weeks at least, rather liberal feeding, massage and the use of the nitrites to combat certain sensory symptoms.

Dr. Thomas McCrae, Philadelphia: Regarding the opinion that in many cases of patients with high blood-pressure nephritis is latent, that is, without signs in the urine or anything to suggest clinical nephritis, it is important to consider what we mean by nephritis. If we say that a patient with high blood-pressure, whose urine is absolutely normal, has latent nephritis, we are losing all definite meaning of the term nephritis used clinically. A patient may have nephritis and go several days without urinary signs, but if he has a pressure of 225, is in bed for a month, and we examine all the urine, do the functional test two or three times and find that he is functionally normal, and then say that because that man has high blood-pressure he has latent nephritis, it seems to me that our diagnosis is open to question. You may quote pathologic figures which show a large percentage of nephritis. But what is nephritis on the necropsy table? You may ask the pathologist to draw the lines exactly, but the better pathologist he is, the more he hesitates to draw these lines. We must keep in mind that in persons over 50 the vast majority of kidneys show changes which one man may interpret as nephritis, and another may regard as the changes which occur with the advance of years. In correlating figures we must know what each particular pathologist terms nephritis. Where do the cases belong which occur in women about the time of the menopause, who have high blood-pressure for a year or two years, which later falls to normal, the urine being perfectly normal? Is there any suspicion of nephritis in some of these cases? I think not. It is a question whether or not we are justified in considering that high blood-pressure always means nephritis, in the absence of other definite findings.

Dr. W. W. Tompkins, Charleston, W. Va.: We are likely to emphasize the importance of symptoms by calling them too strongly to the attention of the patient.

Dr. Miller stated, if I understood him correctly, that digitalis given by the mouth did not increase the blood-pressure. I believe it has a contrary effect; that digitalis given by the mouth will increase the pressure as well as when given hypodermatically.

Dr. Walter L. Bierring, Des Moines, Iowa: It seems to me that there is much importance to be attached to the reference made to the nervous aspects of hypertension, particularly those attacks with lapse of memory, fainting attacks and very slight apoplectic seizures. I do not know just what Dr. Miller's explanation is for these. It seems that these attacks might be explained best by assuming the existence of vascular crises, intermittent closures of the vessels, as first described by Paul. It has appeared in the few instances in which subsequent examinations were possible that these particular nervous phenomena or cerebral arterial disturbances were most marked in cases in which there was an underlying nephritic disturbance or nephritic changes in rather definite arteriosclerosis or other arterial changes.

Dr. A. C. Griffith, Kansas City, Mo.: I am inclined to agree with those who have spoken of hypertension as due to some nervous phenomenon. In one case of hypertension the systolic pressure was 260 and the diastolic pressure 180. The pressure was reduced by rest, but no iodids of any description seemed to have any effect on the pressure. The patient, a woman about 60 years of age, was extremely nervous. The systolic pressure ran along from 260 down to 200 for two years. There was no change in the arteries, and no change in the kidney that could be detected by frequent examination of the urine. The functional activity of the kidneys was not changed at all by this hypertension; no dyspnea was particularly noticeable on exertion, and we could attribute the hypertension to nothing else than a neurasthenic condition.

Dr. Joseph L. Miller, Chicago: The subject which I discussed was permanent hypertension. I believe that nervous conditions are responsible for transitory disturbances of the blood-pressure, and that these disturbances of the blood-pressure may be of very high degree; but I believe that nervous influences are not commonly responsible for permanent high blood-pressure. I believe fully that pathologists disagree as to what constitutes nephritis, and Dr. McCrae made a very suggestive statement when he said that the patient should be kept under observation and the urine examined over a long period of time. I believe that, if we examine the urine of these patients with high blood-pressure daily, perhaps over a long period of time, and they show no casts, as a rule, we may be surprised to detect occasionally showers of casts. He also referred to his functional kidney tests in these cases. I am of the belief that, if we follow one of these patients with high blood-pressure and without casts or albumin through a long period of time, with daily examinations of the urine, and make repeated functional kidney tests, we shall find after all that the majority of them do show evidence of kidney incompetence, but I believe that as time goes by we are going to ascribe more and more of our high blood-pressure conditions to renal changes.

I have tried, repeatedly, taking the blood-pressure of patients several times a day for several days before digitalis was administered, then taking it several times a day for days when the patients were under the influence of digitalis, and I failed to find any material difference in the blood-pressure during these two periods of time. Furthermore, Cushney, working in conjunction with McKenzie, also maintains that digitalis administered by the mouth, at least in ordinary doses, does not affect the blood-pressure.

CANCER OF THE UTERUS

SOME POINTS TO BE EMPHASIZED IN THE EARLY DIAGNOSIS *

RUFUS B. HALL, M.D.
CINCINNATI

It is desirable to consider the diagnosis of cancer involving the cervix, and that involving the body of the uterus, separately. Therefore, I shall take up first the early symptoms of the disease involving the cervix, and later those involving the body of the uterus.

Cancer of the uterus has received more attention from gynecologists than any other disease peculiar to women. One must be convinced by study of the literature that the large part of this energy in the past has been directed toward the perfection of operative technic rather than to the more importnat problem of early diagnosis. The technic of the operation by the vaginal or abdominal route, or by a combination of both, has been perfected until little more is to be desired along that line. But what has the profession accomplished in the last decade in early diagnosis of cancer, that has benefited these patients? Scarcely anything at all.

While the men engaged in this special work have made advances in the early diagnosis of the disease, it does not benefit the great majority of these unfortunate patients, because we have not taught the family physician, who sees these patients first, to make the diagnosis in time for early operation. That many patients come to operation too late to promise a reasonable hope of cure, every operator of experience must admit. If an early diagnosis is to be made, it must be through the education of the laity by the family physician. From past experience I am convinced that the laity will not be educated until we can in some way bring home to the family physician his great responsibility. The propaganda for education of the family physician as well as the laity, inaugurated by the American Gynecological Association at its annual meeting in 1912, and more completely elaborated at the Washington meeting in 1913, should be commended and encouraged with enthusiasm by the entire profession.

---

* Read in the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

I have little new to offer but would emphasize some of the early symptoms of the disease that are so often neglected.

The importance of careful supervision over women regarding their sexual organs during the cancer period of life, which could be arbitrarily stated from 37 to 47 years, cannot be overestimated. I do not wish to be understood as saying that we may not encounter the disease in patients much younger or much older, but such cases are not nearly so often seen. The most trivial complaint, let it be discomfort in the pelvis or back, associated with a little watery discharge or leukorrheal discharge, or pruritus, during this period, should be investigated at once. The patient should not be permitted to go four or six months, or even a year, without an examination to determine the cause of these symptoms, as most of these patients are permitted to do now. before their physician examines them. During the past five years, for every case of cancer of the cervix coming under my observation early enough for an operation that justified the removal of the uterus, sixteen others came too late. For the five years just preceding that period, the ratio was one to twenty-one. In cancer of the body of the uterus the ratio was 1:4. The vast majority had consulted their physician several times, seeking advice for symptoms that were directly associated with the pelvic organs, such as pain in the back, irritable bladder, vaginal discharge or a little bleeding between the periods, and were treated expectantly without a vaginal examination being made or even suggested.

It is true that many of these patients did not apply to their physician for a vaginal examination but consulted him for advice. It is the family physician's duty however, to investigate every case in which the patient gives symptoms referable to the sexual organs during the cancer period of life, just as carefully as though he believed she had cancer, until he proves that she has or has not. When every physician realizes how important it is to the patient for him to do so, we have the key to the situation. We shall then have a great saving of suffering and prolongation of life for this unfortunate class of women. I am convinced that if these women were carefully examined by the family physician early, he would have little or no difficulty in convincing himself that the patient had cancer or that there was something out of the usual in her condition, and he would seek a consultation. Early diagnosis is of great importance to the family physician, in addition to the great good rendered his patient, because these patients and their friends invariably criticize his management of the case if he has delayed making an examination or has neglected to make one when they find that the disease has advanced beyond the operative stage. This criticism would be avoided if he investigated the case and made the necessary examination as it should be made at once, when the patient first applied for relief.

In the early diagnosis of cancer of the cervix, one should not overlook the fact that trauma due to childbirth plays an important rôle in the etiology of the disease. More than 98 per cent. of cases of cancer of the cervix occur in women who have borne children. Heredity does not appear to have as much bearing on the disease as it apparently does in carcinoma of the breast. Less than 10 per cent. of all cases of cancer of the cervix give a history of any member in the family having had cancer in any part of the body. A clinical record of every case examined by me is kept and filed. It is from these records, extending over a period of twenty-five years, that these deductions are made.

The early symptoms of cancer of the cervix, which I have observed in the order of their importance, are: (1) a watery discharge; (2) an irritable bladder; (3) a little irregular bleeding, and (4) a disagreeable odor. In reference to the watery discharge, I do not mean the ordinary leukorrheal discharge that women frequently complain of, but a watery discharge not unlike beef brine in its appearance. It may not be very profuse, but enough to stain the linen brownish. It irritates the vulva. It is more or less constant for a varying period of from five or six weeks to three or four months, before the patient considers herself ill. This is a most important symptom. If the history of the patient is carefully taken at the time, most of these patients soon after the watery discharge is noticed will give a history of irritable bladder; that is, they say that they must empty the bladder more frequently than before. They are relieved after the bladder is empty and they have little or no tenesmus. Where the patient could formerly go from four to six hours without discomfort, she now has to empty the bladder every two or three hours, and when she is unable to do this she is in distress. This is a most valuable early symptom and should be carefully considered. There is also associated with the watery discharge a vulvar pruritus in a large number of cases. Pruritus not associated with glycosuria during the cancer period of life should be carefully and immediately investigated to determine the exact cause.

The irregular bleeding amounting merely to a spot on the clothing between the periods is not an early sign of the disease, but it is one that should be immediately investigated. If the history of the case were taken at the time that the first bleeding is observed, there would be no difficulty in establishing the diagnosis of cancer, and that it has existed for a period of three or four months, or even longer. In almost every case it would be found that the symptoms enumerated had been present and observed by the patient for many weeks, in some instances for months, before the first bleeding occurred. Bleeding is not an early symptom. Many writers insist that one of the early symptoms of cancer of the cervix is irregular bleeding. It may be an early prominent symptom in some cases, but almost all these patients have other well-marked symptoms before the first bleeding is observed. The difficulty is to get the profession to place the proper importance on the apparently trivial symptoms. The disagreeable odor so much spoken of by most writers is a late symptom of the disease. This odor is from decomposition, a breaking down of the tissues. Necrosis must occur before there is the disagreeable odor for which so many doctors wait before they venture the opinion that the case is one of cancer.

Hemorrhage and pain come late in the disease. When the patient complains of severe pain and has had several hemorrhages, it will be found that she has passed the time when an operation for extirpation of the uterus would be of much permanent benefit.

One must differentiate cancer of the cervix early in its history from (1) erosion, (2) laceration, when the cervix is inflamed, (3) cystic degeneration, (4) tuberculous ulcer and (5) chancre. The diagnosis early is much easier than is generally supposed. When cancer is suspected from the history of the case, a careful vaginal examination is made by touch. If malignant disease is present, a small nodule is to be found. It is usually in the angle of a previous laceration and it can be distinctly felt as a little lump under the examining finger, entirely different to the touch from any other portion of the cervix.

In erosion, the entire cervix in every place feels exactly the same under the examining finger. Every portion of the cervix feels alike in a lacerated, inflamed cervix. There is no hard point the size of a bean or larger, and the entire ulcerated cervix feels alike. With a speculum the cancer appears different on inspection from the other tissues around. It bleeds more easily when touched with a probe. In erosion the whole cervix bleeds easily on touch and there is no hard point. In laceration every portion is alike. In cystic degeneration, under the examining finger one feels hard, round, small tumors, seldom one, usually several. On viewing the parts through a speculum, one finds that the cervix has the same appearance over the entire portion. There is no redness over these little hard bodies. When one is punctured by the knife, with the discharge of mucus the diagnosis is complete. It is hardly necessary to say that the examination would not be complete in any doubtful case without a microscopic examination of a portion of the diseased tissue.

Tuberculous ulcer is so rare, as compared with cancer, that the presumption would be in favor of cancer. The one case which I observed occurred in a patient who was far advanced in general tuberculosis. In that case there was no difficulty in deciding that the case was not one of cancer of the cervix.

From chancre, which is also comparatively rare, there should not be much difficulty in making a correct diagnosis. The sensation by touch is different from every other condition. The deep-seated ulceration, the hardened edge, with sharp, well-defined border, and the signs of syphilis in other parts of the body, should make the differential diagnosis in most cases exceedingly easy.

The early diagnosis of malignant disease of the body of the uterus is also very much neglected by the profession at large. Most cases are permitted to drift under palliative measures for a year, before cancer is seriously considered by the physician. The disease is so insidious in its onset, that if the first symptoms are observed within a year or two after the cessation of menstruation, the patient naturally attributes her symptoms to the menopause, and usually delays consulting her physician until the disease is far advanced. This form of cancer may and does occur in the maiden as well as in the woman who has borne children, which is not true in cancer of the cervix.

The disease is comparatively rare before the menopause. The majority of the patients whom I have seen were past 50 years of age. The earliest symptoms observed in these patients, by careful tabulation and review of their clinical histories, have been a watery discharge with a little bleeding (not a hemorrhage), at irregular periods, coming on several years after the establishment of the menopause. Associated with this discharge, every one of these patients complained of pruritus. Nearly every patient applied to her physician for relief from that annoying symptom, not suspecting that the discharge had any relation whatever to the pruritus. The discharge was not great enough to alarm the patient but enough to leave spots on the linen. As the disease progressed and after it had existed for from six months to a year, the bleeding, which heretofore had been just a spot on rare occasions, became more frequent and a little more in quantity, associated with a discomfort almost amounting to a pain in the back, or pain in the region of the uterus, or both. The pain comes late in the disease when the uterus is enlarged by the new growth, and the uterine muscle makes an effort to rid itself of the foreign body.

The diagnosis of malignant disease of the body of the uterus early in its history is not at all difficult, and there is no excuse whatever for this unseemly delay. With the clinical history, the physician should proceed to the examination. He will find that the uterus is enlarged, freely movable, and more sensitive than normal, with no perceptible disease of the cervix. If the disease is far advanced, the uterus may be greatly enlarged. A probe passed gently into it shows that the organ measures 3 inches or more in depth. The slightest manipulation of the probe will cause a free discharge of bright red blood. If a positive diagnosis cannot be made at this examination, it is the physician's duty to give the patient an anesthetic and explore the uterus thoroughly. He should curet it thoroughly and have a careful microscopic examination made of the scrapings. If this procedure is done, a diagnosis in a majority of cases would be made at the first curetting. If, however, a positive diagnosis of cancer cannot be made and the patient continues to bleed, in the course of six or eight weeks she should again be anesthetized and the uterus thoroughly explored and curetted, and a microscopic examination of the specimen made. Only on a few occasions have I been compelled to do a second curretting to confirm or disprove the diagnosis of cancer, when the clinical history and the symptoms justified that suspicion.

THEORETICAL AND PRACTICAL FOUNDATIONS OF A RADICAL OPERATION FOR CARCINOMA OF THE CERVIX UTERI *

EMIL RIES, M.D.
CHICAGO

The cause of carcinoma is at present unknown. Our knowledge of carcinoma in the human being is built up on clinical and pathologic observations. These have led to certain conclusions as to the growth of carcinoma, which may be summed up approximately as follows:

Carcinoma in its beginning is a purely *local disease* of a circumscribed group of epithelial cells. The tumor invades the host in two ways: first, by contiguity, and second, by the establishment of colonies or metastases, which are endowed with the same activities as the primary tumor.

The *contiguous growth invades lymph-channels* early and regularly, the blood circulation rather incidentally, irregularly and, we may say, less frequently. The primary tumor is subject to changes in two ways: first, degeneration, and second, infection. The metastases established especially along the lymphatic system are subject to the same changes, necrosis taking place in them and infection reaching them through the same or similar channels through which originally the carcinoma has reached them.

In the beginning, when there is no carcinoma in the patient's body except the original focus, a piece of tissue which comprises all of this tumor is a simple block of tissue by the removal of which, *theoretically at least*, the entire carcinoma can be eliminated. As soon as colonies have become established, a block of tissue which is to include the entire carcinoma must include besides the original tumor all the metastases or colonies. In order to excise such a block, we ought to have full and complete knowledge of all the metastases present in a given case. With our present methods this knowledge is absolutely unattainable. Therefore the outlines of the block of tissue which we have removed in carcinoma operations, and which we have hoped or intended to represent all the carcinomatous tissue, has been dictated by guesses as to the extent of carcinoma in the individual case rather than by exact knowledge.

---

* Read in the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

This block of tissue, which we may call the "carcinomatous block," is limited in one stage of our surgery of carcinoma of the cervix by the cervix itself, in a later stage by the outlines of the uterus and for the most advanced surgeon by considerably wider boundaries. We have enlarged the carcinomatous block in all carcinoma operations. The enlargement of the carcinomatous block in carcinoma of the cervix has been justified no less by the investigation of the specimens removed by the operation than by the improved remote results. It therefore has now a pathologic and statistical basis which was entirely lacking in 1895 when I first proposed this operation. But even to-day the delimitation of the large block is an arbitrary matter, and it is one of the fundamental weaknesses of all of our carcinoma operations that it must remain arbitrary so long as we have no means of preoperative diagnosis of the number and extent of the metastases, and therefore of the proper size of the carcinomatous block.

We consider the metastases of carcinoma to be derivatives of the original carcinoma, cellular constituents of which we believe to have been carried through the lymphatic channels to the lymphatic lymph-nodes. We also have concluded that it is necessary to include in the carcinomatous block all the lymph-vessels between the original focus and the metastatic focus in the lymph-node. We have been forced to this conclusion by the uncertainty as to what might happen if we cut across a lymph-vessel between the primary and the secondary focus. Two risks inherent to such operating have to be considered: first, the risk of leaving behind carcinoma metastases in a lymph-vessel which would lead to false recurrence, and, secondly, the risk of cutting through a lymph-vessel at a point where carcinoma is in its lumen and thereby spreading carcinoma in the wound, producing implantation recurrence. On the other hand we must not forget that these theoretical considerations are not any too well founded on actual observations. It is no exaggeration to say that hundreds of thousands of sections have been examined since 1895 by others as well as by myself. But in spite of this immense amount of material it has hardly ever been possible actually to demonstrate carcinoma in transit from the original to the secondary focus. Carcinoma in lymph channels in the immediate neighborhood of the primary focus, or in the capsule or near the capsule of lymph-nodes, has been demonstrated often by myself and others. But observations of carcinoma in transit at a distance from both the primary focus and the regionary lymph-nodes, say halfway between them in the broad ligament, are so rare as to be practically unknown. This is a point which deserves more consideration than has been accorded it so far. I am well aware, however, of the fact that it is practically impossible to recognize one or two isolated cancer cells in a lymph-vessel, and that therein may lie the reason why there are no extensive observations of carcinoma in transit.

In spite of this lack of actual observations of carcinoma in transit, it is absolutely logical to include in the carcinoma block not only the primary focus and the preferential seats of the metastases, but all of the intervening tissue as well; in other words, a prerequisite of a thorough carcinoma operation is that of continuous instead of non-continuous dissection.

The improvement in the results of operations for carcinoma in any part of the body can easily be shown to depend largely on this method of continuous, rather than discontinuous, dissection. Take, for instance, carcinoma of the breast and compare with it carcinoma of the vulva. The dissection of the carcinoma block in carcinoma of the breast is the best example of continuous dissection and the results are very fair. The operation for carcinoma of the vulva to this day is a shocking example of discontinuous dissection and its results are correspondingly miserable. In carcinoma of the breast every surgeon emphasizes the necessity of removing all of the tissue in one block. In carcinoma of the vulva the vulvar tumor is removed in one block, and, if the operator tries at all to be radical, the lymph-nodes are removed in one or two more blocks, so that altogether we get two or three blocks with intervening tissue left standing. It is not rational and the results are poor. As other examples of discontinuous dissection and poor results I may add the operations for carcinoma of the face, of the tongue, of the penis, of carcinoma of the extremities, especially Roentgen-ray carcinomas of the hands, carcinomas of the stomach, carcinoma of the gall-bladder. In all these, the operations performed usually are discontinuous dissections and in all the results are highly unsatisfactory. Improvement in results depends, therefore, not only on enlargement of the carcinomatous block, but fully as much on the method of *continuous dissection.*

It is evident that there are good reasons why the enlargement of the carcinomatous block and the continuous dissection are not available in all carcinomas. For instance, in carcinoma of the breast the carcinoma block, as bounded to-day and large as it is, is too small for many cases. Suffice it to mention merely the invasion of the chest wall, pleura, mediastinal lymph-nodes. On the other hand, the reasons for the discontinuous dissection of the primary tumor and the lymph-nodes in carcinoma of the face are also perfectly evident. Let us suppose a case of a carcinoma of the cheek. To make a continuous dissection, it would be necessary to remove the whole thickness of the cheek and the jaw and all the soft parts around the tumor in order to obtain one continuous block of tissue, including the primary tumor and the lymph-nodes of the parotid, under the jaw, in the neck, etc. Aside from the risks of such an interference, it is abhorrent to our feelings to propose such mutilation, the result of which would be almost worse than death.

In comparison with such an operation on the face the operation for carcinoma of the breast is far less mutilating even though the bulk of the tissue removed exceeds many times that removed by continuous dissection of a large carcinomatous block of the face. Also the risks attached are quite different. The operation for carcinoma of the breast as carried out to-day has very slight inherent risk. The removal of the soft parts is practically free from risk and the success of such operations is limited only by the accessory risks produced by the anesthetic, infection, air aspiration, etc. The moment we decide to increase the chances of radical cure by enlargement of the carcinomatous block, and remove, for instance, the whole thickness of the chest wall (as we often do in operations for recurrent carcinoma of the breast), the inherent risks become enormously greater, as well as the accessory risks. Collapse of the lung, displacement of the heart, difficult technic of closure of the wound have then become inherent risks of the operation.

Longer anesthesia and restricted function of the lungs are some of the increased accessory risks. The fact that continuous dissection is carried out might improve the remote results, but the gain might easily be offset, in part or entirely, by the increased inherent and accessory risks.

The accessory risks from anesthetic or infection carried in from the outside are the same in carcinoma of the cervix as in other carcinoma operations. But the gravest accessory risk in carcinoma of the cervix is that of sepsis from the infected primary tumor. I am not speaking of the infection which might be carried into the peritoneum by dragging the infected cervix through the abdominal cavity. Proper technic has reduced this risk to a minimum. But there are two other ways in which infection can gain access to the peritoneum and the pelvic connective tissue in the course of the operation. One is the much-dreaded tearing of the cervix, complete or incomplete, and the other is the infection of the field from crumbling lymph-nodes, which in addition to the carcinoma have been loaded with virulent germs from the primary focus. There is very little doubt in my mind (though I have not been able to confirm this suspicion by actual microscopic observations) that virulent germs may lurk not only in suppurating lymph-nodes, but in lymph-vessels in their neighborhood as well. Even if it is possible to clean up a primary carcinoma of the cervix fairly thoroughly before the operation, I can not see how this danger of infection from infected lymph-nodes or lymph-vessels can be deviated.

In carcinoma of the cervix the enlargement of the block to the limits which I indicated in 1895 has improved the remote results wonderfully. But the improvement was at the cost of increased inherent risks from hemorrhage, injury to ureters and establishment of large wounds in the connective tissue. At the same time it has not been possible to make the dissection in carcinoma of the cervix a truly continuous one. Though we attempt to remove the lymph-nodes and the pelvic connective tissue in one block with ligaments, uterus, tubes, ovaries and vagina, the small amount of tissue which surrounds the glands often renders this attempt abortive. In addition thereto, the dissection of the ureters out of the broad ligaments unavoidably makes a breach in the principle of continuous dissection. And this constitutes another weakness of the operation for carcinoma of the cervix.

This weak point could be eliminated if we could make up our minds to force the continuous dissection by including the ureters in the carcinomatous block and resecting them every time. The reason that we do not do so lies in the simple fact that there is a limit of tolerance, I am tempted to say, of the operator as well as of the patient. The operation for carcinoma of the cervix, as it should be carried out, is the most extensive operation I know of in surgery. I am sure that the carcinomatous block in this operation, as I carry it out, is as large as anybody has ever made it, but it is not so large as I should like to make it. In fact, I am considering its enlargement at least in the direction of the pelvic diaphragm and the paracolpium. This may mean greater demands on the tolerance of the patient, and it would be highly desirable to have some means of determining beforehand the limits of this tolerance in individual cases. But so far we have no reliable means of determination, not even in a negative way. It is surprising how sometimes emaciated, anemic, cachectic women stand the most extensive operations, while others who seem in comparative good health will succumb. Neither blood-counts nor urinary examinations, neither examination of the circulatory system nor any other methods that I know of, are reliable.

To-day the surgeon who operates for carcinoma of the cervix in the modern way is well aware of the fact that the size of the carcinomatous block and the method of continuous dissection on one side tend to improve his remote results to a degree never before attained but he is also aware that the inherent and accessory risks of such operations in the absence of reliable methods of preliminary determination of the limit of endurance are bound to increase his operative mortality. Operative mortality and remote results therefore have the tendency to show an inverted ratio.

The better the surgeon's technic the greater things he may dare. The world, and even parts of the medical world, not to mention the patients and their families, are utterly unaware of the difficulties encompassing such work. It requires sometimes a strong sense of surgical duty to persist in this most difficult and risky field. No man with any conscience will undertake such operations without extensive experience in abdominal surgery. But the prize is worth striving for. To this moment there is only one cure for carcinoma of the cervix—the operation; and my patients operated on from five to fifteen years ago and well to-day are the best witnesses to this fact. The statistics of all modern operators show a rich harvest of patients surviving for similar periods. Let me repeat: there is no other treatment of carcinoma that can show such results. Therefore it is to-day wrong and unscientific to withhold the chance of operation from any patient with carcinoma of the cervix or to waste valuable time with any treatment except operation, and this in spite of all risks which the operation involves.

32 North State Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. HALL AND RIES

Dr. J. H. Carstens, Detroit: One woman out of eight dies of cancer to-day. Think of that! Dr. Hall's paper is opportune and essential. I have been trying to do something in that direction. We must talk cancer day in and day out. You cannot impress the people, you cannot impress the profession unless you talk and talk and talk and show them the fearful results. They are careless, they do not think about it. I have been advocating for several years that we set aside one day in the year as cancer day; that all the newspapers write about cancer, that all the ministers preach about cancer and that all the lay press write and print "Cancer, cancer, cancer," so that the people will be aroused and the profession will be aroused and these cases will have early attention. Cancer starts locally microscopic and then is the size of a mustard seed. Found early it can be removed and that is the end of it; but you must look for it. The medical profession neglects these cases. In Michigan I tried for a number of years to get the state board of health to issue a cancer circular. This was finally done and a circular on the symptoms and how to cure cancer was sent to all the physicians and distributed among the people. Now they have started this work at the meeting in Washington. I went to the lay editors and told them about the fearful mortality from cancer and asked them to write and publish the matter and had them interview a dozen doctors, and they have written a number of articles and have stirred up the people about the cancer question so that they will be a little more vigilant. The point I have made is that if a woman has a slight discharge there is something wrong with her pelvic organs and she ought to give them attention. Some doctors are careless. I tell these women that if their doctor says, "Madam, I am going to examine you," and dissects away a little piece of tissue for examination he is a good doctor. That is the doctrine we must preach in season and out of season.

Dr. Walter B. Dorsett, St. Louis: I wish to say a word on the importance of making an early diagnosis of cancer of the body of the uterus. Dr. Hall spoke of the use of the curet by the family physician for the purpose of getting scrapings to make an examination. This I do not approve of at all. I believe that a physician should be ready to operate when he has done his curettement, not stir up matters to-day and operate next week. I am impressed with the importance of this matter from the knowledge of three cases. In one a physician attempted to curet with a sharp curet for the purpose of making diagnosis, and he punctured the uterus. The patient died. In another case I myself punctured the uterus with a curet, thinking that possibly I had a retained placenta to deal with. I immediately opened the abdomen, removed the uterus and saved the patient. Other cases of this kind have been mentioned. I believe that the curet is an instrument which can be used for diagnostic purposes under proper conditions, but whenever it is used the physician should be ready to do a major operation as soon as he has finished the curettement, if any accident should occur. Even if nothing has occurred, the operation should be done in a short time afterward.

Dr. G. Betton Massey, Philadelphia: I wish to emphasize the importance of what was said by Dr. Dorsett about the danger involved in making a diagnosis by the curet. That practice will probably be continued until surgeons act fairly on their own convictions of the parasitic nature of cancer. As was stated the other day by Willy Meyer in a cancer discussion in New York, pathologists still deny the parasitic nature of cancer, but surgeons regard the disease as parasitic. I wish to emphasize strongly my own conviction that if they believe in the parasitic nature of cancer they are acting wrongly to curet these growths. No cancer should be wounded until preparations are made for immediate destruction or removal. I submit that until the parasitic nature of cancer is disproved, the history of cancer operations reflected here, particularly in the pelvis, compels us to assume that it is parasitic, and to adopt such precautions in operation that these parasites shall not be transferred living to the cut edges of the wound.

Dr. William J. Mayo, Rochester, Minn.: I was particularly interested in what Dr. Ries said in regard to the foundation for an operation for cancer and the reason for doing a block dissection. I agree with him that up to the present time the experimental work on cancer in animals and plants has not been of great value as an aid to clinical diagnosis or to treatment, but I do believe that this work will finally lead to the solution of the cancer problem. We cannot experiment on the living human being. If those of you who are interested will go to the other side of this floor, you will see an exhibition of plant cancer, which to my mind is the greatest piece of research work on cancer which has ever been demonstrated. This work has been done by Dr. Edwin Smith of the Department of Agriculture, Washington. Dr. Smith has been able to produce, by a species of bacteria, cancer in plants which agrees in many essentials with what we know of cancer in the human being and of cancer in the animal which has been produced experimentally. These bacteria produce cancer, but only when there is traumatism or irritation at the point of introduction. He has shown that these bacteria stimulate growth in the plant; they respond by throwing out an unlimited number of embryonic cells, that is, a true cancer. In plant cancer the bacteria die and the endotoxins in their bodies stimulate the plant cell-nuclei, which take on a fresh growth, and this process goes on indefinitely. Dr. Smith's splendid work, taken in connection with Auer's work on cancer in chicken, gives an interesting picture. In his experimental work, Auer tried to produce the disease as we see it in the human being, but he could only cause tumor at the point of injection. He then added to the injection the skeleton of diatoms, which produced mechanical irritation of the tissues. He was then able to demonstrate multiple cancer lesions. No case of cancer of the skin has been reported that did not develop on a previous lesion. It must be the same in the internal surfaces of the body. It is to be found in the mouths of persons, both male and female, who chew the betel nut, and on the lip of the pipe smoker. It is prevalent in natives of Kurdistan on the skin of the abdomen, the result of heat irritation from the charcoal warmer they use. We have further examples in ulcer and cancer of the stomach, gall-stones and cancer of the gall-bladder, myomas of the uterus and cancer of the corpus uteri. It is said that the savage people do not suffer from cancer, which is probably not true, since their economic necessities make cancer the means of speedy death.

Dr. John B. Deaver, Philadelphia: I believe that in a certain proportion of cases of cancer of the fundus the pathologist in examining the scrapings, like the surgeon, makes mistakes in his interpretation. In those cases of uterine bleeding in which adnexal disease and gross disease of the uterus can be excluded, but in which there is question of doubt, I make a hysterotomy, and in this wise am sure of the condition of the interior of the uterus.

Dr. C. O. Thienhaus, Milwaukee, Wis.: It cannot be too strongly emphasized that a microscopic examination is the authentic proof of malignancy or non-malignancy. When the general practitioner sends a specimen of diseased tissue to the pathologic anatomist for microscopic examination he should know how to excise that specimen. He should not merely snip off a little piece of tissue, but should also see to it that the specimen for examination contains that part of the tumor or ulcer in which the normal tissue transgresses into the diseased tissue.

In regard to removal of glands in cases of cancer I should like to say this: Nobody removes a cancer of the breast without cleaning out the lymph-nodes in the axilla. Nobody removes a cancer of the tongue without paying careful attention to the removal of the lymph-nodes in question; nobody operates for cancer of the anus or clitoris without cleaning out the inguinal region. In the same manner in cases of cancer of the uterus the glands in the abdomen must be removed, and the removal of those glands has given the Ries-Wertheim operation the high standing and preference above all other operations for cancer of the uterus. Of course, often lymph-nodes may be swollen and still not be infected by cancer. This we find in cases of cancer of the stomach. I observed a case similar to that mentioned by Dr. Mayo this afternoon. After opening the abdomen I found a large immovable mass in the posterior wall of the stomach together with swollen lymph-nodes. I performed an anterior gastro-enterostomy, believing that the patient would die within two years. After three years, however, he walked into my office looking well and feeling well. Our diagnosis of cancer of the stomach was wrong. We had to deal with an ulcer.

Dr. John A. Lyons, Chicago: The cautery knife should be the instrument of choice in these desperate cases, in order to block the lymph-channels, prevent dangerous hemorrhage by plugging the blood-vessels and severe pain by sealing the cut nerve-supply. In these cases the knife, scissors and especially the curet should not be used.

Dr. Bertha Van Hoosen, Chicago: From the papers we have just heard we should be led to believe that the symptom of the first stage of cancer is a profuse discharge. I believe that the symptoms of the first stage of cancer are nil, and for that reason we shall have to do a great deal of educating of the public before we shall ever get cancer in its first stage. Not long ago a patient came to me with dysmenorrhea. I curetted as a matter of routine and sent the specimen to the laboratory. To my surprise the report was cancer of the body of the uterus. I thought that it must be a mistake, but proof was given from the examination of the specimen after removal. Shortly before that in another case I had removed a small piece from the cervix which was suspicious, but found no cancerous tissue. I proceeded on that diagnosis to amputate the cervix and do other plastic operations for prolapse. The removed cervix was sent to the laboratory and, in parts not suspicious, cancer was found. We are also taught a great deal about the age from 37 to 47. I saw within the last two years an inoperable carcinoma of the cervix involving the whole of the body of the uterus and all the lymph-nodes, and sections showed a far-advanced cancer of the cervix, in a patient not yet 20 years of age. I think, in view of some of these conditions, that it behooves the profession not to appeal so much to the laity, but to practice more routine examinations on all tissues removed from the pelvis, to discredit age and hemorrhage and to look for carcinoma everywhere and anywhere.

Three weeks ago I operated on a patient who had a small lump in the breast. It proved to be a medullary cancer. She also had a slightly enlarged prolapsed ovary. In this prolapsed ovary was medullary carcinoma. Panhysterectomy was done and the radical operation for the breast. Just exactly where the blocking of Dr. Ries comes in in this case I should like to have explained.

Dr. Henry O. Marcy, Boston: The cautery is used with much more safety if asbestos is employed to prevent the heat from being absorbed. I am reminded by the discussion that some years ago in my bacteriologic research work I developed an organism that without question originated in cancer. It "bred true" through several reproductions. Unfortunately, however, I failed utterly in securing its reproduction in the lower animals.

Dr. R. B. Hall, Cincinnati: I grant that Dr. Dorsett is correct in his statements that in these cases patients should not be curetted promiscuously. In my paper I did not speak of the curet in any sense in connection with the diagnosis of cancer late in the disease; I was talking about the early symptoms in these cases. This paper is made up of records of every patient I have had in my office in twenty-five years. These tabulated reports are absolutely correct. The symptoms mentioned in the paper do occur in the early history of cancer just as tabulated, and, if we get the profession at large to consider them, we shall make diagnosis of cancer of the uterus much earlier than heretofore. It is the general practitioner who first sees these cases, and he has the destiny of the people in his hands. I do not curet for diagnosis of cancer of the cervix. It is not necessary, as a rule. Cancer of the body of the uterus is a different proposition. In many cases it is not possible to make a diagnosis early in the disease without curetting. In the case in which there was perforation in the body of the uterus, disease had existed for a long time. There was a large cancer mass when the uterus was curetted. There was no normal uterine tissue left. That was not an early case; it was later in the disease. If one did occasionally perforate the uterus in his effort at a correct diagnosis, would it not be vastly better than to have this great number come too late for operation because no attempt had been made to make a correct diagnosis early enough to render the proper treatment? I think that it would.

Dr. J. F. Percy, Galesburg, Ill.: To me the most important sign is inability to move the mucous membrane over the cervix. I have never seen it mentioned in text-books. I do not believe that it is original with me, but it is a most valuable point. If one cannot move the mucous membrane over the underlying structures, malignancy is almost certainly present. Within two years a woman came to me with procidentia, a complete dropping of the uterus out of the vagina. On the cervix there was a small carcinoma. I cauterized that cervix merely by sticking one of my small cautery irons into the cervical canal. Then I fastened the vaginal walls to the broad ligaments, and removed the uterus. I felt comfortable, believing that I had done the right thing. Within six weeks that woman's pelvis was full of cancer, and within three months she died. I am getting cases after hysterectomy. Within five months I had a case in which the pubic region stood four inches above the level of the abdomen. The woman was cachectic and in a condition you can readily imagine. I stuck the cautery iron up through the vault of the vagina and allowed it to cook there for forty-five minutes. My assistant tried with his fingers to get around the mass in the pelvis. There were metastases in the liver and everywhere else. The woman recently died. but she died comfortably because I had inhibited the rapid progress of the disease. I saw a woman recently who was only 28 years of age to whom three different physicians had been giving local treatment for a year and a half. The only reason for discontinuing these treatments was that they caused so much hemorrhage that she became frightened. You can do nothing with the knife for a growth like that

THE RESPONSIBILITY OF THE DENTIST AND PHYSICIAN IN REGARD TO MOUTH INFECTIONS AND THEIR RELATION TO CONSTITUTIONAL EFFECTS *

THOMAS B. HARTZELL, D.M.D., M.D.
MINNEAPOLIS, MINN.

The human mouth is the largest portal through which infectious micro-organisms may enter the body. Almost all varieties of pathogenic bacteria have been found in the human mouth. The gastric juices afford little protection against them. Charles Mayo[1] says:

> Microscopic examination of gastric extracts made by Smithies from 2,406 different individuals with "stomach complaint" (dyspepsia, indigestion and the like) showed that irrespective of the degree of acidity of such gastric extracts, bacteria were present in 87 per cent. Morphologically cocci and diplococci were present in 83 per cent.; short and long rods (often of the colon group) in 58 per cent.; typical streptococci and staphylococci in 17 per cent., and *Leptothrix buccalis* in 24 per cent. In fifty-four cultural studies of saliva from "dyspeptic" patients, streptococci and staphylococci were demonstrated in over 80 per cent., bacilli in 66 per cent., and *Leptothrix buccalis* in more than 14 per cent. Comparing these figures it would appear that the common forms of pus-producing organisms (streptococci and staphylococci) have their proliferation retarded in gastric juice, but that bacilli (often of the colon group) as well as *Leptothrix buccalis* thrive in the stomach.

There is no protection to the organism where an actual lesion exists except that afforded by the leukocytes. The leukocytes in time are overcome in their effort to oppose the destructive effects of micro-organisms. The almost universal presence of small lesions contiguous to the teeth which afford foot-hold for pathogenic bacteria which by any chance gain entrance to the mouth, makes it doubly worth while to study the paths which the bacteria must travel to gain entrance into the circulation. A brief glance at the tissues in question will serve to accentuate the importance of a closer study of mouth infections.

ANATOMIC AND PHYSIOLOGIC CONSIDERATION

The teeth occupy sockets in the alveolar bone, which is built up around the teeth as they erupt. This bone is of a loose, porous character and has very thin edges; on the whole, an insecure frame-work to support the great stress of mastication, amounting to hundreds of thousands of pounds in the course of a year, which the teeth must bear. The teeth are suspended in their sockets by Sharpey's fibers, yellow elastic tissue, which is a ligament of suspension, plentifully supplied with blood through the alveolar process and also through the mucous membrane, the vessels dipping down into the ligament of suspension over the edge of the socket. In this membrane are resident certain glandular structures first described by Black. These glandular tissues are in direct continuity with vascular channels leading out into the mucous membrane and alveolar process. Therefore, any infectious material on the teeth themselves or accumulated between the teeth, at the free margin of the gum, has an uninterrupted avenue of entrance into the deeper structure of the jaw. The continuity of the vascular channels leading from the periodontal membrane into the deeper structures is readily demonstrable by the injection of pure oxygen gas under the gum margin by means of a blunt-nosed needle. In this way one can trace these vascular channels through the alveolar process for considerable distances. Therefore, the pyorrhea pocket, which is an ulcerating infected surface full of micro-organisms, or the alveolar abscess, which usually occurs in the apex of the socket around the root-end, are both capable of introducing into the circulation the severest types of infection. If we bear in mind the conical nature of the tooth-sockets and the fact that the tapering roots filling these conical sockets support structures which in every twenty-four hours of the ordinary individual's life may bear a stress of from five to ten thousand pounds, one readily comprehends how infections in the periodontal membrane or about the apices of the tooth's root are forced into the general circulation and lymphatic channels, leading from the teeth in their sockets. The direct lymphatic drainage of the tissues contiguous to the teeth is the most perfect in the whole body, affording direct access to the deeper structures of the neck, maxmilla and mediastinum, thereby making it possible for micro-organisms, introduced into the tissues through a pyorrhea pocket or apical abscess, to travel uninterruptedly into the deep structures of the body. Not only do the lymphatics afford direct access for micro-organisms to the circulation, but the rich plexus of blood-vessels supplying the periodontal membrane and alveolar process invariably suffer from the destructive activity of pus-forming bacteria, opening the blood-vessels themselves to the entrance of germs which are injected into the broken ends of these vessels by the powerful stress of occlusion during the act of mastication, thus making the spread of bacteria in the circulation a certainty. The elastic nature of the periodontal membrane makes it possible for the teeth to bear the shock of mastication for many years longer than they possibly could were they ankylosed into the bone. But this same elastic quality in the periodontal membrane favors the introduction of infection. For, if there is infectious material around a root end, or about the side of a root in a conical socket, and a weight of from 10 to 250 pounds is applied to the occlusial end of such a tooth, the elastic quality of the membrane permits the tooth to sink down in its socket so that the root acts as a plunger, injecting the infectious material into the surrounding tissues.

---

* Read in the Section on Stomatology of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

[1] Mayo, Charles H.: Constitutional Disease Secondary to Local Infections, Dental Review, April, 1913, p. 281.

The teeth themselves afford many square inches of surface for bacterial protection and growth, as they measure in a full denture about 20 linear inches in circumference, and, where destruction of the bony socket attains a depth of an eighth of an inch, we have the equivalent of 2½ square inches of cultural space beneath the gum margin. The necks of the teeth above the gum margin, protected from attrition by the broad bell-shaped occlusal portions of the teeth, afford easily from 2½ to 3 square inches more space on which bacteria may accumulate. This bacterial accumulation on the necks of the teeth is rarely noticed or appreciated, unless some special method of staining is adopted to reveal the presence of micro-organisms. If one desires to appreciate the enormous possibilities for bacterial growth on the necks of the teeth, one should apply a stain which will at once bring into view the bacterial coat always present on these surfaces.

STAINING METHOD

The best disclosing stain for revealing bacterial presence on the tooth's surface is iodin, 45 grains, zinc iodid and potassium iodid, of each 15 grains, water and glycerin, of each 4 ounces.

A cotton sponge dipped into the disclosing stain and applied to the necks of the teeth instantly brings into view a heavy brown coat on the teeth, which, before the application of the stain is made, may seem white and clean.

I advise physicians and dentists who are in doubt as to the cause of the marginal inflammations of the gum and underlying bone to apply always the above disclosing stain, after which the mouth should be rinsed with water, which will leave in clear relief whatever bacterial coat the teeth may at that time bear. If this practice is followed, the observer will be impressed with the constant presence of areas of inflammation and deep pockets of destruction in the alveolar process and bone contiguous to the necks of those teeth which bear the heaviest bacterial coat.

PATHOLOGY OF MOUTH INFECTION

The enormous surface for bacterial growth on the teeth and the protected areas between the teeth and the deep pockets which form in the presence of the heavy bacterial coat which these protected surfaces usually bear, give rise to a multitude of organisms, which of necessity pass into the stomach and bowels, and frequently alter, by their products and presence, the whole chemistry of digestion, so that an infected mouth may produce four distinct pathologic effects as follows:

1. That produced by the dissemination of bacteria through the medium of lymphatic drainage.
2. That produced by bacteria through the open blood-vessel.
3. That damage sustained by the individual through the change in the chemistry of digestion caused by bacterial poisons.
4. That produced by a general bacteriemia which not infrequently is a direct result of the dissemination of bacteria in the blood-stream.

I would not contend for a moment that all the ills to which human flesh is heir may be traced to mouth infections, but I have observed many cases of general infection of different characters which have been traced directly to mouth infections. The ordinary mouth infection may result in the loss of the teeth only, and the general harm resulting from such infection may be only slight. Statistics gathered by me show that there is about one case in every ten in which severe constitutional lesions occur, lesions which are usually overlooked both by physician and dentist, traceable to the mouth. I present herewith the analysis of one thousand and twenty cases of mouth infections:

SUMMARY OF FINDINGS IN 1,020 CASES OF MOUTH INFECTION

It is to be remembered that in the locality in which this experience has been gathered, the population is a young and vigorous one, as compared to the population of older countries, and the death-rate is lower per thousand on account of this fact. Here, the proportion of aged people to people under 40 is much less than that of older localities. Of the one thousand patients observed, few were bed-ridden. In the following deductions, these facts were kept in view. Over half, or, to be accurate, 600 seemed to be absolutely healthy and normal in every way except in the matter of teeth and gums. Caries was more or less prominent in the whole number, and marginal infections, with a greater or less destruction of alveolar process, were common to all of them. There were no marked physical symptoms of ill health, aside from indigestion or mild forms of gastric irritation. As a rule, on correction of the mouth infection, all these symptoms disappeared. Of the remaining four hundred, 300 gave evidence of more severe physical disturbances, though not severe enough to warrant sending them to a physician, or a more careful scrutiny of their habits of life than treatment of the mouth lesions and the proper rebuilding of the masticating mechanism. In the remaining 120 cases a great variety of physical ailments was observed, and physical examinations were made. The following lines of inquiry were noted and any facts which such inquiry elicited were tabulated: occupation, habits, general systemic condition, temperature, urinalysis, oral history, condition of the nose and throat, quality of the saliva, occlusion, the presence or absence of deposits on the teeth, and the character of such deposits, if present. Note was also made of undue stress, loss of function, prosthesis existing, and the prosthesis needed. The urinalysis involved a consideration of the total bulk of urine in twenty-four hours, its specific gravity, and examination for albumin, sugar, and a search for casts. The physical examination further sought to reveal or explain the systemic conditions which were found to exist in each individual case.

In eighty of these cases, the disturbance ranged over the entire alimentary tract, some patients being chronic sufferers from constipation, others from the opposite condition, namely, looseness of the bowels and diarrhea, all evidencing more or less malnutrition. Fifty had periodic and severe migraine, and the whole group suffered from more or less nervous irritation. Forty were of the extremely neurasthenic type. A considerable number of this group of 120 were also sufferers from chronic abscess. To be accurate, thirty-five had chronic apical abscess, and twenty had severe pericemental abscess as well. Sixty of them gave a history of rheumatoid pains, called by some of them neuralgia, by others rheumatism. In eighty cases, no kidney involvement or abnormal change in the urine was observed. Without exception all were benefited by treatment, showing a marked recession of constitutional symptoms on removal of abscessed and hopelessly loose teeth, and on surgical treatment of those teeth remaining which were worth treatment, followed by careful postoperative care of the mouth. Of the remaining forty cases, all showed greater or less kidney involvement, ranging from a trace of albumin to a considerable amount, with casts. Ten showed the presence of sugar. Twenty showed specific gravity of urine ranging from 1.020 to 1.035. Twenty revealed decreased specific gravity, with a corresponding increase of bulk in the twenty-four hours. Three were suffering from septicemia, and died of septic endocarditis. One died of septicemia without heart involvement. This was a recent case, in which bacteria were found in the bloodstream on culture, which bacteria were identified with those found in the pockets about the teeth, and also in an area of necrosis located about the two upper central incisors. Of this group of forty, twenty patients had pronounced joint involvements, ten of which were distinctly improved by treatment; one might, in fact say, cured. Five were improved and five not benefited. Of these forty cases, nineteen patients showed albumin in the urine before the mouth infection was attacked, which cleared up after the stamping out of the mouth infection. One of these patients had been suffering from ulcer of the stomach, the diagnosis of which was made by an exceedingly competent medical adviser, and was of two years' standing, though believed to be much longer. In this particular case, albumin was present in the urine. This patient suffered an intractable constipation, accompanied by a marked failure of stomach digestion. He yielded to treatment readily and after a period of two months gained in weight over 20 pounds, and lost all evidence of tenderness in the abdomen over the area where stomach ulcer was believed to exist.

A recent case is of great interest. The patient, a banker, suffered severe pain in two of the lumbar vertebrae, accompanied by pain and soreness in the wrist, elbow and finger joints. He made no material improvement until several abscesses, abscessed teeth, and pus infections in pyorrhea pockets were eliminated, after which he made a fairly rapid and satisfactory recovery. This patient was a man 58 years of age, and the total period of his incapacity from business had been eight months. For four months of this time his suffering was exceedingly acute, being bed-ridden. On account of the great tenderness in the vertebra, he was allowed to turn over in bed only once in twenty-four hours. Tuberculosis was not present. None of the symptoms bore out such a diagnosis.

In another case, the patient, a man of 62 years, suffered from a persistent and destructive inflammation of his left eye, having continuous pain for months, gradually losing the sight of the eye, and suffering intense pain radiating from the eye to the occipital region and down into the neck and shoulder. An abscess was finally located in the lower mandible near the mental foramen, involving the inferior dental canal. The opening of this abscess resulted in complete freedom from pain and a fairly rapid recovery after an illness of five months. The patient regained his bodily strength and vigor, but never regained the sight in his left eye.

There really seems to be no function or tissue of the body which may not be reached by infections occurring in or originating through lesions in the oral tissues. It seems eminently proper, therefore, that physicians should scrutinize more closely the mouths of their patients in all their routine examinations; insist on radiographic examination to discover impacted and diseased teeth; and insist on the extraction of diseased teeth, unless the patient is in the hands of a competent dentist who comprehends the vital relation which diseased and impacted teeth bear to the general health of the individual.

ABSTRACT OF DISCUSSION

Dr. Joseph Head, Philadelphia: The time has come when the dentist no longer considers as his chief work the restoration of teeth for the purposes of mastication. His primary work in the future will be to rid the mouth of infection, in order that the system may not be subject to diseases that, with the proper method of treatment, could be prevented. The point which Dr. Hartzell made, namely, that physicians should examine the mouths of patients to see if pyorrhea is present, is well taken, but I would add that dentists must feel that the examination of the mouth for infection takes the most subtle discrimination and analysis and requires all the technical skill and special knowledge of a dentist and a medical man combined. I had an interesting case in point a few weeks ago. A doctor came to me with a tonsil enlarged to three times its normal size and told me that he thought that he had pyorrhea. I looked into his mouth and it seemed perfectly healthy. There was apparently no disease of the gums. Finally, I probed between the wisdom tooth and the twelve-year molar; the probe went up past the buccal roots into a large pocket. The patient was particularly anxious that I should make a vaccine, so I took the proper amount of material from the walls at the base of the pocket and then made an application of ammonium bifluorid to the pocket. In a week the patient came back with the expectation of having me use the vaccine, but when I looked into his mouth I found that the tonsil had been reduced to its normal size and there seemed to be no other condition of infection present. The pyorrhea pocket was cleaned up. When the contamination from the tooth was removed the tonsil regained its normal condition.

Dr. T. L. Gilmer, Chicago: I think that the pathology of the teeth has been pretty well understood in the past, but aside from this the mouth has received insufficient attention. The average mouth may look healthy, but I venture to say that, if a narrow, very thin explorer is passed between the teeth and gingivae, hardly a mouth will be found without some pockets about the roots of the teeth. These pockets arise from slight traumatism. We often find in the lingual gingivae of the upper central incisors slight injuries which become pyorrhea pockets. Had these injuries been found in time and the cause removed, a more serious infection, or a pyorrhea pocket might have been obviated. Fortunately of late a real interest is being exhibited by dentists in the condition of the mouths as well as the teeth of their patients.

The members of the Northern Illinois District Dental Society are making a systematic examination of mouths to determine the extent of pockets about the teeth. This must lead to good results. When the physician more fully comes to realize the dangers from foci of infection in the mouth, which not infrequently leads to serious pathologic manifestations in other parts of the body, he is going to examine the mouths of his patients more carefully. The average practitioner of medicine is not sufficiently skilled in oral examinations to make a really critical examination of the mouth. He should supplement his work, when he suspects that the mouth may contain a focus of infection, which may be the cause of disease elsewhere, by calling to his assistance a well-qualified dentist, just as he would call in a rhinologist or an ophthalmologist if he wished the nose or the eye examined. On the other hand, the dentist ought to look more carefully into the physical condition of his patient when he finds chronic infections in the mouth to determine whether the oral condition may not have caused some manifestation of disease, in order that he may refer the patient to a skilled general practitioner, if necessary. All diseased and unclean mouths should be made clean and healthy. This ought to be done regardless of the loss of teeth. Teeth are very important organs and should not be removed ruthlessly, and most mouths may be made healthy and the teeth saved, but health and life are much more important than teeth.

Dr. F. B. Moorehead, Chicago: There is a definite antecedent in this condition which we are trying to correct, I think, by working at the wrong end. When I was a student the emphasis was not placed on the possibility of the mouth as a disease-producing factor, but on the necessity of a fine gold filling, of accurate adaptation, of partial plates and full dentures, and the accurate construction of crowns and bridges. We do not gain anything by criticizing our forbears. This is a matter of evolution. Therefore it is not proper to condemn the dental profession of those days, but it is only fair to say that they gave insufficient attention to the pathologic side of the profession and overemphasized, overstated, the mechanical side—if you can make that distinction. This attention to the mechanical side was born and bred in them as students, and it is difficult to get away from such training unless one is a student all through life. One may go into a dental college infirmary to-day and witness students at work putting crowns and bridges into mouths that are in a terrible condition, the teeth covered with tartar and pyorrhea pockets filled with pus. I am not overstating the facts. Our schools should insist that after the student has relieved the patient's suffering he must see that the tissues in the mouth are made healthy before he attempts anything in the way of construction of mechanical aids to mastication. If this is emphasized and insisted on the student is going to get the point of view that he should have. Then we must demonstrate to our students the infections that are being discovered to-day that can be traced directly to the mouth. It is possible, of course, to overstate the question and do ourselves harm by saying that the mouth is responsible for everything; but the statement that the mouth is, perhaps, the most important single avenue of infection in the body will, I believe, bear close investigation. There are, however, other avenues of infection — the adenoid tissue, the tonsil, the pharynx, the prostate and many other areas that must not be lost sight of. The work that is going to accomplish most in the future is the proper training of the dental student.

Dr. Nelson T. Shields, New York: If I remember correctly, Dr. Hartzell said that quite a large percentage of his patients were neurasthenics and that 40 per cent. of 120 neurasthenics showed the direct relation between the neurasthenic condition and infection in the tissues around the teeth. For the perfect treatment and care of the mouth all calcific deposits should be removed, and thorough prophylaxis should be established. If in that treatment a part of the root is exposed, the treatment is liable not to end there. If this should give temporary relief, well and good. If the patient should have an infected gum within a short period afterward, and the infection cannot be controlled by external applications or constitutional treatment, with the help of the physician, then you should look for the internal injury which would be within the pulp itself, because you cannot have an exposed root without having the calcific deposits within the pulp. This will induce an abnormal flow of blood through the arteries and also an immigration of leukocytes, which cause compression on the veins within the pulp, and this likewise causes calcification by irritating the odontoblastic cells. This classification, if the constitutional cause is not removed, will eventually cause the calcification of the entire pulp, which naturally means death to it. So that in the neurasthenic cases, gum infections are apt to be caused by the canaliculi extending entirely through the dentin to the cementum, and can be caused from within the pulp from constitutional causes as well as from local causes which are manifested on the outside of the teeth. In severe cases I would extirpate the pulp of such teeth, and after thorough cleansing of the root-canals mechanically, would fill them to their apexes with gold, and the remaining portion of the canals with the oxychlorid of zinc.

Dr. William C. Fisher, New York: I think that, without a doubt, we should excuse the teachers of years past on the ground of progress, but we cannot excuse those who are teaching the same things to-day. The members of this Section were recently invited to the meeting of a state examining board. One of the examiners took two or three of us to a chair and exhibited a new method of crowning. In passing a mirror around the mouth I saw one of the filthiest mouths I have ever seen in a clinic. A student was being taught to do but one thing in that mouth — to make some new character of cast crown that some particular skill has brought out. I remarked to the examiner, "My, what a wonderful case for a prophylactic clinic." He said, "Yes, it would be a rather good case for that, but we are just holding a crown examination to-day." What conception of dentistry can that man have if a state board of six men will license him to put a crown into a mouth without making any effort to remove the calcareous deposits and reduce the hemorrhagic condition of the gums? One lateral was almost completely hidden posteriorly by the congested gum; but that had nothing to do with the examination they were holding that day. How much better to say to a student or a graduate, "Here is a mouth; place that mouth in a healthy condition," and see what procedures he would take.

Dr. C. H. Oakman, Detroit: We who knew Dr. Harlen and who had the privilege of being his students know that prophylaxis was the fundamental teaching of his work, although he did not use the term prophylaxis. "When the patient enters your chair, examine the mouth carefully and see that the mouth and teeth are properly cleaned before any reparative work is done." This was his teaching; he was far in advance of the times and now, after twenty-two years, his teaching has become almost universal. Dr. Fisher just said that state dental boards are lackadaisical in some of their work, but we who have served on state boards for a number of years would like to do many things which are absolutely impossible. We cannot put a mouth into a hygienic condition when we have an urgent case to complete in a limited time. I think we are just awakening to a realization of the treatment of pyorrhea alveolaris. Possibly all of us, who have treated pyorrhea, have treated cases repeatedly and have met with no definite result. We discharge the patient after a dozen or more treatments, telling him to return in thirty or sixty days. At the expiration of that time the condition of the gums about the cervices of the teeth and other pathological conditions show that our progress in their treatment was quite unsatisfactory. I have in mind three cases of this kind which I treated. I had the urine tested and in one case found that the patient had 6 per cent. sugar and another 3½ per cent.; the third went to Carlsbad with 4 per cent., but after treatment there returned with the urine free from sugar. These cases were not amenable to treatment while the sugar condition was apparent, but after its elimination two of the cases readily yielded to treatment. I now make it a practice to have the urine examined in all suspected cases. Dr. Talbot says, and I think he is right, that a great many of the so-called cases of pyorrhea are no more than cases of gingivitis. There will be no pyorrhea if we can eliminate gingivitis early in the case. It is only when we allow that condition to persist that pyorrhea is developed.

Dr. G. V. I. Brown, Milwaukee, Wis.: I think that Dr. Fisher is unreasonable. He has evidently forgotten that these men are not teaching. They are supposed to let the applicants do as they wish to do, marking them accordingly. I think that it would be out of place for an examiner to take up that matter with the applicant. On the other hand, take the applicant's side: he has only a limited time in which to do certain things; there are a great many other things which he might do in his office. I think that when Dr. Hartzell undertakes to say what should and should not be done in this matter of oral hygiene he should remember that in order that this may be done to the best possible extent, an exceedingly delicate skill in diagnosis is required. It seems to me that that is the weak point in this paper, and that the purpose of this section ought to be in the direction of trying to make it easier for physicians and dentists to come together on a common plane, so that the knowledge of both may be applied in these cases and a great many of them relieved. For instance, I have just had a case of a little one who gave a history of a recent tonsillitis and of the injection during the course of treatment of large doses of antitoxin. After a short period of rest a swelling appeared which involved the region of the neck, the submaxillary region and all the regions to some extent behind and above the angle of the jaw; to complicate the condition still more a dentist had been consulted and had opened into a deciduous molar. The deciduous molar was then undoubtedly involved, whether or not it had been previously. At any rate, the treatment of the case through that deciduous molar, if it were an infection from the tonsillitis, would not have done any good. The patient's urine showed acetone, diacetic acid and albumin; in other words, that little child was in a condition in which the giving of an anesthetic was almost prohibitive. This is just the sort of thing that occurs when the physician and the dentist work separately. In this case a condition of things had been brought about in which it was almost impossible for anyone to make a diagnosis, and so I did what anyone would under the circumstances. The condition of the kidney was definite. I kept the child quiet, on proper diet and carried her through nicely. We finally found pus, and after its evacuation later—there were two or three ounces—we were pleased to find that in the culture it showed no growth.

Dr. William C. Fisher, New York: We had an address from our chairman yesterday which pointed out the great need for work along the lines of Dr. Hartzell's paper. We have all been talking of and wondering where we could get men to do this work, and we said that we would have to educate them. The minute a man criticizes what is being done by the state board, he is censured for it. Dr. Brown made the statement yesterday in private that if one hundred dentists were invited to this room, 25 per cent. could not discuss the papers here. They will not be educated to discuss these scientific papers if the making a crown is the main requirement for getting a license. I want to reiterate that I consider an examination of this kind unfair to the applicant and to his alma mater, and to the persons he is to serve. We do not want good jewelers. My hat is off to the prosthetic men; they did good work in the past. They laid the foundation on which we have built our profession. This side of our work should not be slighted, but the pathologic side is still being slighted by our state boards.

Dr. Truman W. Brophy, Chicago: The teachings of Dr. Hartzell's paper are living issues. They will be quoted by men in the profession everywhere. His conclusions, I think, are logical. The discussion which has followed has, it seems to me, been in part rather unfortunate. Dr. Fisher brought up a phase of the subject of prophylaxis which, it seems to me, should be carefully considered by this Section. I know quite well some things about dental teaching and the work that has been done for more than a quarter of a century in dental colleges, which have made American dentists famous throughout the world. I know that the American dental college professor in other lands is respected and regarded as an honorable man. We know that the good status of our profession to-day throughout the world has been due more to the work of the honest dental college professor than to any other factor, and as a dental college man, one who has spent the better part of his life in assisting in this great work of dental education, I regret that any man should criticize, not only the college man, but also the members of boards of examiners, who are working with all their might to advance the interests of the profession and protect the people from the charlatan. When a man stands on this floor and says that the board is neglecting what he believes to be a duty, he does not remember that for over a period of two weeks this board has been laboring hard with these men right along the very lines that he says are neglected. More than one hundred candidates are here before the state board, as I understand it. They have not the time nor the opportunity here to enter into the study of pathology or carry out a long course of treatment. They have been through that in their written examinations, and to-day they are doing the practical work which the board demands. These are facts which we cannot overlook, and the members of the board are all to be commended for their self-sacrifice, their devotion, and their earnest labor to see to it that these men, now having completed their written examinations and answered all the questions as best they knew how, are now tested as to their practical merits.

Dr. A. T. Rasmussen, La Crosse, Wis.: This controversy regarding the duties of the state board makes me feel sorry for any state board. I was one of the men to take the examination in the state of Wisconsin, and I really cannot forgive myself for the way I treated that case. I knew it was wrong. I said to the examining board, "Gentlemen, it will never do." One member said to me: "We have no other patient; go to it." What the results were I do not know. We were short of material. One of the remarks Dr. Brophy made was in reference to practical things. I think that we ought to do away with the discrimination between practical and theoretical dentistry. Pathology is practical. We must have a working knowledge of pathology if we are going to treat diseases of the mouth, or any other part of the body. I am not criticizing anybody for the use of these terms. I use them myself inadvertently, but I think that we should aim to get away from the idea that pathology is not practical.

One other thing I wish to speak of is this: In some of these clinics there is no provision made for washing the hands, and it is not right for men to put their hands in the mouths of patients without washing them. If we will look after these so-called little things, the big ones will take care of themsleves.

I think Dr. Moorehead struck the keynote of the whole situation when he said, "unless we are students through life." Unless a man is a student through life, he has no business in the profession—either medical or dental.

Dr. C. H. Oakman, Detroit: For the inspection of the teeth of schoolchildren in the city of Detroit we have four dentists who never use a mouth-mirror. If an inspector uses one and it becomes known to the Board of Health, he will be censured. Instruments of any kind are not permitted in their work. Wooden tongue-depressors are used and discarded after being used but once. In this way there is no infection. Neither is it necessary for the operator to put his fingers in the child's mouth. It is impossible to make a thorough examination of the teeth in this manner. We do not intend to make as thorough an examination as if the patient were being examined at the clinic. If the mouth is unhygienic, teeth covered with tartar, food deposits, etc., it is absolutely impossible for an inspector to make a comprehensive examination. What we aim to do is to find the defects, and then refer the patients to their dentist or to the clinic. At the same time we place in the child's hand a pamphlet on oral hygiene which it is instructed to take home, so that the parents may be enlightened on this subject.

Christian Scientists did not want the children's teeth examined by the medical department, so as soon as the child brought a note from the parent saying that it was not necessary to have the teeth examined, according to their way of thinking, they were not molested. But I think in all clinics where a wooden tongue-depressor can be used the mouth-mirror should never be used.

Dr. Thomas B. Hartzell, Minneapolis: I was informed by the secretary of this section that the section did not make a great bid for dentists as members, because the average dentist could not take part in a discussion and keep himself to the subject, and it has been beautifully demonstrated here to-day that this is the case. Two or three of you have not discussed my paper, so I will recapitulate briefly the thought of that paper and tell you why I wrote it. I wished to show that the mouth is the great portal of infection; that the continuity of lymphatic tissue leading from it makes it almost impossible for the remainder of the body not to be infected from it if lesions exist therein, and I wished to bring to the medical profession, as a profession, a group of statistics proving that about one in every ten persons suffering from systemic infections will show the portal of infection in the mouth. I did not say a word about pyorrhea or any other specific kind of mouth infection. I wanted to make evident that the mouth is a great portal, perhaps three or four times as great in importance as any other part of the body, and I wished to bring that up in such a way that my medical friends would believe it and give it the credit it should receive.

As to the question of the treatment of pyorrhea or any other type of mouth infection, I have nothing to offer in this paper, but I do wish to thank the men who have apprehended my idea and discussed that. I do not believe that the part of the discussion relating to methods or special diseases, pyorrhea, abscess or any thing of that kind, really belongs in a discussion of this paper. Medical men have come to think, and justly so, that dentists are greatly at fault, and have not sufficient scientific training, as was stated by Dr. Brophy and Dr. Moorehead.

If the medical profession realizes that dentists can do better work in this direction, they will unite in demanding of the dental profession that they must do it by setting an example in the way of extracting diseased teeth and condemning their confrères who attempt to do conservative work and at the same time foster infection. If this results, then my paper will have accomplished something worth while.

Suicide in Prussia from 1907 to 1911.—According to the National Statistical Bureau of Prussia there were 8,422 suicides in 1911 (6,394 males and 2,028 females) and in the previous year 8,179 (6,164 males and 2,015 females), an excess in the last reported year of 243. Probably this increase is due to the great heat of 1911, as experience shows that hot summers favor suicide. For the period from 1907 to 1911 the number of suicides per hundred thousand living varied between twenty and twenty-two annually. Among 1,000 suicides there were each year three to four times as many men as women. The tendency to self-destruction is of variable geographic distribution, depending much on race and religion. The frequency of suicide varies greatly also according to age, sex, family condition, profession and social position. It has been shown that the tendency grows with increasing age. The first decade may in general be regarded as immune, yet 1911 showed two suicides in children under 10 years.

INJURIES PRODUCED BY STARCH *

I. A. ABT, M.D.

CHICAGO

The *Mehlnährschaden* of the Germans, or the "starch injuries," have been extensively discussed in the German literature, especially in the writings of Czerny and Keller, and the Breslau school, and elaborated by the studies of Risel and Rietschel. To the genius of Czerny and Keller we are indebted for the conceptions of injuries to the organism produced by fat and starch and overfeeding with milk. These studies gave a great impetus to investigations of injurious effects produced by the component parts of milk. Thus, the ill-effects from excessive feeding of sugar, salts, starches, proteins and fats have been extensively studied.

In this brief clinical report I desire to review the work of the German authors on the starch injuries and to recite personal experiences. I feel it necessary to acknowledge that no original contribution is being offered, and feel that sufficient excuse for the publication of this report lies in the fact that few, if any, cases have been reported in the English literature.

This condition known to the Germans as *Mehlnährschaden*, seems to be little known in this country. Czerny and Kellar point out that starch in proper dosage is not injurious to the infant's organism. It has been suggested that nitrogen is better retained if small quantities of starch are added to the food. If it be given in excessive quantities for an extended period of time, particularly if it be used without the addition of milk, it may lead to disastrous results.

The condition arises in young infants who are fed starch preparations without the addition of milk. More frequently it is seen in infants who have suffered from a gastro-intestinal disturbance and for whom the physician has ordered a starch water, either barley or rice or oatmeal, and when this has been continued without the addition of milk, usually without the knowledge of the physician, for a long period. The pathologic condition which results from overfeeding of starch is due probably to an actual food deprivation measured in calories. The starvation is particularly due to the insufficiency of protein, fat and salts in the diet. The salts contained in the starch food as well as the starch itself, tend at times to combine with water in the tissues, leading to water retention. This causes the infant to appear plump, though pasty and pale. In the meantime, the normal production of antibodies in the organism is diminished and the resistance of the infant against infection is lowered, and secondary infections are likely to occur. Dyspeptic conditions with diarrhea and loss in weight result. If the condition of inanition continues for some time, fermentation and inflammation and loss of function of the alimentary tract are inevitable. This latter condition will explain the atrophic type of starch injuries to be referred to again.

The disease presents itself in three main types. Very frequently the little patients appear plump and are thought to be unusually well developed.

1. In cases in which there is a deficiency of salt without retention of water, complicated by diarrhea, the atrophic type presents. The muscles are hypertonic, the tissues dry, the skin and mucous surfaces are pale and the abdomen is distended.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

2. The hydremic type occurs most frequently in cases in which salt is added to the starch preparations, or in which a small quantity of milk is used in the food.

These children remain stationary or increase in weight; sometimes the increase is enormous. If considerable milk is added to the diet at this point, the infants lose rapidly in weight. If the starch diet is resumed an increase in weight occurs. Gradually they present an edematous, pasty appearance, due in part to retention of water, and in part to accumulation of subcutaneous fat. The musculature is doughy on palpation; the abdominal wall and lower limbs become edematous, not due to nephritis but to a condition of simple hydremia. Owing to the diminution of the natural immunity the infant is predisposed to infections, such as bronchopneumonia, pharyngitis, otitis, abscesses and phlegmons. Czerny mentions that xerosis of the conjunctiva and cornea with sequelae are not infrequent and the condition usually indicates a fatal termination. He notes that ophthalmologists recognize the fact that infants with this eye disease seldom survive.

3. The hypertonic form is the most infrequent type. The muscles become rigidly contracted and are stiff and board-like. On account of this condition the spine is like a rigid tube, the occiput is bent backward and is bored deeply into the pillow, the arms and legs are adducted, the forearms are flexed at the elbow and the joints offer resistance to passive motion. In the severe types rigidity is so marked that the patient appears like one in catalepsy. Galvanic excitability with pronounced symptoms of tetany may be elicited. The bowel movements are usually yellowish-brown and formed, and frequently show starch with the iodin test. In the severer cases in which fermentation has occurred the stools may become thin with a penetrating sour odor.

PROGNOSIS AND TREATMENT

The dangers resulting from starch injury are most frequent in young infants. Starch can be digested by young babies, but only in small quantity. The mortality in these cases is high. The greatest danger exists on account of the loss of the natural immunity and lowered resistance, rendering infections more possible. The atrophic form seems most amenable to treatment and offers the best prognosis.

The treatment consists in the administration of milk containing a moderate quantity of fat. Carbohydrate food, such as buttermilk mixtures, malt soup and cereal decoctions should be avoided. Best of all is breast-milk. Even with the use of breast-milk one should consider the damaged tolerance of the organism and small quantities frequently repeated should be administered; first 2 ounces, 6 ounces, 10 ounces per day increasing gradually. Even with the use of breast-milk the cure will not be rapid. There may at first be loss of weight. The period of repair may be protracted, the damaged normal immunity may be slow to return and the use of the breast-milk should be persisted in for a considerable period, at least until the patient shows increase in weight. If breast-milk is not available, it has been suggested to use small quantities of undiluted cow's milk, 1 to 2 ounces per day, gradually increasing to 3 ounces and eventually to 6 ounces; finally by gradual increase to 10 or 12 ounces. The deficient quantity of water in the food may be counterbalanced by giving tea or water sweetened with saccharin. Or the milk may be used diluted with water, small quantities being frequently repeated. In some cases top-milk mixtures might be indicated, though the infant's tolerance for fat should not be exceeded.

Case 1.—A. C., aged 10 months, admitted into my service in the children's ward of the Michael Reese Hospital, July 27, 1912. The baby was one of twins. She was breast-fed for the first month; then she was put on milk and Mellin's food until 4 months old, when she began to vomit her feedings. The mother was advised to try strained oatmeal gruels without milk. She instituted this plan of feeding until the present time. During the past week the patient has had diarrhea; first three or four yellow slimy stools and after the administration of calomel numerous green stools. She has not vomited, is very restless, cries a great deal and sleeps poorly. There is no history of previous illness.

Patient has six brothers and sisters, all living and well. When she was admitted into the hospital it was noticed that she appeared pasty, somewhat swollen. Her face was puffed and on palpation the surface of her body gave a doughy sensation. The eyes showed cloudiness of both corneae. On the left eye over the conjunctiva a large vesicle occurred. In the right eye several small vesicles were present. Marked photophobia, increased lacrimation and circumcorneal injection was noted. There was no purulent discharge. The bony thorax showed the presence of a well-marked rosary and a flaring of the costal arches. The abdomen was somewhat depressed. There appeared to be a loss of subcutaneous adipose tissue and the skin was harsh and dry. The abdomen was covered with numerous macular discolored areas varying in size from a pin point to a small bean, many tending to coalesce, showing a distinct bluish color—a diffuse purpura hemorrhagica. The photophobia tended to increase, and the cloudiness of the cornea, particularly of the right eye, was more distinct. There was marked keratitis in both eyes. During the first few days the infant's temperature was rather high, reaching 104 F. The leukocyte count was 33,500, with 82 per cent. neutrophils, six small mononuclears, eight large mononuclears, four eosinophils, and hemoglobin 62. On admission the child was greatly prostrated, rapid pulse and slightly accelerated respiration.

The infant at first was given a tea diet for twelve hours; then was placed on dram doses of breast-milk every hour and when an improvement in the appearance of the child was noted 6 drams of breast-milk were given every two hours. On the fifth day after admission the child was given 6 drams of skim-milk and 6 drams of breast-milk with 2 grains of citrate of soda, and 4 ounces of water every three hours. The baby lost 4 ounces in weight during the first several days of this treatment. On the fourteenth day after admission to the hospital the breast-milk and the skim-milk were increased to 2 ounces of each and 2 per cent. of *Nährzucker* was added to the diet. On the thirty-third day after admission she had shown considerable improvement and meat broths with vegetables were added to the diet. At the same time mashed carrots and baked potato were given without bad results.

An abscess appeared on the back after the child had been in the hospital for six weeks, which required incision and drainage. Later on a somewhat generalized furunculosis appeared, which seemed to improve with treatment by staphylococcus vaccine. One month after admission the patient showed an abundance of pus in the urine with elevation of temperature and considerable constitutional disturbance. The corneal opacity had entirely disappeared. The baby was playful, happy and active. She enjoyed her food, was gaining in weight, the purpuric spots on the abdomen slowly though constantly showed marked tendency to fade.

The child was discharged on Dec. 23, 1912, after fifty-nine days of treatment, showing a marked improvement.

Case 2.—This infant, also one of twins, from the service of Dr. Julius Hess, weighed 7 pounds at birth. It was three months old on admission to the hospital. The first baby was breast-fed exclusively, while the second of the twins, which was the stronger at birth was breast-fed for the first two weeks, then given half milk and half oatmeal water for three weeks. Milk-sugar was added at the end of this time and the baby showed symptoms of indigestion and diarrhea. As it seemed quite impossible for the baby to take milk it was put back on the oatmeal water and this was continued for several weeks. After some time the bowel movements became thin and sour and frequent and she vomited very much. Emaciation was progressive and the baby weighed 6 pounds 2 ounces when she was three months old. The skin was dry and inelastic; the normal turgor was absent; the baby was atrophic and had a senile appearance. The breathing was rapid and shallow and the condition seemed desperate. The infant was placed on small doses of breast-milk and three weeks afterward was beginning to gain in weight and from this time on she made a rapid and complete recovery.

104 South Michigan Avenue.

ABSTRACT OF DISCUSSION

Dr. F. P. Gengenbach, Denver: I wish to cite a case that came to my attention about two years ago. The patient was a baby about 7 months old with acute gastro-intestinal disturbance. The doctor took the baby off its food and put it on barley-water. Unfortunately for the baby, the doctor became ill and forgot about it, and the mother left the baby on barley-water—nothing else—for two weeks. I found the baby with all the appearances of a child with marked nephritis. Its face was puffed up and the whole body edematous. The case might have been called one of acute *Mehlnährschadung*. Things were not so desperate as they looked, however. I took the baby off the barley-water, gave it a weak milk modification and it promptly recovered.

Dr. F. W. Schlutz, Minneapolis: A case of this kind has recently come under my care. The most pronounced symptom was the hypertonic contraction of the muscles of the extremities. Both hands were clenched and the nails buried deeply in the palms. This condition had existed for weeks. The child, for several months, had received only oatmeal or barley-water seasoned with salt. The extremities presented marked edema. Another feature in this case was the condition of the sensorium. The child gave the impression of idiocy. The sensorium was always clouded. The mother of the child had a 4-month-old baby which she was nursing. This fact made possible the therapy carried out in this case. The nursing baby was put on mixed feeding—part breast and part buttermilk. The sick child was given breast-milk, expressed from the mother, with supplementary feeding of buttermilk. The physical condition of the child has improved markedly. The mental condition and the hypertonicity remain unchanged. It will be interesting to see whether these conditions will improve or whether they are permanent changes.

Dr. Julius Hess, Chicago: I believe that there is an important lesson to be learned from these cases. Either we do not see many of them, or we lay the death to something else. I believe the latter is true. It is a common practice to tell the mother, if the baby has diarrhea, to put it on barley-water or rice-water, but I believe we are a little indifferent about warning as to the dangers of this, especially of its long continued and repeated use as an exclusive diet. Most mothers keep the baby on the cereal waters but a short time, but as soon as the baby has a loose bowel they repeat it. With each withdrawal of food and placing on cereal water exclusively, the convalescence is slower. I believe the lowered resistance, especially to general infection, is marked. It is our duty to warn against the complete withdrawal of food over any continued period.

Dr. L. Duncan Bulkley, New York: I do not know how many of you remember a paper I read many years ago before this section about a certain preparation for infant feeding which I called wheat jelly. I have used this for over twenty years in hundreds of cases. My opinion about all this trouble is that starch is generally not cooked enough. I use crushed wheat—the whole wheat. My directions are to take a teacupful of whole wheat, put it in cold water in the afternoon at 3 o'clock and boil for three hours. Then set it aside in a china vessel. Those of you who have eaten wheat which has been cooked over night know that it is sweet; a certain amount of diastatic fermentation has taken place. In the morning more water is stirred into it to make it quite soft, and it is boiled three hours more. It is then rubbed through a fine sieve with the bowl of a spoon. By scraping off what is under the sieve we have a jelly-like mass representing all the wheat, except the external silex coat.

Two or three teaspoonfuls of this wheat are put into the milk at each feeding. It passes readily through the nipple. In this manner we have extracted all the components from the wheat, including the nitrogen from the germ and the phosphates from the outer coating; we have then an entire wheat product, which nature intended we should take. For twenty years and more I have never used barley or any of the prepared foods, as I find that the wheat jelly is a perfect nutrient. I think that this is worth trying for the summer diarrheas.

THE TREATMENT OF HEMORRHAGIC DISORDERS *

THOMAS B. COOLEY, M.D.
DETROIT

Within the past few years, chiefly because of better knowledge of the physiology of the blood, much new light has been thrown on a group of diseases which have always aroused great interest, but whose pathology has been obscure, and whose treatment has been exceedingly unsatisfactory.

Of these diseases, the most important clinical feature of which is a tendency to uncontrollable hemorrhage, the most important to pediatrics are the so-called melena neonatorum, the purpuras and hemophilia; the last being, of course, equally evident in later life. Etiologically, we are still in the dark regarding all of them. Hemophilia shows two very important differences from the others. It is a permanent, not a temporary condition, and it is not characterized by spontaneous bleeding or oozing from the vessels, but merely by failure of the ordinary method by which a break in the vessel wall is sealed after it occurs. In purpura, in a number of the various conditions which are grouped under the vague term "melena," and in the hemorrhage of septicemia, which seem to be closely related, there is, on the other hand, a very pronounced tendency to spontaneous leakage from the vessels, as well as the failure of the blood-clot to form sufficiently to put a stop to this. In these diseases, moreover, if the outcome is not fatal, the hemorrhagic tendency usually entirely disappears, and the patients become wholly normal in this respect. These differences seem to me to be highly important in formulating anything like a satisfactory theory of the probable causes of the conditions and the rationale of treatment. It is wholly impossible, within the limits of a short paper, to analyze the voluminous literature of the past few years regarding the pathogenesis of hemorrhagic diseases. I shall try merely to present briefly the points important to my argument.

It has long been noted that in all these conditions the blood was often slow to clot, the clot when formed frequently was abnormally soft, and the failure of the clot properly to seal the vessel was generally believed to be the reason for the continuance of the hemorrhage. As the physiology of clot formation became better understood, a lack in the blood of some one of the essential elements was assumed to be the cause of this failure. Calcium, fibrinogen and prothrombin all being essential to clotting, a deficiency of any one of them might delay clot formation, while an excess of antithrombin would prevent thrombin formation even in the presence of sufficient prothrombin. The existence of thrombokinase is still in doubt, but there are those who believe that its absence will account for some cases. Definite proof of a deficiency of any of these elements was long lacking. Duke[1] in 1910 thought that he had shown a relation between a low platelet count and purpura and has emphasized this idea in further publications. The blood low in platelets is said to clot in normal time, but the clot does not contract sufficiently to seal the vessel. Schloss[2] found thrombin lacking in some cases of melena. Whipple[3] has found antithrombin present in septicemia, prothrombin absent melena, and fibrinogen deficient in hepatic cirrhosis. He suggests the possibility of classifying the hemorrhagic diseases according to which element is lacking. Calcium has not, I believe, been proved to be absent in any case of hemorrhage, though it is probable that the abnormal coagulability in jaundice may be due to relative lime deficiency. Sahli's[4] studies of hemophilic blood were interpreted as showing lack of thrombokinase, while Addis[5] thinks that he has shown defective activation of prothrombin.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

It seems proper to believe, in view of this work, that temporary or permanent absence of some one of the clot elements is the usual cause of the persistence of hemorrhage in these conditions, and that different elements fail in different conditions, if not in different cases of the same condition. Whether or not we are also to believe with Whipple and others, that this is also the cause of the inception of hemorrhage, abandoning the older idea of some unexplained fault of the vessel walls, is another question. As Schloss has said, it seems impossible that a lack of any one of the clot elements should in itself account for a leakage of blood through a normal vessel wall; moreover, if this were the case, spontaneous hemorrhages should be common in hemophilia, where the blood abnormality is permanent. In spite of the lack of any definite proof, it seems to me that we must assume a diseased condition of the vessel wall as well as of the blood, except perhaps in those cases of the melena group where ulcers, thrombi or extreme congestion are present.

In accord with this idea of the failure of clotting as the cause of the persistence of the hemorrhage, treatment intended to supply the lacking element has very rapidly come into favor. The only inorganic blood-clotting element, lime, has been tried, but with little success. The other elements being all peculiar to the blood, blood preparations in one form or another are now being widely used in all of these diseases, and, if one were to judge merely by the reported cases, with almost invariable success. Normal animal serum was first used, chiefly that of the horse, sometimes that of other animals; the serums of the dog, bullock and goat being least in favor, because of toxic properties. Antitoxin has a number of times served in a pinch.

Lately, apparently owing chiefly to Welch's[6] very favorable reports, though he was not the first to suggest it, human serum has been used and highly praised by various American writers. Schloss injected whole human blood subcutaneously, believing it possibly advantageous to have all the blood constituents present. Very recently, precipitated, dried and powdered horse-serum, said to contain all the essentials to clot formation in at least normal concentration, and less subject to deterioration than in the liquid form, is being urged. Clowes[7] believes this to be more efficacious than fresh serum. Transfusion of whole blood has so far been reserved almost exclusively for use as a last resort in really exsanguinated patients, because, no doubt, of the difficulty attending ordinary methods of performing it.

Two things are very striking about the reports of successful treatment with blood or serum. One is the promptness with which the hemorrhage ceases, and the other, the relatively small amount used. Schloss, for instance, got prompt recovery after a single injection of 5 c.c. of whole blood, and most of the recoveries have been after injections of not more than 20 or 30 c.c. in all. Clowes reports the necessity of large amounts in one case of melena.

It is wholly impossible, at present, to gain any really accurate idea of the value of serum or blood injections or of the relative value of the different preparations. The tendency to report success rather than failure is well known, and many of the reports to be found are of single instances of success with any one of the preparations.

The reports of series of cases deal chiefly with melena. Swift and Green,[8] using rabbit-serum, had rather less success, apparently, than in the cases which were treated with gelatin and which they report in the same article. Schloss had much better results with human serum and whole blood, the whole blood being apparently more effective and in smaller quantities. Welch had remarkable results with human serum. Clowes' article deals with a series of very diverse conditions treated with solutions of serum powder. He seems to assume that there was lack of thrombin in all of these cases, though in some of them there seems to be no reason, except the persistence of hemorrhage, to suppose that a deficiency existed of any of the clot elements. In gastric ulcer and pulmonary tuberculosis, for instance, there is no need to assume failure of clotting in order to account for severe hemorrhage, though the cessation after serum injection might be held to prove that the coagulating mechanism was at fault.

I have found no reports of series of cases of hemophilia, but the isolated cases and small groups show almost invariable success with injections of any form of serum, or local applications of fresh or powdered serum to the bleeding spot. Prophylactic injections before operation are reported as successful by Clowes.

On the whole, the evidence from the literature seems distinctly in favor of human over animal serum, except for Clowes' series. This serum powder has only lately been available for extended trial, so that reports from other investigators are not yet at hand. My own experience with it in melena has been by no means so favorable as Clowes'. I have used it in two cases apparently with no effect whatever. In the first, which I have reported, the patient was saved by transfusion after serum powder and fresh human serum had apparently failed to check the hemorrhage. Clowes' criticism (private communication), in this case that I did not use enough serum, may be justified. The second case was seen in the evening, shortly after the onset of hemorrhage, which was not at that time profuse. The baby received during the night 20 c.c. of serum powder solution and 20 c.c. of the father's serum, and died within an hour after the last injection of human serum, with symptoms of intrathoracic hemorrhage. Clowes seems not to believe that there is danger of anaphylaxis from the use of horse-serum. While I admit that this danger is slight, it seems to me sufficient to make human serum preferable, inasmuch as it seems to be at least fully as efficient.

[8] Swift and Green: Boston Med. and Surg. Jour., 1911, clxiv, 454.

There are at hand very few statistics containing the results of transfusion. Considering the very grave condition in almost every case in which it has been resorted to, it seems to me to have been more efficacious than any of the other methods. Several patients have been cured by it after serum injections had failed to check the hemorrhage.

Curiously little has been said by any of the writers concerning the probable action of serum or blood in checking hemorrhage. It seems to be taken as a matter of course that the blood preparation acts by supplying the deficient clot-element, whatever it may be. The correctness of this assumption seems to me very doubtful. None of the clot elements are supposed to have a ferment action except the purely hypothetical thrombokinase. Definite quantities of each of the others go into the reaction, and it is difficult to suppose that the injection of relatively small amounts of serum or blood can possibly make up for any serious deficiency of any of them. It seems to me impossible that Duke can be right in supposing that the enormous increase in the platelet count reported by him after transfusion was the result simply of the addition of the platelets of the transfused blood. The amount of blood transferred by ordinary transfusion, which cannot be definitely measured, is certainly too small for this to be true. Admitting the existence and importance of thrombokinase, and assuming it to be present in any quantity in the injected serum, it might explain the cessation of hemorrhage in cases where thrombin formation is insufficient.

Another thing not satisfactorily explained by the idea of injecting a lacking clot element is that the patient is so often definitely cured. Not only is the existing hemorrhage stopped, but the tendency to bleeding disappears, and the blood soon shows normal coagulability. It is, I think, more reasonable to suppose that this effect is due to some stimulant action of the normal serum or blood on the blood-forming tissues or in the vessels. Esch has suggested that the bone-marrow is stimulated to the formation of thrombokinase. As we have no reports of the successful use of serum in cases in which any other element than thrombin was definitely proved to be lacking, this explanation might be correct. In the absence of more exact information, I prefer to suggest that the blood-forming tissues react to the stimulus of normal serum (or blood), by the formation of normal blood, and that possibly there is a reaction between normal blood and the vessel-walls, lacking in certain abnormal blood-states, which explains the complete cessation of hemorrhage. This hypothesis is vague, but something of the kind seems necessary to fit all the facts.

Such an assumption would give a reason for the apparent relative values of treatment by animal serum, human serum, whole human blood by subcutaneous injection, and whole blood by transfusion, which would not at all apply if the end to be obtained was merely to supply a lacking clot-element. Human tissues would naturally react better to human than to animal serum, to whole blood than to serum, and probably to whole blood put directly into a vessel than to the same blood injected subcutaneously, where it must partially disintegrate. I make this suggestion for what it is worth, admitting it to be pure theory, and incapable of demonstration with our present knowledge.

All things considered, whatever theory one may adopt, it would certainly seem, so long as we cannot determine at the bedside just what blood element may be needed, that there should be a wider use of direct transfusion in serious hemorrhage, because of its supplying for immediate availability all of the factors likely to be concerned; and that the transfusion should be early, rather than as a last resort after everything else has failed. The technical skill required has heretofore stood in the way of this, but recently there has been more than one suggestion of simple methods for accomplishing the operation. Crile's method is an improvement over direct suture or the older cannula methods, but is not readily applicable to the small veins of babies. Vaughan and myself[9] have described a method used by us which required no special apparatus, and which we have found to be really as easy as any intravenous injection. It consists simply in drawing blood from the donor's vein into a glass syringe and injecting it rapidly into the vein of the recipient. A small amount of physiologic salt-solution is drawn into the syringe before and after the blood, to prevent clots forming in the needle or the vein. The only requisite for success, apparently, is to have everything so prepared that one may work fast and keep within the time-limit of coagulation. We have ourselves practiced the method once since our report, in a case of septicemia, and Rowland (private report), used it without difficulty and with remarkable results in a case of severe melena with bleeding from the cord, mouth, and numerous areas in the subcutaneous tissues. Pope has recently described a method used by him on laboratory animals which he says is very easy. Freund, working with the anemias, has recently developed an improvement (unpublished), on our syringe method, by which he was able easily to transfuse 140 c.c. in a few minutes. The apparatus consists of a syringe connected by a Y and short rubber tubes, with two needles. At the branching of the Y is a two-way valve, and connected with the proximal branch of the Y is a tube, with stopcock, for salt solution. The needles are inserted into the veins of the donor and recipient and connected with the syringe. As the blood is drawn from the donor's veins about 10 per cent. of salt solution is allowed to mix with it. Dilution in this way with about 10 per cent. of saline solution prolongs the coagulative time considerably. The valve is turned and the diluted blood is injected into the patient. This procedure may be repeated, 20 c.c. at a time, almost indefinitely, with no apparent danger. Either of these syringe methods is as simple, and probably as safe as ordinary intravenous injection, and they have the additional advantage over ordinary transfusion methods of being quicker, as the positive suction and pressure of the syringe make it possible to transfer the blood much more rapidly. Moreover, it is possible, working by either of these methods, to interrupt the procedure at any time, and renew it at pleasure. With former methods, the difficulty of the operation and the sacrifice of the vessels which is involved, required one, in order to be sure of going far enough, to carry it often to very tedious lengths. The amount really necessary to be injected sometimes proves to be very small. Rowland, for instance, could see almost immediate results from 8 c.c., and was not obliged to use more, but with any other method he would have felt compelled to go a good deal further before breaking the connection between the vessels.

---

[9] Cooley, Thomas B., and Vaughan, Walter: A Simple Method of Blood-Transfusion, THE JOURNAL A. M. A., Feb. 8, 1913, p. 435.

It seems probable, from a perusal of current medical literature, that human serum or blood is to be used, or at least extensively experimented with, in the treatment of a variety of conditions aside from those I have spoken of. Already they are being tried in the anemias, and in pediatrics there are favorable reports of human serum in grave nutritional disturbances. In all of these, it is possible that human blood injected intravenously might be of more use than serum. The purpose of this paper is to urge that simplified transfusion be given a more extended trial, especially in melena, which is one of the most serious conditions with which we have to deal; and that it be used as a first rather than a last resort.

CONCLUSIONS

1. Blood therapy of some kind is the best remedy we have for hemorrhagic conditions.
2. In hemophilia blood-serum seems to have a specific action so far as checking the hemorrhage is concerned. It may be used as a prophylactic measure, as well as to stop existing hemorrhage. Fresh human serum is probably to be preferred.
3. In purpura, melena, and other toxic conditions, in which various blood elements have been shown to be lacking, none of the serums are always effective, and there are good theoretical and clinical reasons for believing that whole blood should be preferred, not only to stop hemorrhage, but for a possible curative effect on the underlying disease condition.
4. Transfusion is not really a difficult procedure. It is deserving of extended trial—not as a last resort, but as the first treatment in any of the hemorrhagic diseases of toxic nature.

Note.—Since this paper was read, Freund has published a description of this method (*Jour. Mich. State Med. Soc.*, September, 1913, xii, 459).

Fine Arts Building.

ABSTRACT OF DISCUSSION

Dr. V. D. Lespinasse, Chicago: I have treated ten cases of hemorrhagic disease of the new-born by direct transfusion of blood. Some of these cases had been treated previously with various serums. Among the ten cases there were but two deaths; both patients were weak syphilitic babies. The cases were of all grades of severity from a comparatively mild to a very severe form. The most desperate case was that of a child born on Thursday at midnight. It started to bleed from the bowels on Saturday at 6 p. m. While being taken to the hospital the child vomited blood. It was transfused at 9 p. m., three hours after the discovery of the hemorrhage. While I was dissecting out the vein, the pulse stopped and the heart was neither audible nor palpable. Fifteen seconds after the blood began to flow into the internal jugular vein, the heart began to beat and the child recovered. The child was in the hospital one week and gained an ounce a day in weight. It is now alive and well. In transfusing these cases, I do not know how much blood is put into the vascular system. I transfuse until the children are red as in scarlet fever. When the operation is begun the babies are pale. If we allow the blood to flow in too rapidly the baby becomes bluish. If this occurs, the flow of blood should be stopped temporarily. When the baby's skin is a decided red, the anastomosis between the two vessels is cut and the vessels ligated. The effect on the babies is immediate and prompt. The hemorrhage stops at once and does not recur. I should like to emphasize the point that Dr. Cooley made, that transfusion is the best treatment for hemorrhagic disease of the new-born, and should be used early. I should also like to emphasize the fact that it is never too late to save a baby by transfusion, so long as there is a flutter in the heart; even if the heart has stopped for a few minutes, there is a chance to save the baby by transfusion properly done.

Dr. H. M. McClanahan, Omaha: The remarks that I have to make are in the interest of the doctor in the small town who does not have modern facilities. I am glad that Dr. Cooley made the distinction between hemorrhage in the new-born and hemophilia. By hemorrhage in the new-born I believe he means spontaneous, not traumatic, hemorrhage.

Within the past year I have had five cases of hemorrhage in the new-born. In these cases I have recommended the use of antidiphtheritic serum, using a serum with a low number of antibodies. I have personal knowledge of three cases in which the hemorrhage was evidently sufficient to cause death, although I do not believe that these infants die from actual loss of blood, but from that condition which causes the loss of blood, and I believe that antidiphtheritic serum is an excellent remedy. It is not so good as transfusion, but in the small towns it is a good substitute.

Dr. Julius Hess, Chicago: The thing which has interested me most is the evolution of the medication in the hemorrhagic conditions. At first most of us used diphtheria serum without further thought. Following that a normal horse-serum was put on the market and we used that. Then came anaphylaxis. Then we used rabbit's blood, and eventually adopted the simple method of drawing a small quantity of a 10 per cent. sodium citrate solution into the barrel of the syringe, taking from 10 to 15 c.c. of blood from the vein of the mother and injecting the mixture directly into the vein of the child. Theoretically there are some reasons why we should not use sodium citrate. The results with this are as good as with horse-serum, and its use has obviated the dangers of anaphylaxis.

Dr. Ogden M. Edwards, Jr., Pittsburgh, Pa.: This is a serious condition which occurs in children at the beginning of their lives. The treatment at present is not satisfactory, as Dr. Cooley says. The use of serum and of some of the preparations of blood is the best treatment we have to-day. We shall never get the proper treatment for all of these cases until the etiology of these conditions has been discovered. We probably have a right to believe that these are different conditions, having one thing in common, spontaneous hemorrhages, and that there are different causes for the hemorrhages. If we could find these different causes we should get at the treatment better. Some hemorrhages may be due to infection, as has been suggested, but whether or not infection is the etiologic factor we are unable to say. Some of them are associated with syphilis, but we are not able to say whether or not that is the cause. Certainly we know that some of these children are not syphilitic.

The suggestion by Evarts Graham is interesting; that lack of proper oxidation existing in the mother before the child is born may play a part in the production of these conditions. He has brought about a change in animals experimentally by producing a lack of oxidation in the mother.

The etiology of these conditions is still unknown, however, and the treatment, therefore, will never be on satisfactory grounds until these hemorrhages have been differentiated according to their etiology. Some of the patients recover with serum and blood preparations, and some do not.

Dr. H. Lowenburg, Philadelphia: I should like to report a case of hemophilia in a 2-year-old child. His mother's brother died of uncontrollable hemorrhage following a slight injury, and his own brother succumbed to this same condition. This boy bit his tongue and had been bleeding for two days when I saw him. He was very anemic and restless. He responded promptly to two injections of horse-serum given at 7 p. m. and the following day at about 10 a. m. A point of interest that this particular case illustrates is that probably a permanent cure is not produced, because about five or six months later this boy suffered a slight trauma of the hip, which was followed by extensive ecchymosis. There was no break of the skin, and the ecchymosis was five or six weeks in disappearing.

Dr. C. Brooks, Pittsburgh, Pa.: I have for some time been interested in the technic of transfusion. Almost two years ago I suggested the use of a syringe to transfuse blood in infants. Since I located in Pittsburgh Dr. Edwards has spoken to me about some cases in which transfusion by the union of blood-vessels failed. I suggested that we try to work out some simple methods of transfusion. I am gratified to learn from the discussion here to-day that a good many simple methods have already been used. For instance, Dr. Cooley's method, in which he used a syringe with an ordinary needle and a method of drawing the blood in at one side, and throwing it out from the other with a "Y" shaped connection, is doubtless a good one.

Dr. Edwards and I have a method which we think more certain of success and more easy of use than any method yet discovered.

I think that all physiologists will agree that it is best to use for transfusion the normal blood. That is the least dangerous. Defibrinated or salted blood are departures from the normal. From theoretic considerations, however, the least objectionable salt to use for that purpose would be sodium oxalate. We have performed some experiments on animals, using this salt. It works very well. We draw into the syringe about 0.5 c.c. of a 1.0 per cent. solution of sodium oxalate and then draw the syringe full of blood. When this is done it will not clot. The needles which we have tried on animals are fashioned so that when once inserted they will not come out, neither will they cause laceration of the wall of the vessel.

I think that Dr. Cooley is right—we should not necessarily call in a surgeon to do transfusions. Those living in the country cannot always get a surgeon. They must go ahead and do the simplest transfusion possible. If they employ this syringe method, they will know how much blood they are transfusing. Some surgeons tell me that when they use the more complex methods they are not certain how much they transfuse, or indeed, whether or not they transfuse any blood at all. Apparently the right tendency is toward a simple method and toward the use of a syringe with the trocar cannula needle.

Dr. T. B. Cooley, Detroit: In regard to the blood necessary for transfusion, Dr. Lespinasse has said that in direct anastomosis methods it is advisable to transfuse babies until they are red. In the case reported, the child was practically dead when we started. We used altogether 20 c.c. of blood, with salt solution between the blood injections. We did not carry transfusion anywhere near the point of redness of the child. The child was still pale, but we could see a definite improvement; the pulse was becoming stronger and we felt safe in waiting; we knew that we could transfuse more blood at any time. The child did well. As regards transfusing blood slowly, we used injections of salt solution between the injections of blood. Maybe, if we had put in one blood injection after another, we should have gone too fast.

The point that I was especially anxious to make was that the doctor in the small town can do transfusion with one of these simple methods. It is a thing anybody can do who can dissect out a blood-vessel.

Nobody answered Dr. Hess' question about anaphylaxis. I have been unable to find any reports about anaphylaxis from the use of antitoxin in this way. Those of us who use diphtheria antitoxin extensively know that the proportion of anaphylaxis is slight. When horse-serum has been used in a large number of hemorrhagic cases, we shall probably hear of some cases of anaphylaxis.

There is one thing quite evident in regard to the etiology of nearly all of these conditions—they are the result of toxemia of some kind. Toxemia resulting from lack of oxygen is certainly a possible cause.

I was careful to except hemophilia from the conditions in which one gets a permanent cure.

I do not think that the addition of oxalate to the blood is necessary or desirable to prevent the blood from coagulating. If one can delay coagulation of the blood a little time, that is all that is necessary. If we are sure of our technic we can do this without any other assistance.

Dr. Brooks' needle is much like one which Dr. Vaughan and I made, although we decided that it was not absolutely necessary to have a special needle.

THE NATURE, DIAGNOSIS, PROGNOSIS AND TREATMENT OF GENERAL PARESIS *

CHARLES R. BALL, M.D.
ST. PAUL, MINN.

The honor of having first discovered a relationship between paresis and syphilis belongs to Esmarch and Jessen. These observers in 1857 reported three cases of paresis, the cause of which they attributed to syphilis. Thus a controversy of this subject began which has lasted for more than half a century. The consensus of medical opinion has held that in the great majority of cases syphilis is the chief etiologic factor which causes paresis. Of the opponents of this doctrine Näcke was the most extreme. He considered a neuropathic inheritance as a most important cause and assigned to syphilis an equal importance among other etiologic factors, maintaining that it often furnished the last offense for the development of the disease. It was not until the discovery of the Wassermann reaction and its regular observance in both the blood and spinal fluid of paretics that the doctrine of no syphilis, no paresis, could be said to have found universal acceptance.

Until recently parasyphilis has been regarded as an effect of syphilis, the ashes of a fire which long ago has burnt itself out, the result on the nervous system of a toxin which might be compared to the action of the toxin of diphtheria in diphtheritic paralysis, when the exciting factor, in both instances, had passed away, but the harmful influence still acted in a progressive manner.

A number of reasons may be given why we have so persistently refused to accuse the spirochetes of occupying the chief rôle in the causation of the symptoms of paresis. The apparent absolute inefficiency of antispecific treatment, the fact that the pathology of paresis was said not to be the pathology of syphilis and the failure to discover the spirochetes in the tissues of the central nervous system are the chief reasons. Since the discovery of the Wassermann reaction, however, and its positive finding regularly in paresis, the suspicion has steadily grown that the *Spirochaeta pallida* is actively and directly concerned in paresis. Plaut calls attention to the fact that a paretic behaves with reference to the serum reaction similarly to a syphilitic in the active stages and not as a tertiary luetic without symptoms. This indicates, according to Plaut, a more active participation of the spirochetes in paresis than was formerly thought. He believes that there is a close relationship between the activity of the specific virus and the Wassermann reaction. Nonne says that occasionally the blood of a paretic may give a negative Wassermann and that rarely also all four actions may be negative in tabes. These results usually occur, however, in exceedingly long-standing and chronic cases after the active process and progression of symptoms have long since terminated. This observation of Nonne's would seem to support Plaut's contention.

The fact that active syphilitic processes in the nature of gummata and specific endarteritis are found both in paretics and in tabetics also argues for a close connection between the spirochetes and paresis. Recently E. Meyer[1] has reported a case of syphilitic meningomyelitis occurring in a paretic. The active syphilitic process in the cord was healed by antispecific treatment, as the post-mortem later demonstrated.

[1] Meyer, E.: Progressive Paralyse kombiniert mit Meningo-Myelitis marginalis, Arch. f. Psychiat. u. Nervenkrankh., L, No. 1, p. 245.

The pathology has been one of the strong arguments against regarding paresis as a late syphilis. On this question Spielmeyer[2] says that, although the pathology of paresis is a characteristic one and differs materially from the pathology of cerebral lues with which we are familiar, we cannot say that it is no longer a syphilitic process. He argues that as we are unable to say with certainty what pathologically belongs to syphilis, therefore we surely are not justified in saying that certain processes are non-specific in character. Primary parenchymatous degenerations can just as easily be caused by syphilis as specific cellular infiltrations. Nissl takes a somewhat similar position. Thus according to these observers we are not able to state positively that the pathology of paresis may not also be the pathology of syphilis.

The inefficiency of antispecific treatment has been another important reason why the diseased processes of paresis have been regarded as of a different nature from those of lues. The tendency to exclude syphilis when a disease failed to respond to antispecific therapy has been too general. We have known for some time that certain specific processes are often refractory to treatment. Nonne[3] says that the general medical opinion in regard to the success of antispecific therapy is too optimistic. Spielmeyer suggests as an explanation of the failure of antispecific therapy the impermeability of the meninges. A large number of experiments have been made and from these it has been demonstrated that mercury and iodin, under normal conditions, are unable to penetrate the meninges. The difficulty exists in paresis and tabes. This author says that perhaps the inadequateness of our present methods of treatment in not being able to pass through the meninges may be largely responsible for the failure of this treatment in paresis.

Recently Noguchi[4] has examined the brains of a large number of paretics. Out of 200 examined he has been able to find the spirochete in forty-eight, and in the spinal cord of one tabetic out of twelve examined. He found the spirochetes more numerous and more frequent in the brain cortex than in the white substance. They were distributed between the nerve-cells and the neurogliar tissue. In some instances the parasites were found in the nerve-cells. In those cells containing the spirochetes evidences of degeneration in the form of distortion and swelling, as well as the complete dissolution of both the nucleus and the cell-processes, were discovered. Noguchi, in connection with the report of his examination, says that the pathogenesis of paresis was never entirely free from objection. Since, however, the causal factor of syphilis has been found in the pathologic changes, one may well assume that these changes are directly due to the *pallida*. He characterizes the brain changes as a chronic parenchymatous encephalitis produced by the invading spirochetes. He suggests that the fact that treatment thus far has proved so futile may be explained by the circumstance that the parasites lie in the nervous parenchyma away from the blood-vessels and are inaccessible to the medication. Confirmation of Noguchi's discovery by other observers is all that is lacking in order to bring about a complete reconstruction of our former ideas concerning the nature of metasyphilis. This must all deeply affect the whole subject of paresis. It increases very much the importance of diagnosis and particularly of an early diagnosis. Kraepelin[5] says that it is often very difficult to determine the actual beginning of the affection. A number of years may intervene between the observance of such symptoms as transient attacks of double vision, dizziness, temporary aphasia and unconsciousness and the real development of the paresis. He reports two cases in which there was an interval of six years between the observance of such symptoms and the beginning of the paresis. I can recall one case which came under my observation with symptoms of dizziness, loss of the pupil light-reaction and occasional attacks of unconsciousness in a patient with a luetic history four or five years before sufficient mental change had occurred to make it necessary for the patient to give up his regular work. When should the diagnosis have been made in this case, at the time of the first attack of unconsciousness or four years later when the paresis was well advanced? It is interesting and, in the light of our recent knowledge, very important to know how far back we may date the real origin of the paresis with a history of such symptoms as those mentioned.

Another interesting and practical question is, if this case had been regarded as paresis when the first symptoms appeared, would active and persistent antispecific treatment, such, for instance, as the chronic intermittent, or the intensive along the lines proposed by Dreyfus and Gennerich, have exercised a restraining and beneficial influence on the later course? It must be acknowledged that the only difference between tabes and paresis exists in the location of the pathologic process. Because of the larger brain-area and, therefore, greater capacity for compensation, the prognosis for the brain-process ought to be better than for the one in the cord. In regard to the influence of antispecific treatment in tabes, Nonne says that for many years he has had a large number of cases of beginning tabes under observation in which the disease had apparently been brought to a standstill by means of regular courses of inunctions. Because of the peculiar anatomic structure of the cord, beginning lesions there would naturally cause much earlier significant symptoms than corresponding processes in the brain. On account of the so-called silent areas in the brain, extensive lesions may exist without manifesting any symptoms. Failure to recognize the nature of early symptoms before the diseased processes have become too extensive may be another explanation why antisyphilitic treatment has proved so ineffectual in paresis.

During the past two years it has been my practice to make a Wassermann examination of the blood in every one of my hospital patients. If the Wassermann was found to be positive and the patient exhibited any nervous symptoms, no matter how slight in character, I then made a lumbar puncture and tested the three reactions. With positive findings the interpretation of even slight psychic symptoms becomes easier. With the modern diagnostic methods a much earlier diagnosis of paresis becomes possible, and the importance of this, in the light of recent additions to our knowledge, is greatly increased.

[5] Kraepelin: Psychiatrie: Die Dementia paralytica Verlauf; Ausgang, Ed. 8, ii.

Nonne, in his book, "Syphilis and the Nervous System," says that a genuine paresis was formerly considered incurable, but that this opinion at the present time cannot be unqualifiedly maintained. Schüle reports a case of undoubted paresis with recovery after an attack of double pneumonia. The patient remained well twenty years. Many other similar cases have been reported. The tendency among medical men to give an absolutely bad prognosis in paresis as soon as the diagnosis is made has been too general. It has been estimated that 10 per cent. of all cases undergo remissions of variable duration, and from 0.5 to 1 per cent. complete and long-continued remission. I remember that several years ago, after treating a case of paresis for a number of months, I gave a bad prognosis to the family and insisted that the patient should be sent to a state institution. Under osteopathic treatment in the course of six weeks the patient so far recovered that he was able to return to work. His remission lasted just about a year. Such remissions are not uncommon and they may come at any time. In this connection the case reported by Tuezek is worthy of mention. The patient, in 1876, when 38 years old, manifested typical symptoms of paresis, which in 1878 disappeared. In 1883 he developed tabes without any psychic symptoms, which gradually progressed. In 1898, twenty years after the beginning of his disease, he again exhibited symptoms of mental confusion and excitement along with mental enfeeblement, which two years later caused his death. According to Nissl, who made the necropsy, the pathology of the cortex was that of paresis. This case illustrates well the truth of the old German medical *Sprichwort,* "die Syphilis stirbt nicht, sie schläft nur." In making a prognosis in paresis one should always keep in mind the possibility of remissions.

During the last few years considerable effort has been made to find a suitable treatment for paresis. It has been recognized for a long time that fevers, infections and suppurations, such as pneumonia and erysipelas, often exercise a most favorable influence on the affection. There are many observations in which the disease has been brought to a period of quiescence through such intercurrent affections. According to Metchnikoff the important factor in exerting this beneficial influence is the leukocytosis caused by infections of this kind. Wagner's tuberculin treatment, the injections of mixed cultures of dead bacilli and sodium nucleinate, first suggested by Donath[6] of Budapest, were proposed for the purpose of artificially creating this leukocytosis. For two years I have been using injections of sodium nucleinate in cases of paresis under my care. The sodium nucleinate was given in the following manner: Two and one-half gm. of the drug were dissolved in 100 c.c. of normal salt solution made from distilled water and sterilized. The injections were administered weekly. Forty c.c. were given at the first injection and the quantity was increased each week by 20 c.c. until 100 c.c. had been injected. Then the weekly dose was further increased by adding 0.5 gm. of the sodium nucleinate to the solution until the maximum dose of 5 gm. was reached. All of the injections were made into the muscles of the nates. In the eight cases so treated, the four reactions were taken at the beginning of the treatment in each case and then again at various intervals during its course. A leukocyte count was also made before and after the injections. At different periods during the treatment an intravenous injection of salvarsan was alternated each week with the sodium nucleinate. The influence of the treatment on the four reactions was somewhat irregular and uncertain and did not always correspond with the clinical symptoms of the patient. For instance, in one case after the salvarsan injection the positive Wassermann in the blood became negative while the condition of the patient was growing worse. In general the effect of the treatment was to lessen the intensity of the reactions. The reactions in the spinal fluid were not influenced to so great an extent as was the blood-reaction. In none of the cases did any of the three reactions in the spinal fluid become negative. From one to two hours after the injection the patient usually had a chill, which was sometimes very severe. This was followed by a rise in temperature, the temperature often going as high as 103 and 104 F. Usually the temperature became normal again in from twenty-four to forty-eight hours. The number of leukocytes was always increased after these injections, sometimes being twice the number they were before twenty-four hours after the injection. In two cases rather severe suppuration and abscess formation followed the injections. In one case there was a rise of temperature for two weeks as a result of an abscess. In this case at present there is a complete remission. All of the eight cases were well advanced. Two of the patients in this series of cases manifested no improvement whatever, but grew steadily worse. Two had short remissions, one of a month's duration, the other of four months, complete enough so that they were able to return home and care for themselves, but not able to resume their occupations. Two patients who showed considerable improvement are still at home and have been for more than a year. One of these had exceedingly severe symptoms. He was confined absolutely to bed, frequently had involuntary urination and stools, had to be fed by tube and did not speak for several months. While in the hospital he developed severe decubitus. This patient received three salvarsan and twenty sodium nucleinate injections. His remission came rather suddenly. One day he simply waked up—like Rip Van Winkle—and began to talk and manifest an interest in things around him. From being an animal that was just alive, he became something of a human being, clean in his habits, and able to make his own toilet and to go down town and to church alone. His mind was free from delusions, but somewhat enfeebled. A recent letter from his wife states that he is not so well and she fears that he will have to be placed in the hospital again. The other patient received twenty-four injections of sodium nucleinate, after which he returned home in very fair condition. He remained quite well for six months, then suddenly had a severe attack of convulsions, following which he lost his speech entirely. He was returned to the hospital and this time received three salvarsan and eight sodium nucleinate injections of 5 gm. each, the last injection being given in December, 1912. An inquiry, May 1, regarding his condition, elicited the information that he had not been so well mentally and physically for years as he is at present. Of the eight patients treated, two are dead, two are in one of the state institutions and four are still at home. Of these four, the mental condition of two is that of a rather moderate simple dementia. The mental and physical health of the other two is excellent.

This treatment, according to the results which I have obtained, cannot be said to be a great success. It seems, however, to have exercised in varying degree a favorable influence in all the cases with the exception of two. Since the discovery of the Wassermann we have been saying no syphilis, no paresis. We are now able, since the finding of the spirochetes in the tissues of the brain and spinal cord, to go a step farther and say, no spirochetes, no paresis.

---

[6] Donath: Salvarsan in der Behandlung der syphilischen und metasyphilitischen Erkrankung des Nervensystems und dessen kombinierte Anwendung, München. med. Wchnschr., Oct. 22, 1912, Seite 2342

These recent contributions to the subject of metasyphilis have taught us especially two things; first, the nature and location of the enemy; second, the great importance of an early diagnosis, if we wish to have a reasonable hope of destroying him.

Lowry Building.

ABSTRACT OF DISCUSSION

Dr. C. Eugene Riggs, St. Paul: The discovery of the *Spirochaeta pallida* in the brain of the paretic has been the signal for the passing of parasyphilis. There is not the slightest question, I believe, but that paresis is nothing more nor less than a phase of syphilis due to the direct action of the spirochete. I do not mean to convey the idea, however, that the pathologic process in syphilis is the same as that in paresis. In syphilis we have endarteritis, gumma and meningitis; in paresis we have degeneration of the neuron tracts of the spinal cord and of the brain. Why in the one instance we have a degenerative process and in the other a syphilogenous process is a question hard to explain. Possibly the personal equation has something to do with it, or a special toxicity of the spirochetes. Mott cites an instance in which one woman infected five men and every one of those men had paresis. As Dr. Ball has said, we are dealing with a syphilitic process, with the direct influence of the *Spirochaeta pallida* on the nervous system. This gives us a reasonable basis for the use of salvarsan in these cases.

In referring to the early stages of paresis, in which we have vertigo and epileptiform and apoplectiform attacks, Dr. Ball asks whether these symptoms indicate paresis or nervous syphilis. This is a question. The indication is certain, however, for the use of the appropriate remedy in a positive, definite way.

Dr. Ball speaks of a remission of twenty years in one case. There are instances reported of even longer remissions. In referring to the question of recovery he was careful in choosing his words. I think that this is extremely questionable, because if a really degenerative process once takes place, the degenerated tissue cannot be repaired.

Dr. S. S. Glasscock, Kansas City, Kan.: There are undoubtedly some symptoms of beginning paresis that we have overlooked. In the future we shall be able, though these symptoms be ever so insignificant, to make an early diagnosis of paresis, and, by the use of salvarsan, or some other remedy to be developed later on, to treat these cases at a time when we can cure them. I am inclined to think that this knowledge will stimulate among men who have had syphilis the idea that just as soon as they have any nervous manifestations they should see a man competent to make the diagnosis. Possibly, moreover, if they have not the symptoms of the disease, and these examinations are made, we may be able by the use of salvarsan to eliminate from the system the spirochete, by that means ultimately eliminating locomotor ataxia and paresis.

It would be well for us to consider in regard to salvarsan whether or not arsenic, even though it be in a non-toxic form, given in large doses or administered repeatedly in these cases of syphilis, may not ultimately (when a period of years has passed and paresis or locomotor ataxia may be expected to develop) because of its toxic properties have so profound an influence on the nervous system that this will tend to increase the number of cases of paresis and locomotor ataxia instead of decreasing them.

Dr. Lawrence B. P[illegible]sbury, Lincoln, Neb.: We are badly in need of a critical te[illegible] for paresis, especially in the early stages. At present I ha[illegible] to have under my care a man about 65 years of age who came to the hospital with a history of some loss of judgment and some disturbance of emotion. He was jealous of his wife, probably unjustly so, and had a coarse tremor in both hands and a shuffling gait, holding his head forward, but with no definite tendency to propulsion or retropulsion. I felt doubtful as to what I was dealing with until I performed lumbar puncture. Both blood and spinal fluid gave a positive Wassermann reaction. There were 130 cells and increased protein in the fluid. He now has a coarse tremor of about four per second. I suppose that it is a case of paresis. The symptoms began only some six or eight months ago.

Another case was that of a man about 35 years of age whose case I reported to a medical society as typical of paranoid dementia with grandiose delusions pretty well systematized and fairly constant. At that time I could discover no motor symptoms and no physical findings that would lead one to think that he had paresis, but I will admit that I did not puncture him as I should have done. Later on I punctured and found an increase in cells and protein. He now has a slight inequality of the pupils, and his face has flattened out somewhat, with just a mere suggestion of tremor of the facial muscles. He is neat and clean and industrious on the ward.

Another case was that of a man of about 44 years of age who was formerly in the hospital as an undoubted case of manic-depressive insanity in the depressed phase. Twenty years ago he recovered and went away. He had a manic-depressive family history. One of his sisters is in the hospital now and has been there repeatedly. A year before he came to the hospital the last time an internist diagnosed the case as paresis. I thought he was mistaken and so stated to the patient and his friends. The patient had a well-marked hypomania and there was no amnesia that could be discovered. I punctured him at that time and failed to find any increase of cells, but discovered a slight increase of protein, which I disregarded. Later on I punctured him again and found an increase of both cells and protein. The pupils were definitely unequal and unequally responsive to light. They became so rather suddenly, for I had examined him from time to time.

Dr. Albert E. Sterne, Indianapolis: Of course, we all recognize metasyphilis as syphilis, and the condition should be treated as syphilis as early and as vigorously as possible. From some remarks that have been made one would infer that the pathology of paresis is confined to the nervous system. It is chiefly in the nervous system as neurologists see it, but there is scarcely an organ in the body that is not involved. In quite a number of cases, moreover, we find that the condition involves the central nervous system preeminently. These changes we meet in syphilis. I believe that Dr. Riggs remarked that in metasyphilis we have no endarteritis, but to this I do not agree; the secondary changes never could be influenced by the specific treatment so far as we know at the present time. Again, we must consider as coming under this category those cases of paresis which run a clinical course quite different from those that we usually see—those cases in which mental symptoms are manifested, cases of progressive dementia, without the usual euphoria, and without delusions, cases, so to speak, that fade away with almost perfect recognition on the part of the patient that he is sick. Ordinarily by the term "metasyphilis" we designate only cases of paresis, but etiologically it is of importance in other organic psychoses. We are now engaged in a careful examination into the rôle of syphilis in the development of dementia praecox, and I am anticipating a report to be made next week at the meeting in Chicago in which we shall show a positive etiology of syphilis in about one-third of the cases of clinical dementia praecox. It seems to me that in these cases, as in syphilis, we should not neglect the mixed treatment. While we may rely to a considerable degree on salvarsan, we should never neglect the adjuvant treatment which we have always used. This treatment, moreover, especially in paresis, should be given with a great deal of caution, as in my experience the use of salvarsan in these cases is not without danger. In some cases we are now using serosalvarsan, that is, blood-serum plus salvarsan, by intraspinal injection. The results are as yet too problematic to offer more than encouragement to the continuation of this particular type of treatment.

Dr. A. L. Skoog, Kansas City, Mo.: I would question the statement, "No syphilis, no paresis." Possibly reactions have not always shown up positively. There is a certain small percentage of cases in which tests give negative results. Investigators have, as stated, found spirochetes in less than 25 per cent. of cases of paresis. So this can hardly be used as a strong argument. Clinically, however, I believe that all patients with paresis originally suffer directly or indirectly from syphilis.

Dr. George A. Moleen, Denver: I would call attention to a point brought out by Dr. Pilsbury, which seems to have caused some surprise on the part of writers in the foreign journals: the question of isolated syndromes, such as the slow tremor. A case mentioned in the *Revue neurologique* (1911, xxii, 123) was taken to be one of paralysis agitans. In my own experience, a man presented a tremor, confined to the right hand, which could hardly be mistaken for anything but paralysis agitans. He presented little mental disturbance and later developed some mild persecutory ideas, as a result of which he was placed in a general hospital and observed. The tremor has continued and his mental condition has been limited to the persecutory ideas, but within the past two weeks he had a very typical apoplectiform seizure, and I think that there can be no question as to the diagnosis of paresis. The pupillary retardation could be determined only if compared to the reaction of distance, and that is often the case with those symptoms which one might consider as part of the syndrome. I think the pupil should be studied by comparing the rapidity of its reaction to light with that to convergence. Since seeing the case reported in the foreign literature, however, and hearing Dr. Pilsbury speak of it, I am reminded of my own, and thought best to recall the case here as presenting symptoms which sometimes lead to error in the making of a diagnosis of paralysis agitans, when the patient might have beginning paresis as indicated by such an isolated symptom. In my case there had been a positive Wassermann, and besides, there was a distinct, clear history of luetic infection ten years previously, treated for two years by a competent internist.

Dr. E. E. Southard, Cambridge, Mass.: If I am not mistaken we have a similar case at the hospital at present. The patient has the signs in general of paralysis agitans except tremor of the right hand. He had a positive Wassermann reaction, with a total negative finding.

In this connection I might say that at the Psychopathic Hospital statistical data show something that I should like to have explained. We have been making a monthly count of Wassermann reactions up to 31.5 per cent. in a class of cases which are perhaps a little different from the ordinary cases. In the state hospitals of Massachusetts 22 per cent. of positive Wassermanns were found in the total count of the hospitals, including paresis and all the other cases admitted. In a good many cases of dementia praecox we shall, I believe, find that we have had a positive Wassermann reaction. Whether this indicates any etiologic relationship between the *Spirochaeta pallida* and the dementia praecox is dubious. Dermatologists used to say that about 15 per cent. of their infirmary practice was specific. This has to be taken into account when we draw conclusions as to the relation of the Wassermann reaction to paresis. We do not feel that there are any exceptions to the positive Wassermann in syphilis. It has been shown that cerebellar sclerosis is not incapable of making a condition resembling that of general paresis, which may account for the few cases in which it has been absent. In a series of forty-one cases studied, two were cases of cerebellar sclerosis. There might have been positive Wassermann reactions in those cases.

The spirochetes certainly do not inhabit the neighborhood of the vessels, and while this organism may not be responsible for all the lesions in paresis, the localization of the lesion in the brain in paresis would seem to favor this idea. One wonders, of course, whether in various other diseases the symptoms may not be due to death of the spirochetes rather than to any factors connected with the living organisms. In one case the effects were traced to the cerebrospinal sheath. Pain occurred as a result of treatment in a patient in whom pains had never before occurred. We wondered, therefore, whether this result might be due to toxic elements, or to the killing of the spirochetes. One must take into account the endotoxic results of the killing of the organisms by salvarsan. Some of the results of the so called provocative injections of salvarsan may be due to these endotoxic effects, the spirochetes being killed by the provocative dose, as the result of which there are symptoms which may then be succeeded by an improvement.

Dr. W. W. Graves, St. Louis: I have long held the opinion that without syphilis there is no paresis and no tabes. That conclusion is based on the observation of others and also on personal experience, extending over a number of years of observation not only of syphilitics whom I treated many years ago, but also of their wives and children. Not only do almost 100 per cent. of Wassermann reactions on the blood in paresis lead to that assumption, but the clinical signs also, which are invariably present when associated with laboratory signs, cause us to come to the same conclusion. During the past three years I have endeavored to recognize, if possible, by microscopic and other means, the virus of syphilis, and I shall be able to present at this meeting some evidence along lines showing that it is possible to infect rabbits with the virus of syphilis direct from the blood of general paretics.

There is one other point to which I should like to refer, one I have observed not infrequently in connection with the Wassermann reaction in general paresis. It is known that a certain number of paretics will give a negative Wassermann. This finding seems to depend somewhat on the time the Wassermann test is made; if immediately following a paretic attack, or during or coincident with the attack, the reaction will not infrequently be negative, while if made during the remission the reaction is almost invariably positive. I interpret the phenomenon in this way: The system is so overwhelmed by the sudden development of the ever-present virus that antibodies on which the Wassermann reaction in all probability depends are not produced, and hence it happens that negative reaction may be obtained even in general paresis.

Dr. Charles R. Ball, St. Paul: From a close observation of the cases reported, and most of them I have had an opportunity to observe over a number of months, it is my impression that the injections of sodium nucleinate exert a much better influence on the symptoms than either salvarsan or mercury. The patient who received the largest number of salvarsan injections—eight in all—after a short period of improvement rapidly grew worse. The two patients, who at present, except for their somatic symptoms, are apparently well, have resumed their former occupations. Both of these patients I am still keeping under antispecific treatment during this period of remission. It will be interesting to know what the influence of antispecific treatment will be during this period.

New York Infant Mortality to July 19 Compared with 1912.—According to the statistician of the New York Milk Committee, for the entire city, to July 19, 1913, there were 76.175 births against 74.597 for the corresponding period last year, an increase of 1,578. The total deaths, all ages, were 44.058 against 42,799 for 1912, an increase of 1,259. Deaths under 5 years were 12,115, against 12,005 for 1912, an increase of 110. The deaths under 1 year were 7,513 against 7,729 for 1912, a reduction of 216. The diarrheal deaths were 1,100 against 1,173 for 1912, a reduction of 73. Congenital debility deaths were 2,406 against 2,423 for 1912, a reduction of 17. Stillbirths were 3,823 against 3,720, a reduction of 103 in stillbirths to date. Though it is obvious that a large number of stillbirths occurring in New York are not reported, nevertheless, the figures from the reports are valuable in showing their relation in proportion to congenital deaths in early infancy.

THE VALUE OF SANITATION AS APPLIED TO RAILWAY AND OTHER LARGE CORPORATIONS

WITH SPECIAL REFERENCE TO THE PUBLIC WELFARE [*]

M. CLAYTON THRUSH, PH.M., M. D.
PHILADELPHIA

All large industrial corporations have the health of a number of human beings to protect, and while the majority of them have only the health of their own employees to maintain and watch over, railway corporations, whose duty it is to transport the public safely from one point to another, have a far greater and more important problem confronting them; and during the past twenty years the management of most of our large railway corporations has been giving this subject more and more consideration. As a result, a large number of important sanitary regulations have already been introduced, some of these being voluntary, others the result of legislative enactment of the various states through which the road passes. There is room, however, for far greater improvement and development along the same lines before an ideal standard is reached. The whole country is becoming interested in sanitation, and as soon as the people as a whole realize the value and importance of sanitation as applied to every industry of whatever kind, then and only then shall we reach the ideal for which we are striving.

The greatest responsibilities in this connection rest on the medical profession of the United States, and the American Medical Association should be the guiding "spirit" which controls the medical profession, both individually and collectively, in educating the public to a full realization of the importance of sanitation on the public welfare in all walks of life and all lines of business, industry and labor. Let us all work for a national Department of Health with a representative in the President's cabinet; let us all work for more stringent state laws on sanitation and public health and, finally, let us all work for the adoption of higher sanitary regulations by all large industrial corporations.

For convenience of classification I have divided the sanitary regulations as applicable to railway corporations into twelve classes as follows:

1. *Relief Department.*—This is a form of industrial insurance which has been adopted by a large number of railroads and should be adopted by all. Each employee pays a certain amount out of his wages each month, and, in case of sickness or injury, he receives in return so much each day while incapacitated from duty. The amount varies according to the class of insurance taken out; most of the roads pay more for accident than for sickness. The taking out of this insurance is voluntary with some roads and compulsory with others; the latter plan, however, is preferable, as the employee's family should always be protected. This department has supervision of the men when off duty on account of sickness, and a medical inspector is sent to visit the man's home to note his condition and to give him a "return-to-duty" card when he is well enough to return to work. This department likewise examines all new employees and determines whether or not they are physically qualified to perform the duties for which they apply. Most railways have established a pension fund for employees retired through age, years of service or physical incapacitation, and this is under the supervision of the relief department.

2. *Efficiency Examination of Employees.*—This department should give every man in the "operating department" of the road a thorough physical examination at reasonable intervals, testing particularly the vision, the hearing and for color-blindness, as well as general appearance, heart, kidneys and lungs. This is of great importance in maintaining a high standard of efficiency, which is of advantage both in greater safety for the public and in larger financial returns for the road.

3. *Sanitary Inspection of Buildings.*—There should be a department for the systematic inspection of all the buildings of the company, including passenger and freight stations, and all shop, storage and office buildings, which should note the ventilation, plumbing, condition of diet-kitchens and rooms for the storage of food products and live stock. The drinking-water should be carefully analyzed at reasonable intervals, and proper receptacles should be provided for holding this water. The abolition of the common drinking-cup should be insisted on, and sanitary cups should be provided either free or at a nominal price. This department should include the supervision of the loading of freight-cars with foodstuffs and live stock, and also observe that proper sanitary measures are utilized to protect the health of the men employed in the various construction and repair shops of the company.

4. *Sanitary Inspection of Road-Beds.*—Inspection should be made at reasonable intervals by men properly qualified to note especially that proper drainage canals are provided at the sides of the tracks, that all tunnels and tubes are properly ventilated and also that all water courses are kept free from filth and stagnant material.

5. *Inspection of New Construction.*—All new constructive work, whether road-beds or buildings, should be done on a sanitary basis, and should be approved by this department. Whenever a new piece of work is undertaken, the camp, drinking-water, etc., should all be under sanitary regulations.

6. *First Aid to the Injured.*—This department should require every employee to be properly instructed in rendering first aid to the injured, whether passenger or employee; and each employee should be given a sanitary package containing proper materials for rendering such service, and he should be taught how to use this material. Each employee should have this package with him whenever he is on duty.

7. *Sanitary Inspection of the Rolling Stock.*—This would include the frequent inspection of all passenger and Pullman coaches, and also all freight-cars which transport live stock and perishable merchandise. All cars should be kept in a proper sanitary condition, including the diet-kitchens of dining cars. The drinking-water and the condition of the receptacles holding it are matters of the greatest importance, and only sanitary drinking-cups should be permitted. Every one who has traveled, even to a minor degree, has witnessed the uncleanly and often filthy manner in which the drinking-water receptacles on passenger coaches are filled with ice and water, this work being usually performed by the cheapest, ignorant laborer, who handles the ice with dirty and unwashed hands, often reeking with coal dirt and "smear" from off the sides of the car, which he grasps in order to raise himself to the top of the car; and sometimes his hands are contaminated with what is far worse, namely, the infectious material of some venereal disease, which is particularly common among this class of employees. The same conditions often apply to the filling of the

---

[*] Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

water "coolers" of passenger stations. May we not reasonably ask, "Of what value is the individual drinking-cup in protecting the public, when the water is already polluted with poisonous material?"

Of course "spitting" in all public places cannot be too strongly condemned; especially does this apply to the passenger coach of a railway train. Almost all the cooks, dishwashers and kitchen-helpers who participate in the preparation of the foodstuffs used in dining-cars and in the restaurants of our railways are colored; and the great majority of the waiters also belong to this class; it is a well-known fact that people of this class frequently suffer from tuberculosis, diseases of the eye and skin, particularly syphilis and other communicable diseases. Last December the attention of the newly elected president of the Pennsylvania Railroad (Samuel Rea) was called to the facts which are here presented. It is refreshing to note, in a bulletin issued in April, 1913, by the Pennsylvania management, the following result, and it is earnestly hoped that all railways will speedily adopt the same regulations.

Waiters Must Be Healthy

THOSE HAVING COMMUNICABLE AILMENTS MUST LEAVE

> The following extraordinary precautions against the transmission of communicable diseases by the dining-car and restaurant employees have been adopted:
>
> There is to be a quarterly physical examination of every employee who has anything to do with the preparation or serving of food. Dishwashers, kitchen-helpers, cooks and waiters must undergo an examination every three months, and only a 100 per cent. report on their physical condition will permit their remaining in the service, while those suffering from tuberculosis, diseases of the eye or skin, and any other communicable disease, may not be employed in any capacity in which they might come in contact with food; further precaution will be taken in debarring them from employment in places in which linens and tableware are kept.

Now let us consider the question of the drinking-water, another very important subject.

SURGEON-GENERAL BLUE ANNOUNCES STRICT REGULATIONS

> Washington, May 16, 1913.—Four months ago notice was served on all interstate railway and steamboat carriers that the drinking-water provided by them for the use of passengers must be certified as free from anything liable to cause disease in man. Surgeon-General Blue of the Public Health Service to-day announced the promulgation of regulations relative to the certification of the water and ice furnished to passengers in interstate traffic. They are as follows:
>
> "Samples of water and manufactured ice from each and every source of supply should be subject to bacteriologic and chemical examination at least once in every six months by the proper state or municipal health authority within whose jurisdiction the supply is obtained, or by other person or persons competent to make such examinations, and whose result will be accepted by the state or municipal health authority whose duty it is to issue certificates. Each new crop of natural ice should be examined and certified before use. The common carrier desiring a certificate of the state or municipal health authority within whose jurisdiction the water or ice is obtained should make application therefor." The Pennsylvania Railroad, as an advance step toward complying with these regulations, on May 1, 1913, ordered that all water receptacles on all passenger-coaches should be sterilized with steam at least once a week.

Pure Water on Trains

Surely this is a step in the right direction, and this whole subject is of vital importance to every human being, as we must all eat and drink at reasonable intervals. This is but the commencement of a "sanitation crusade" which I trust will spread across this whole country.

These regulations should apply with the same degree of importance to steamship companies, hotels, restaurants, clubs, pleasure resorts and in fact all places which handle foodstuffs for public consumption. It is the duty of the legislature of each and every state in the Union to adopt suitable laws on sanitation which will insure to every person within its borders pure food and drinking-water, in all public places of whatsoever character; this can be accomplished only by adopting strict sanitary regulations, comprising not only those that are herein described, but also such others as may be recommended by properly qualified health officers to meet the exigencies as they may arise.

People should protect themselves and their children and force cleanliness on careless dealers by refusing to patronize soda-water fountains, etc., where the glasses are not thoroughly washed after each use. Hasty rinsing in cold water may appear to clean the glasses, but it is only an apology. Glasses or cups with broken or rough edges present another danger.

The use of the common roller-towel in public places is just as dangerous as the common drinking-cup, and all that has been said of the latter applies with just as much force to the former. Persons should be especially careful not to use a common towel near their eyes, as dangerous eye-diseases, which may cause blindness, are often contracted in this way. An enlightened public sentiment is absolutely necessary before we can hope to eliminate entirely all these grave and unnecessary menaces to the public welfare.

8. *Supervision of Railway Surgeons.*—All surgeons of a railway system should be governed by a directing head or surgical director; they should be required to make stated reports of all duties performed, and a certain standard of efficiency should be required of them.

9. *Medicolegal Department.*—This department alone, if properly conducted, would save the company many thousands yearly. In the case of all wrecks this department should be promptly notified, and competent men should be hurried to the scene of the disaster to take charge of the injured, see that proper surroundings are provided for their care, note the extent of their injuries, and keep a close supervision of every case until a settlement is made releasing the company from further claim; or if the case goes to court for adjustment, this department would take charge of the medical testimony for the company.

10. *Supervision of Hospitals and Dispensaries.*—All hospitals and dispensaries that are conducted by the company should be properly managed, and competent surgeons should always be on duty ready to relieve the injured.

11. *Purchasing of Medical and Surgical Supplies.*—This should be done by competent and experienced persons who are familiar with the best available sources for purchasing the needed supplies.

12. *Department of Statistics.*—A complete system of records should be kept at the general office of all injuries and deaths that occur on the road, and also a complete record of each employee from the medical point of view. These facts would prove of great value at times for reference.

CONCLUSIONS

The following recommendations are applicable to all large railway corporations as the result of these observations:

1. All railway corporations should have a "department of health and sanitation," which should direct and control all matters pertaining to the medical welfare of both its employees and the public.

2. There should be an expert sanitarian in charge of this department who should be a doctor of medicine, and he should be given a suitable title, such as "director of health and sanitation." He should have the same authority in this department that the general manager has in the "operating department" of the road.

3. He should work directly in conjunction with the general manager, both being under the supervision of the president of the company.

4. There should be twelve department superintendents, each of whom should have direct supervision of a particular department as herein enumerated; and these should be controlled and managed by the medical director.

5. The director's office should be located at the general headquarters of the company.

6. The adoption of this plan would consist in consolidating and systematizing all the various medical departments of the road under one directing head or management, resulting in more efficient service with less expenditure of capital and producing a condition of greater safety and protection to the traveling public, who pay for and should receive "safe transportation under sanitary regulations."

3705 Spring Garden Street.

ABSTRACT OF DISCUSSION

Dr. W. C. Rucker, Washington, D. C.: I have a personal interest in this matter because, as chief of the division of interstate quarantine, it comes within my immediate purview. Under the law of Feb. 15, 1893, regulations may be made for the prevention of the spread of disease from one state or territory into another state or territory, or the District of Columbia. That is translated as meaning that the common carriers may be regulated in order to prevent the interstate spread of disease. The Supreme Court of the United States, in a decision rendered not long ago, decided that a common carrier—whether it was a firm, corporation or person—was engaged in interstate traffic when it carried a person, freight, or a letter that was destined for a point outside a state.

The order of May 16, 1913, which was quoted by Dr. Smith, was a set of instructions which were issued to cover Amendment No. 6 to Paragraph 3 of the General Regulations. This amendment includes the following points: In the first place, the sources of water to be used as drinking-water by passengers in interstate traffic shall be certified by the proper state or municipal health officer within whose jurisdiction it is obtained as being incapable of conveying disease, or, in other words, as not containing disease organisms. This water shall be certified once every six months. The amendment further requires certification of ice in the same manner. This ice must be examined once every six months, if it is artificial ice, and for every crop if it is natural ice. The ice shall be so handled that it shall not be contaminated with disease-producing organisms. The water-containers from which this water is dispensed to the general public shall be sterilized once a week while in operation. That regulation is being carried out. The railways and steamboats are doing their best to comply with it. One railway is spending $46,000 for the purpose of putting in tanks in which the water and ice do not come in contact. Another railway is spending about $15,000 putting in tanks that are to be filled from the roof only. That is necessary, because in many states in which the low tank is used, labels off beer-bottles, nipples off of nursing-bottles, etc., are found in the tanks when opened for cleaning. The common drinking-cup is absent from the common carriers in the United States, as a result of an amendment to the interstate quarantine regulations which forbids absolutely that a common carrier engaged in interstate traffic shall supply common drinking-cups to the traveling public. The use of a common roller-towel is equally against the regulation. A depot or a waiting-room used by common carriers is just as much a part of the system that is engaged in interstate traffic as the engine or the roundhouse, and the regulations apply with equal force to these places.

Dr. A. M. Hume, Owosso, Mich.: I have had in charge the sanitary work of a small railway, in addition to the management of the surgical department and all of the departments that would be included in the suggestions offered by Dr. Smith. In my opinion it is not practicable to divide this work into so many departments. Greater proficiency will be attained if the work is put in charge of a competent man who is a railway surgeon and sanitarian, and who has proper executive ability.

The common towel and the common drinking-cup have been abolished from almost all the railways in the country through the order of the U. S. Public Health Service, reinforced by the regulations of some of the state boards of health. The Michigan State Board of Health abolished the common drinking-cup prior to the U. S. Public Health Service order, and there has been a willing compliance by that board, and others too, I presume, with all of the regulations that have been issued by the U. S. Public Health Service. Unfortunately, however, this right attitude of state boards of health is not universal. At the meeting of the chief surgeons of railways held in Chicago not long ago, when the subject of certified drinking-water for use on trains was under discussion, there was an expression from at least one state board of health that it proposed to run its own business and would not allow dictation by the U. S. Public Health Service. When that Service prohibits the use of only such drinking-water as has been certified to by the state board of health, and state boards refuse to certify any water, the railway companies are placed between two fires.

Some boards have intimated that they would do this work if paid for it, but we contend that, as this is a measure for the protection of the public health, the public and not the railway companies should bear the expense of such protection. The willingness of the railway companies generally to comply with this regulation is not questionable; but the willingness of some state boards of health to do their part is very questionable.

Dr. Albert E. Campbell, Chicago: I was in private practice and a health officer when I was asked to become health officer of the Illinois Central Railroad Company. The water-tanks on our system were sterilized eight or ten months before the U. S. Public Health Service ordered it done.

Dr. C. C. Pratt, Mankato, Minn.: I have frequently seen the news-agent take a new drinking-cup, drink from it, and then fold it and put it back in his stock for sale to the traveling public.

Dr. R. Q. Lillard, Nashville, Tenn.: I should be recreant to my trust if I did not say a word for the railway. Every railway system in Tennessee is heartily in accord with the U. S. Public Health Service order, and is most willing to carry it out to the letter. Furthermore, they heartily acquiesce in any proposition that will protect the traveling public.

Dr. Margaret A. Ryan, Brookston, Minn.: Why is it that since they have removed the roller-towel, they do not replace it with the sanitary paper towel?

Dr. M. Clayton Thrush, Philadelphia: I fully agree with Dr. Rucker that the U. S. Public Health Service has already done splendid service along these lines; I think that the railways will continue to improve existing conditions. We cannot expect a railway system to take up a new order and perfect it in a few months; all the railway systems continue to possess many objectionable features, but these are being eliminated rapidly. The system that I have expounded here was intended for large railway corporations. Every railway would, of course, make its own system of classification; but this would merely be a guiding system, which can be modified to suit the various railways according to the size of the corporation and the various other underlying conditions.

MIXTURES OF THE UNITED STATES PHARMACOPEIA

OLIVER T. OSBORNE, M.D.
Professor of Therapeutics at Yale; Vice-President of Pharmacopeial Convention
NEW HAVEN, CONN.

This paper is to complete the series of three which I have recently written on the subject of a better, more limited Pharmacopeia.[1]

I seriously question the advisability of including the following mixtures in the next Pharmacopeia, on the ground that many of the ingredients are needless and useless, and, in fact, that these multiple mixtures are unscientific. The preparations in questions are:

Elixir adjuvans.
Elixir ferri, quininae et strychninae phosphatum.
Extractum colocynthidis compositum.
Infusum sennae compositum (black draught).
Liquor ferri et ammonii acetatis (Basham's mixture).
Liquor sodii phosphatis compositus.
Massa hydrargyri.
Mistura glycyrrhizae composita (brown mixture).
Mistura rhei et sodae.
Pilulae catharticae compositae.
Pulvis aromaticus.
Pulvis cretae compositus.
Syrupus hypophosphitum compositus.
Syrupus sarsaparillae compositus.
Syrupus scillae compositus.
Tinctura benzoini composita.
Tincture lavandulae composita.

This is the age in which we are analyzing and criticizing everything in the therapeutic line, and why should we accept as gospel, and as above criticism, such mixtures as the preceding titles represent? We decry proprietary mixtures and "shotgun" prescriptions; why do we accept these legacies of ancient vintage because the Revision Committee of the United States Pharmacopeia sees fit to perpetuate such therapeutic nonsense?

Let it be repeated and emphasized, as I have done, that the omission from the next Pharmacopeia of any drug or preparation does not deprive a physician from obtaining that drug or preparation by the standard of the last Pharmacopeia in which it was described. The omission of useless drugs and worthless and unnecessary preparations from the next Pharmacopeia means that the Pharmacopeia is so much more up to the present date of science and therapeutic knowledge. It should also be understood that the object of the Pharmacopeia should be to standardize useful drugs and their most elegant (pharmacally) preparations, but its object should not be to show how elegantly a heterogeneous mass of substances can be combined according to the art of pharmacy.

To discuss these mixtures understandingly I shall group them according to their therapeutic uses.

One should give the drug he thinks advisable in the pleasantest manner possible, and he should select the best preparation of the most active drug to accomplish the object desired. If this drug tastes disagreeable it should be made more palatable, if possible. It should rarely be combined with sweet syrups, lest the bad taste be made more persistent. If the drug is irritant, it should not be given on an empty stomach unless with a large amount of water, or by adding something to the prescription that will prevent irritation of the stomach. Just how the drug should be administered, whether in the form of liquid, powder, wafer, capsule or pill, must of course depend on the character of the drug, the size of the dose, and the object aimed at. Presumably a drug given in solution is more rapidly absorbed than one that is not. This may not always be the fact.

Elixir Adjuvans, U. S. P.

This elixir was official in the last Pharmacopeia and has been approved for the next Pharmacopeia. The formula is the following:

- Fluidextract of glycyrrhiza.
  - Glycyrrhiza.
  - Glycerin.
  - Ammonia water.
  - Alcohol.
  - Water.
- Aromatic elixir.
  - Compound spirit of orange.
    - Oil of orange peel.
    - Oil of lemon.
    - Oil of coriander.
    - Oil of anise.
    - Alcohol.
  - Syrup.
  - Purified talc.
  - Alcohol.
  - Distilled water.

These compound preparations, namely, fluidextract of glycyrrhiza and aromatic elixir, are put together in the proportion of 12 parts of the former to 88 parts of the latter in each 100 parts of the mixture. The instructions are to mix, and filter if necessary. In this mixture it is too bad to spoil the nice (?) distilled water of the aromatic elixir with the plain, every day water of the fluid extract of glycyrrhiza, but this was of course not noted by the advisory board of the last Pharmacopeia.

This preparation, elixir adjuvans, and the aromatic elixir may be considered as cocktails or as menstrua for other ingredients of a cocktail, but represent substances that should ordinarily not be given to a person who is ill. We tell our patients not to take highly spiced foods, not to use irritant and aromatic condiments, and then order such combinations as the above.

The question is whether an elixir composed of the above ingredients is ever needed in the practice of medicine. It absolutely is not, and the care and time devoted to the preparation of the elixir adjuvans in all its details is labor lost. It may taste well, but it is not necessary to use such a mixture of tastes to disguise a bad-tasting drug, and the number of tastes put into this one preparation, namely, the elixir adjuvans, would defy a decision by an expert tea-taster as to just what the taste was that he tasted. In other words, this multiple mixture is unnecessary and should not appear in the next Pharmacopeia, i.e., it should not appear in a scientific book of the year 1913 or 1914.

Tinctura Lavandulae Composita, U. S. P.

Oil of lavender flowers.
Oil of rosemary.
Cinnamon.
Cloves.
Nutmeg.
Red saunders.
Alcohol.
Water.

This very elegant tincture or cocktail (about two-thirds of its bulk being alcohol) for the esthetic treatment of hysterical conditions and nervous indigestions should not be dignified by officialization in the next Pharmacopeia. These patients could be given small doses of any good cocktail and the result would be the same. Let us not cater to such aromatic, alcoholic fallacies. We should be honest with ourselves and remember that such treatment is treatment by alcohol.

---

[1] The Journal, May 10, 1913, p. 1427, and June 28, 1913, p. 2039.

TONIC MIXTURES

The following are tonic or alterative mixtures official in the last Pharmacopeia and approved by the Executive Committee for the new one:

Elixir ferri, quininae et strychninae phosphatum.
Liquor ferri et ammonii acetatis (Basham's mixture).
Syrupus hypophosphitum compositus.
Syrupus *sarsaparillae compositus.*

The ingredients of these mixtures are the following:

Elixir Ferri, Quininae et Strychninae Phosphatum, U. S. P.

- Soluble ferric phosphate.
- Quinin.
- Strychnin.
- Phosphoric acid.
- Ammonium carbonate.
- Alcohol.
- Acetic acid.
- Ammonia water.
- Distilled water.
- Aromatic elixir.
    - Compound spirit of orange.
        - Oil of orange peel.
        - Oil of lemon.
        - Oil of coriander.
        - Oil of anise.
        - Alcohol.
    - Syrup
    - [Purified talc]
    - Alcohol
    - Distilled water.

This is no parody but absolute facts copied from the Eighth Decennial Revision of the United States Pharmacopeia. How many physicians, after reading the above, will deliberately and sanely order this tonic "soup"?

It is hardly necessary to discuss the value of the mixture. A chemist could tell us whether or not the phosphoric acid or the acetic acid would combine with the quinin and the strychnin to make phosphates or acetates, whether or not the ammonia water would counteract the acidity of the phosphoric acid and the acetic acid, just what would become of the ammonium carbonate, just exactly what the alcohol is doing in preventing or promoting chemical changes, and exactly what the patient really receives when he takes a teaspoonful of this chemical nonsense.

Theoretically, the patient receives about 1¼ grains of soluble ferric phosphate, unless something happens to this phosphate in the chemical combination. Likewise, he receives a little more than ½ a grain of quinin and about 1/60 grain of strychnin. The dose of this tonic is stated to be 4 c.c. or a fluidram, and it generally is administered three times a day. The preceding approximate doses that the patient would actually receive are based on the probable administration of a teaspoonful at a dose.

Do the scientific physicians of the year 1913 desire this hodgepodge mixture officialized in the next Pharmacopeia?

Liquor Ferri et Ammonii Acetatis (Basham's Mixture), U. S. P.

- Tincture of ferric chlorid.
- Dilute acetic acid.
- Solution of ammonium acetate.
    - Ammonium carbonate.
    - Dilute acetic acid.
- Aromatic elixir (seven ingredients besides alcohol and water, see above).
- Glycerin.
- Water.

This preparation has long been considered of special value in disease of the kidneys, but as usual with many such mixtures it has been inherited and has been passed on from generation to generation without a question as to the reasons for the combination or its advantages over more simple preparations. In this mixture the iron probably becomes an acetate, and part of the ammonium acetate becomes ammonium chlorid. It decomposes more or less rapidly and should be freshly made when ordered.

Theoretically the aromatics in this preparation are not needed, even if they did no harm, in kidney defect.

It seems absurd to perpetuate a mixture of this number of ingredients when the whole object aimed at is to give iron in a pleasant and diuretic form. The tincture of the chlorid of iron may be given in from 1 to 3 drop doses in a small glass of freshly made lemonade, or it may be given in a mixture such as the following:

		gm. or c.c.		
℞	Tinctura ferri chloridi....	5		flʒ iss
	Syrupi acidi citrici.......	25	or	fl℥ i
	Aquae ....q. s. ad	100		fl℥ iv

M. et Sig.: *A teaspoonful, in water, three times a day, after meals.*

Or, the saccharated oxid of iron *(Eisenzucker)* may be given in tablet form; or the reduced iron, in small amount, may be given in a dry capsule; or the Blaud pill may be given. They will all answer the same purpose as far as the tonic effect is concerned. In other words, it is an insult to our intelligence to perpetuate this mixture just because it has a good inheritance and because it is used in almost every hospital in the country.

Syrupus Hypophosphitum Compositus, U. S. P.

Calcium hypophosphite.
Potassium hypophosphite.
Sodium hypophosphite.
Ferric hypophosphite.
Manganese hypophosphite.
Quinin.
Strychnin.
Sodium citrate.
Diluted hypophosphorous acid.
Sugar.
Water.

It is not necessary to repeat the argument against this mixture. The value of hypophosphites is mythical, and that being a fact, it should throw the whole mixture into disrepute. (See discussion of hypophosphites, The Journal, March 8, 1913, p. 747.)

Syrupus Sarsaparillae Compositus, U. S. P.

Fluidextract of sarsaparilla.
Fluidextract of glycyrrhiza.
Fluidextract of senna.
Sugar.
Oil of sassafras.
Oil of anise.
Oil of gaultheria.
Water.

There is absolutely no excuse for the next Pharmacopeia perpetuating the sarsaparilla fraud. The sarsaparilla nostrums on the market are enough to condemn any sarsaparilla mixture as a medicine, and the value of sarsaparilla as a drug is nil. Therefore, this mixture of spices and laxatives, glycyrrhiza and senna, is utterly uncalled for. If the object of this mixture is only as a menstruum for a bad tasting drug, such as potassium iodid (in which the latter was for a long time frequently administered) it is a failure. It did not improve the taste, and (it has long since been decided) was a very poor method of administering potassium iodid. It is absurd for this preparation to enter the next Pharmacopeia.

EXPECTORANT MIXTURES

Preparations for this object that have been approved for the next Pharmacopeia, and are inexcusable multiple mixtures, are:

Mistura glycyrrhizae composita (brown mixture).
Syrupus scillae compositus.
Tinctura benzoini composita.

Mistura Glycyrrhizae Composita, U. S. P.

Pure extract of glycyrrhiza.
Syrup.
Acacia.
Camphorated tincture of opium.
    Powdered opium.
    Benzoic acid.
    Camphor.
    Oil of anise.
    Glycerin.
    Diluted alcohol.
Wine of antimony.
Spirit of nitrous ether.
Water.

This long, much-used preparation, believed in by everyone, many times used as the last ingredient or menstruum of a multiple cough mixture, can be criticized only in a spirit of bravado and temerity. It is like attacking a household god. From beginning to end it is a fool mixture. The mere fact that a patient has a cough is no reason that he should also be forced to have a sour stomach. I have repeatedly urged that sweet syrups should not be given as menstrua for the administration of some efficient expectorant drug. This mixture should not be used for the following reasons:

1. If a laxative action is required it may be induced in a much better way than by this extract of glycyrrhiza.

2. This dear old time-honored paregoric, which alone contains six ingredients, which it has been claimed was introduced into medicine at the Leyden University early in the eighteenth century, contains too small an amount of opium to be of any sedative value in this compound licorice mixture.

3. It takes but little water to precipitate the camphor of the mixture. The addition of paregoric to any cough mixture is absurd, as there always is a precipitate. If some sedative or opiate is needed, morphin, codein, or even heroin may be used to very much better advantage and with very much more homogeneous results. The dose of opium administered by paregoric in a mixed solution is absolutely uncertain.

4. As I believe there will be no wine of antimony in the next Pharmacopeia, the antimony that will be used in the mistura glycyrrhizae composita is not determinable at this writing. Be that as it may, antimony should, theoretically, according to modern pharmacologic and therapeutic belief, not be given internally at all, with the possible exception of tartar emetic being used in small doses, more or less frequently repeated, to the point of nausea (which should occur within a few hours) in an acute inflammation of the upper air passages. There is no other legitimate use for antimony. The addition of antimony to a cough mixture to be used any longer than the first twenty-four hours, in any dose that would be tangible, is not good therapy.

5. Sweet spirit of niter to be of value must be freshly made. Nitrites will cause more or less dilatation of the peripheral blood-vessels, and the sweet spirit of niter, when freshly made and frequently administered, in small doses, with a patient in a warm room and covered up, may cause perspiration. When such is administered in cold water, and the patient is not too warm, it may cause some slight increase in the amount of urine. To obtain these actions at all the drug must be frequently administered, and its activity in such a combination as the preceding brown mixture is too doubtful for thoughtful consideration.

It is not desired to intimate that the preparation would do any harm, except possibly to cause nausea from its sweetness. It certainly would not increase appetite. It might constipate, or it might cause looseness of the bowels, depending on the drug to which the patient was the most susceptible, the opium and camphor or the licorice. But when simple drugs, associated to meet the indications in the individual patient will act therapeutically most successfully, why should the next Pharmacopeia honor this old-time mixture with its ratification?

Syrupus Scillae Compositus, U. S. P.

Fluidextract of squill.
Fluidextract of senega.
Tartar emetic.
Purified chalk.
Sugar.
Water.

This is another combination with antimony, and the advisability of using antimony internally has already been discussed. There is no excuse for ever using senega; there is little excuse for ever using the nauseating, disgusting squill as an expectorant.

Also, each 100 c.c. of this mixture contains 75 gm. of sugar, i. e., in every teaspoonful of this sickish, sweetish, nauseating, nasty mixture there is contained 3.75 gm., or about 57 grains, of sugar. These facts are certainly enough to condemn the use of this old "hive syrup," the hobby of our great-great-great-grandmothers.

Tinctura Benzoini Composita, U. S. P.

Benzoin.
Purified aloes.
Storax.
Balsam of tolu.
Alcohol.

This preparation is now rarely given internally, although the last Pharmacopeia gives the dose as 2 c.c., *30 minims*. This mixture also partakes of the past, when the preparation was frequently used as an expectorant, administered internally. It is now generally conceded that these balsams are not of great benefit to the stomach, and that if a patient needs the laxative effect of aloes it had better be administered in some more *pleasant manner* and not given frequently as a cough mixture is supposed to be administered. Therefore, internally, the preparation is a failure. It is frequently used for inhalation, and the balsams and benzoin thus vaporized are doubtless of value in many conditions of the throat, larynx, and larger bronchial tubes. But why should aloes be administered in a preparation whose only value is that of an inhalant? The preparation would also be better without the irritant action of storax.

CATHARTIC MIXTURES

Extractum colocynthidis compositum.
Infusum sennae compositum.
Liquor sodii phosphatis compositus.
Massa hydrargyri.
Mistura rhei et sodae.

Infusum Sennae Compositum, U. S. P.

Senna.
Manna.
Magnesium sulphate.
Fennel.
Water.

This ancient and nauseating mixture has been accepted for the new Pharmacopeia. No one could question its efficiency, but everyone could question the object of the manna. The dose of this nauseating drink is 4 fluid ounces, or 120 c.c., and the druggist is supposed to make 1,000 c.c. of the preparation. The question is how long it would take to make it, and how long this preparation should be kept, and what a dose of magnesium sulphate given in this form would cost the patient. The whole proposition is bad sense pharmacally, economically and therapeutically. If the patient needs a cathartic, he can receive magnesium sulphate in some pleasant effervescing form, or he may be given some other of the many simple cathartics.

Liquor Sodii Phosphatus Compositus, U. S. P.

Sodium phosphate.
Sodium nitrate.
Citric acid.
Distilled water.

Perhaps there is nothing very serious the matter with this mixture, but it is entirely superfluous. It has no advantage whatever over a Seidlitz powder or the liquor magnesii citratis. It is an unnecessary redundancy in the Pharmacopeia, and is only mentioned here on that account.

Massa Hydrargyri, U. S. P.

Mercury.
Glycyrrhiza.
Althaea.
Glycerin.
Honey of rose.

To attack this old "blue mass" is like another attack on a household god, and one is in danger from the shades of his ancestors, to say nothing of attacks by his professional brethren, when he states that this preparation is not needed and should not be perpetuated. The ridiculousness of the "honey of rose" in a cathartic mass is self-evident, in fact, the modern physician has but to read these ingredients to agree that the mass of mercury should be an ancient joke.

Mistura Rhei et Sodae, U. S. P.

Sodium bicarbonate.
Fluidextract of rhubarb.
Fluidextract of ipecac.
Glycerin.
Spirit of peppermint.
Water.

This preparation is specifically a hospital preparation, and if it was estimated how many times this preparation was used in hospitals in a single day in the United States the impression would be made that it was an essential in curing hospital patients. The hospital graduates then use this preparation more or less frequently throughout their professional life. If we analyze this preparation the following facts should be noted:

1. The object of sodium bicarbonate is to overcome hyperacidity of the stomach, or to increase the alkalinity of the blood. If this preparation is to be given before meals, the sodium bicarbonate would probably soon be neutralized by the hydrochloric acid. If it was given after meals, it would perhaps lengthen the duration of the activity of the starch changes caused by the saliva. The question would be, What action of sodium bicarbonate is desired, and is that indication met in this combination?

2. The rhubarb is of course a laxative. It is a question whether this bad-tasting stuff is needed or advisable three times a day, or is necessary to obtain an action of the bowels.

3. The ipecac is more or less of a gastric stimulant, and if in any amount, would cause nausea and perhaps vomiting. The dose is very small and the action is probably nil. If the dose is a teaspoonful of the preparation, the patient would receive 0.015 c.c., or about ¼ of a minim of ipecac, a perfectly negligible dose; in other words, objectless.

The glycerin is in considerable amount, and the glycerin might act as a laxative, or, if given on an empty stomach, could cause vomiting.

The peppermint is of course a carminative.

The preceding mixture, though more or less harmless, and often apparently of benefit, is so markedly inferior to more scientific medicinal treatment that modern physicians should abandon its use, and it should be eliminated from hospitals as partaking of the nature of a nostrum, and certainly should not be perpetuated in the new Pharmacopeia.

Pilulae Catharticae Compositae, U. S. P.

Compound extract of colocynth.
  Extract of colocynth.
  Purified aloes.
  Cardamom.
  Resin of scammony.
  Soap.
  Alcohol.
Mild mercurous chlorid.
Resin of jalap.
Gamboge.
Diluted alcohol.

To attack this time-honored and much-used cathartic again requires a spartan temperament, but I will wager that not one physician in twenty-five remembers the ingredients when he orders the cathartic pill.

Is it necessary, in order to obtain catharsis, to give this mass of cathartic drugs? Those of us who order one simple drug for such action obtain the same results as those who use this mixture. It certainly will be impossible to eradicate this from the Pharmacopeia, but I would urge every physician who orders this preparation, especially every surgeon, please to note the drugs that he administers. Many of these ancient cathartics should be removed from the Pharmacopeia.

The following two compound powders are unnecessary:

Pulvis Aromaticus, U. S. P.

Cinnamon.
Ginger.
Cardamom.
Nutmeg.

It is rarely advisable to give a lot of spices to a patient who is ill. We are constantly endeavoring to prevent the use of highly seasoned food, and it seems hardly worth while to officialize a combination of these aromatics. If an aromatic is needed, any one may be selected; a mixture would be generally contra-indicated.

Pulvis Cretae Compositus, U. S. P.

Prepared chalk.
Acacia.
Sugar.

If prepared chalk is needed as a sedative for the bowels or as an alkali for the stomach, its combination with sugar is certainly not physiologic. As a general axiom, in all kinds of indigestions sugar is more or less contra-indicated, and certainly it is not advisable to combine it in 50 per cent. strength (as is done in this mixture) in a preparation used as a medicine.

252 York Street.

THE SANITARY RECORD OF THE SECOND DIVISION OF THE U. S. ARMY IN TEXAS

R. B. MILLER, M.D.
Major Medical Corps and Late Sanitary Inspector of the Second Division of the U. S. Army in Texas
WASHINGTON, D. C.

The first regularly organized division of the United States Army called into the field since the Civil War was mobilized at Texas City and Galveston, Tex., March 1, 1913. The troops encamped at Texas City numbered approximately 8,500 and those at Galveston 3,500.

The camp ground at Texas City had been selected in dry weather, when it presented a favorable appearance; but when actually occupied, after the spring rains, it proved to be badly drained. The soil was of clay and impervious, conditions usually considered unfavorable to health. In spite of such ditching as it was practicable to do, after heavy rains the water stood in the tents of both officers and men. By the first of April a better site had been selected and put in condition for occupancy by a comprehensive system of surface drainage, carried out under the supervision of the engineer officers of the division.

The principal sanitary requirements for a camp of this kind are, generally, as follows:

1. An ample supply of pure water.
2. An efficient system of excreta disposal.
3. Protection of the command against typhoid and small-pox by vaccination.
4. The prevention of soil pollution.
5. The prevention of dissemination of disease by flies and mosquitoes.
6. Means of insuring personal cleanliness.
7. Prophylaxis against venereal disease.

The first requisite, a pure water-supply, had been provided before the arrival of the troops by an extension into the camps of the water-supplies of Texas City and Galveston, respectively.

Excreta disposal is provided for in the Texas City camp by the use of pits, one for each company, from 5 to 7 feet deep, covered by box seats with ten holes in each, provided with self-closing lids and constructed so as to be fly-proof. The boxes are placed over the pits and the contact with the ground made fly-proof by banking with soft earth or sand. Once daily the boxes are turned over and the pits burned out, 10 pounds of hay and 1 gallon of crude oil being used for this purpose. Careful daily inspection by sanitary officers is necessary to insure the latrines being kept actually fly-proof. The latrine seats are scrubbed daily. When the pits become filled within two feet of the top they are covered over and new ones dug.

Every officer and man, as well as all civilian employees, not already protected, was required to be vaccinated against small-pox and typhoid fever.

Soil pollution is prevented by disposing of all solid and liquid garbage in improvised incinerators constructed at each kitchen by soldier labor. All organic waste is in this way disposed of as it occurs and no accumulation is permitted. Picket lines are kept carefully policed and all manure is hauled some distance from camp and burned.

Flies are prevented from breeding, so far as possible, by the careful disposition of manure, garbage and other organic waste as outlined and by preventing their access to the latrines. A number of flies come into camp from the neighboring town and others are bred on the surrounding prairie where the animals are grazed. To destroy these flies each company has provided itself with several large home-made fly-traps, which are placed outside the kitchen doors and in other places where flies congregate. These traps are an unqualified success. All kitchens and mess-halls are screened. The small number of flies in camp has been a matter of general comment.

Mosquito breeding is partially controlled by draining and oiling. We have also been assisted in our mosquito campaign by an unusually dry summer. The country surrounding the camp at Texas City is, however, so low and flat that the breeding of mosquitoes cannot be entirely controlled by a reasonable expenditure of labor and money. Officers and men are therefore required to sleep under the mosquito-bars, and all cases of fever, of whatever nature, are immediately placed in screened wards in the field hospital.

The men have access to a salt-water beach for bathing and in addition fresh-water showers are provided.

Tents are placed at convenient points, with attendants constantly on duty, in which men who have been exposed to venereal disease are, on their return to camp, required to take prophylactic treatment. This consists of irrigating the anterior urethra with a 2 per cent. protargol solution and anointing the penis with a 30 per cent. calomel ointment.

The results, as shown by the sick-rate, have been better than in any other camp the army has ever had. For the five months from March 1 to July 31, there has not been a single case of typhoid or paratyphoid fever among the personnel of the camp. Malaria and dysentery have been practically absent and, with the exception of a short epidemic in one brigade, after an absence of a week from its regular camp, there has been comparatively little diarrhea.

The constantly non-effective rate from all causes has been 1.14 per cent., of which 0.20 per cent. was due to injury, making the average rate from sickness 0.94 per cent. With a constant mean strength of 11,373 men, there have been, during the five months the division has been in camp, sixteen deaths, ten of which were due to injury and six to disease.

In my opinion these improved results may be attributed to the following causes: typhoid prophylaxis, the systematizing of sanitary effort in the army as inaugurated at the San Antonio camp two years ago, the increasing knowledge of officers and men of the benefits to be derived from sanitary measures and their consequent cooperation with the medical officers, the thorough support given the sanitary department by the commanding general and the zeal and efficiency of the medical officers.

With certain modifications in detail the sanitary measures herein outlined could be quite largely employed by the civil population in small towns and rural communities.

A NEOSALVARSAN FATALITY

M. E. HAGERTY, M.D.
ST. LOUIS

A number of untoward accidents have followed the use of salvarsan and neosalvarsan since its introduction as a therapeutic agent. Editorial comment in The Journal[1] called attention to the dangers of the use of this remedy. The following case, which is hereby reported, is perhaps one of the most striking examples of what may happen following the injection of salvarsan, even under the most favorable circumstances, that is, in one who was not suffering from any serious organic lesions; and it is especially significant owing to its correspondence with a report of Wilhelm Wechselmann[2] and also that of Homer F. Swift,[3] of three almost identical cases.

History.—H. C., man, aged 29, with a history of primary chancre about five years before, had mercury and potassium iodid treatment for over two years. For past two years he had taken no treatment. Present treatment began on account of mental attitude of patient rather than from any objective symptoms.

Ophthalmic examination by Dr. W. E. Klokke showed spots before eyes and a blurring of vision. Vision, right eye, was 6/7.5, left eye 6/10: no improvement with lenses. Cornea and lens clear; eye-ground showed arteries small, some pallor and beginning dilatation of retinal veins. Left eye showed considerable cloudiness of retina; no contra-indication of salvarsan. Physical examination showed patient extremely well developed, heart and lungs normal, slight enlargement of liver and spleen and slight amount of arteriosclerosis. Urinalysis was negative to albumin and sugar. Specific gravity 1.022, reaction slightly acid.

Treatment.—Feb. 26, 1913, the patient received the first injection of neosalvarsan, 0.6 gm. intravenously. This was prepared in freshly distilled crystal water. The patient had no ill effects from this injection, not even nausea, headache, chill or other disturbances that frequently follow such an injection. He was seen every day for several days. The first twenty-four hours urine showed a trace of albumin, and the specific gravity was 1.025. The urine was normal after twenty-four hours. Three weeks later he was given 10 drops of saturated solution of potassium iodid three times daily for a period of two weeks. After one week without treatment, six weeks after first injection, eye examination showed decided improvement. Vision, right eye, 6/6, left eye 6/6. Ophthalmoscope showed retinal vessels of the right eye normal. Arteries of the left eye were small and the veins dilated, but cloudiness had practically disappeared; pallor was still present in areas. The heart and lungs were normal, liver and spleen slightly enlarged, and kidneys normal.

The second dose, 0.6 gm., same as the first, of neosalvarsan was given intravenously. Following this injection the patient rested about fifteen minutes, showing no ill effects whatever. He then started for his hotel, which was one-half block distant. After being gone about ten minutes he returned and collapsed in reception-room, just as he entered. His face was flushed, muscles tense, and he fell on the floor in a convulsive state. Respiration was difficult, and there was some bloody froth at the nose. Usual remedies were given, including 1/30 grain strychnin hypodermically, followed shortly by 1/150 grain atropin and ¼ grain morphin. Muscles relaxed, breathing became easier, and consciousness was regained. The patient was placed on a couch and a little whisky and aromatic spirits of ammonia were given. Cyanosis cleared up, pulse came down fom 138 to 100; ambulance was called, patient walked to this unassisted. He was taken to the hospital and a special nurse put in charge. Heat was applied, and from that time he seemed to be all right; he complained of being tired, and rested for about five hours, then suddenly, without premonitory symptoms, breathing and heart action seemed to stop and the patient died, there being no final convulsions.

This is the first fatality occurring to me in over six hundred injections of salvarsan, but is the seventh death to my knowledge resulting from salvarsan in St. Louis since its introduction as a therapeutic agent.

The pathologic report of Dr. R. L. Thompson follows:

PATHOLOGIC REPORT, R. L. THOMPSON, M.D., ST. LOUIS

Body of well-developed and well-nourished male. Slight abrasion over bridge of nose. Pupils 4 mm. in diameter. Some froth exudes from mouth and nostrils; the latter being blood-tinged. Teeth tightly set. Lividity extreme over dependent portions of body and also well-marked on sides of chest, neck and head.

Abdominal cavity: Normal save for about 30 c.c. of slightly blood-tinged fluid in right hypochondrium. Peritoneum, normal. The superficial vessels of the stomach and duodenum show moderate congestion.

Pleural cavities: Normal.

Lungs: Voluminous, fill cavities; grayish-pink with usual carbon tracery. Pleura smooth. Bronchi intensely reddened and contain stiff slightly blood-stained foam. On section both lungs exhibit the most intense edema and congestion; blood and frothy fluid flow freely on slight pressure. The right lower lobe is especially firm and one of the medium-sized vessels is occluded by a red thrombus at the end of which is a small area of infarction about 2 cm. in diameter. There is more or less hemorrhage into the lung, surrounding this area.

Pericardial cavity: This contains about 20 c.c. clear straw-colored fluid.

Heart: The right side of the heart is dilated and filled with cruor clot. Heart muscle firm and dark red. Valves normal.

Arteries: Moderate fatty degeneration of intima of aorta most marked just above the aortic valve.

Stomach: Normal size. Contains about a pint of brownish-colored fluid of no particular odor. The mucosa is intensely reddened especially in the upper half and along the lesser curvature. This reddening appears as numerous tiny close-set ecchymotic dots. In addition a considerable amount of tenacious blood-stained mucus adheres to the stomach wall.

Intestines: The intestinal mucosa is practically normal, save for a slight congestion of the duodenum.

Pancreas: Congestion.

Liver: Slightly enlarged; surface smooth; on section dark red; blood flows freely from cut vessels; consistence slightly diminished.

Kidneys: Normal size; dark red. Capsule strips easily, leaving smooth surface. On section show intense congestion of both cortex and medulla.

Spleen: Somewhat larger than normal. Soft. On section dark red; pulp is semifluid in consistence.

Genitalia: Normal.

Scalp and skull: Normal.

Brain: Sinuses filled with dark fluid blood. Vessels of pia deeply injected; dark red; fine stellate markings of congestion, particularly well marked over occipital region. There is very little cerebrospinal fluid. The brain is heavy

and shows on section edema of the substance and congestion; puncta cruenta show marked spreading. The basal ganglia are quite dark in color, as is also the cerebellum, and blood flows on section of vessels of any size. The floors of the lateral ventricles and fourth ventricle show granular ependymitis. Pons and medulla normal. Spinal cord normal at cervical segment.

Thyroid, adrenals and pituitary: These all show intense congestion.

Anatomic Diagnosis.—Edema and congestion of lungs; small infarct, right lower lobe; acute gastritis; edema and congestion of brain; acute congestion of all parenchymatous organs and ductless glands.

Cause of death: Acute arsenic poisoning.

Thanks are due Dr. Louis R. Padberg, Coroner of St. Louis, for permission to publish the post-mortem report in this case.

THE EMPLOYMENT OF CARMIN IN GASTRO-INTESTINAL DIAGNOSIS *

SEYMOUR BASCH, M.D.
Adjunct Attending Physician, Lebanon Hospital
NEW YORK

Notwithstanding its comparatively long employment in gastro-intestinal diagnosis, the utilization of carmin for this purpose appears to be but little known and understood by the profession in general.

The employment of carmin in gastro-intestinal diagnosis is not new. As far back as 1874, Grützner[1] devised his colorimetric method for pepsin determination by carmin-stained fibrin, a method which has now merely a historical interest. For use in diagnosis, carmin may be taken in capsules, dry on the tongue, or mixed with water or food. When pure, it is absolutely harmless in moderate amounts. I have repeatedly administered as much as half a teaspoonful to patients and noted no bad effects. Schmidt[2] mentions that it may prove slightly irritating to the bowels, but this has not been my experience. Taken by mouth, the drug stains the feces, with which it becomes intimately mixed, a brick-red. The intensity and extent of this color is roughly proportionate to the amount of carmin taken, the rapidity of its passage through the gastro-intestinal canal and the consistency of the bowel contents. Carmin is probably not absorbed, as it imparts no stain to the urine, sweat, saliva, tears or visible tissues.

Carmin is used in gastro-intestinal diagnosis:

1. To mark off or differentiate the stools of one diet from those of another.
2. To estimate the rapidity of gastro-intestinal motility.

Following the suggestion of Adolf Schmidt[3], I have since 1899 made use of carmin in stool observations.[4] I find 5 grains a sufficient dose for ordinary purposes. This amount usually secures two distinctly red movements. The second, however, may have only a faint tinge in parts, or may contain but a few crystals of carmin. Large doses should not be given; they only prolong the red effect on the dejecta. I have the patient take the drug mixed with a teaspoonful of water.

The second-named purpose, that of estimating the rapidity of gastro-intestinal motility, has been described by Adolf Schmidt[2] and Spivak[5]. We have no means of determining the rapidity of the individual intestinal segments excepting by the Roentgen rays. When it is not possible to employ the Roentgen rays, we can gain an idea of the rapidity of the passage of food through the entire bowel in one of two ways. We can either introduce a carmin solution directly into the duodenum and time its exact exit per anum, or we can let the patient swallow the drug and, having estimated the motility of the stomach, deduct that time from the total time required for the first appearance of the red stools.

It may also be mentioned that carmin has been used in experimental demonstration in animals of the *Schichtung* or layer formation of the gastric contents during active digestion.

I wish to suggest the following additional uses of carmin in diagnosis:

1. To determine whether the alimentary canal is patent or obstructed and whether an existing obstruction is temporary or permanent.
2. To detect a fistulous communication with the alimentary canal.
3. To ascertain in a very simple manner if a duodenal tube is within the duodenum or the stomach.
4. To aid in the diagnosis of esophageal dilatation and diverticulum.

I have employed carmin repeatedly for the first three purposes named and can well recommend it for simplicity of use and accuracy of conclusions.

In the absence of vomiting, failure to reappear at all can be due only to complete obstruction (acute or chronic) somewhere in the digestive tract.

I would particularly suggest its employment in suspected infantile or so-called congenital pyloric stenosis. It has been shown by Nobécourt and Merklin[6] that in normal infants up to 3 months of age, red stools appear in from three to nine hours after the administration of 1 grain of carmin. Hence the complete absence of carmin excretion in these little patients would be indicative of a definite anatomic obstruction somewhere within the alimentary canal.

When the Roentgen-ray or instrumental methods cannot be used, the administration of a few grains of carmin, with a little water or nourishment, brings no added danger or inconvenience to the patient and may throw a flood of light on the situation.

In those cases of intestinal obstruction in which fecal contents still pass out, but come from points below the site of the obstruction, the special value of the carmin test is seen. If one of these patients be given carmin and the stools continue to appear unstained by the dye, the fact of a complete obstruction is absolutely proved.

The value of carmin in the detection of externally communicating fistulas is well illustrated by the following case, in which the patient was under my care in 1900:

Mr. A. C., aged 43, gave a history of pain in the abdomen, constipation and occasional blood mixed with the stools. The urine was turbid and there were pains before micturition. Physical examination was negative, but repeated examination of the freshly voided urine gave the following; Acid reaction, very turbid appearance, but no special odor. The microscopic examination of the sediment showed erythrocytes, pus cells and many transversely striated muscle fibers.

The last-named finding could only result from an intravesicular rhabdomyoma or from a fistulous communication between the bladder and bowel. To clear up the diagnosis, the patient was placed on a meat-free diet and given 5 grains of carmin. Soon he passed a very red urine that contained carmin crystals, but no longer any muscle fibers. This proved conclusively the absence of a rhabdomyoma and the existence of an intravesicular fistula. A positive diagnosis of a malignant intestinal tumor with a fistulous communication into the bladder was made. The case came to operation and proved to be an inoperable lymphosarcoma of the ileum adherent to and rupturing the bladder. A later post-mortem examination confirmed all the findings given.

In duodenal intubation and feeding it is important to know whether the distal end of the tube lies within the duodenum or stomach. It is not always possible to obtain secretion by suction, and when the secretion is of a golden yellow color and gives a strong Congo reaction, it may come from either the stomach or the first portion of the duodenum. The question can readily be settled by allowing the patient to drink a small amount of clear, fresh, watery solution of carmin and, attaching the feeding syringe, at once making suction. If the distal end of the tube is within the stomach, carmin solution will be withdrawn; if in the duodenum, no fluid at all, or characteristic bile-colored duodenal fluid, will appear.

Although roentgenoscopy is by far the best method for the diagnosis and differential diagnosis of esophageal dilatation and diverticulum, the suggestion is made that carmin be used in this connection in the same manner as some of the more or less distinctly colored food fluids (black coffee, milk, etc.), heretofore employed for this purpose. It has the special advantages of being bland, acceptable to all palates and of not changing its physical or chemical properties.

CONCLUSION

I would state that in the carmin test we have a simple, harmless, reliable and convenient means for the demarcation of stools, the estimation of gastro-intestinal motility and patency, for the detection of fistulous communications of the alimentary canal with the exterior or with other hollow organs, for the location of the distal end of a duodenal tube and to aid in the differentiation between esophageal diverticulum and dilatation.

With the more universal employment of this method, no doubt further fields of usefulness will suggest themselves.

A CASE OF BRAIN SYPHILIS

Nathan B. Eddy, M.D., New York

The course of the case of brain syphilis previously reported by me[1] has been interesting and for correctness a further report is necessary.

Previous History.—The previous report stated that the patient, F. M., aged 34, married, a laborer, having a positive syphilitic history, was admitted to the hospital Dec. 28, 1912, in coma with convulsions and a transient left-sided hemiplegia. He had a strongly positive Wassermann and was treated by repeated injections of salvarsan, neosalvarsan and mercury salicylate. For the time being his recovery was complete and on Feb. 8, 1913, he was discharged from the hospital, apparently in perfect health. During February and the first part of March the patient returned weekly for intramuscular injections of mercury salicylate, one grain being injected each time. About the first of March he went to work in an iron foundry.

Second Attack.—April 14, 1913, while at work, he suddenly fell to the ground in a general convulsion, which was followed by deep coma, and at 9:40 a. m. of the same day he was readmitted to the hospital. His condition was much the same as on his previous admission except that no sign of paralysis was present. He could not be roused. The pupils were equal and regular, though small and inactive. The pulse was full but not rapid and without high tension. All reflexes were diminished, those on the right side slightly more than those on the left. Otherwise physical examination was negative.

Because of the previous history the patient was given neosalvarsan, 0.9 gm., intramuscularly, the same afternoon. The blood and spinal fluid taken the same day were examined and both gave a strong Wassermann reaction. As before, recovery was prompt and continuous so that the patient was rational and comfortable, April 24, and was up and about, May 4.

The injection of neosalvarsan, 0.9 gm., was repeated, April 28, and the patient received the weekly injections of mercury salicylate as well as potassium iodid up to 90 grains three times a day. May 9, the patient felt so well that he insisted on going home, promising to return every week for injections. He was seen but once about two weeks later. At that time he was at work, though he seemed restless and rather silly.

Third Attack.—June 25, 1913, following excessive alcoholic indulgence, the patient was again seized with convulsions and was brought to the hospital at 12:30 p. m. He had a severe general convulsion shortly after admission. He was in coma with no sign of paralysis, and as before the coma cleared up rapidly, leaving him violent and noisy.

He was given salvarsan, 0.3 gm., intravenously, July 3, with only slight change in his mental condition, and mercury salicylate, ½ grain, intramuscularly, July 5, 9, 12, 16, 19 and 23. A Wassermann reaction, July 7, was strongly positive and a Wassermann reaction on the spinal fluid the next day was equally positive. A cell-count of the spinal fluid at this time showed 105 cells per cubic millimeter, the majority of which were epithelial cells with very few polynuclears. The fluid was perfectly clear and under pressure. The condition of the patient resembled alcoholic delirium, and varied from day to day from silly docility to noisy violence, but at no time was he rational. He had one more convulsion at 5 p. m., June 30.

Repeated examinations of the urine were entirely negative in result, showing no apparent effect on the kidneys of the many injections of salvarsan and mercury. His temperature was generally flat normal with an occasional rise to 99 or 100 F.

July 23 his temperature rose abruptly to 104 F. and his condition became much worse. He was drowsy and stupid and took fluids with difficulty. July 24 his temperature rose to 106 F. There were neither convulsions nor signs of paralysis. He became rapidly weaker and died in coma the next day, July 25, at 11:30 a. m. Necropsy was refused.

This case brings out the prompt response of a patient to strong antisyphilitic treatment in an undoubted case of brain syphilis, but the equally prompt relapse, increasing in severity following each interruption of treatment. At the same time I think there is no doubt that the patient's life was prolonged six months, a part of which time he was able to work, and much more might have been done had it been possible to keep him constantly under treatment.

A METHOD FOR ASEPTIC URETERAL CATHETERIZATION

W. P. Willard, M.D., San Francisco
Instructor in Urology, University of California

The sterilizing and aseptic handling of ureteral catheters has always been more or less of a problem to the cystoscopist. The method that I here present is one that I have used lately and have found simple and efficient.

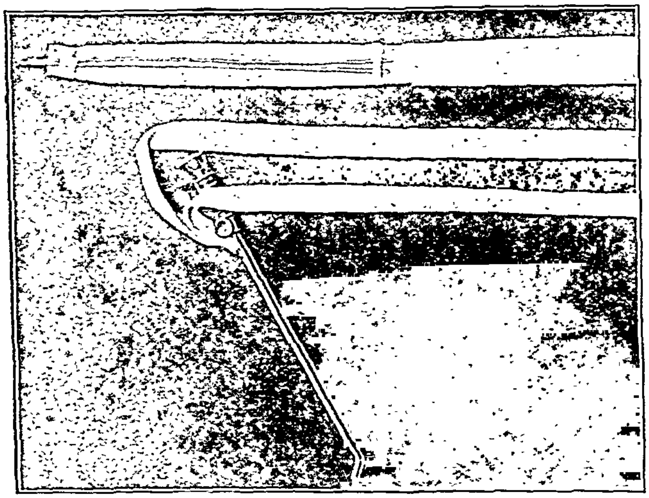
The boiling or immersion of the catheters in various solutions renders them soft and difficult to handle. Formaldehyd as it is generally used is not reliable. With a sterile catheter that is not protected it is almost impossible to avoid contamination of the long free portion. It is also very difficult for the cystoscopist to keep his hands clean, as the connection and switch cannot be sterilized and the handling of the catheter with forceps or gauze is difficult.

---

[1] Eddy, Nathan B.: Recovery in Brain Syphilis after the Use of Salvarsan, The Journal A. M. A., April 26, 1913, p. 1296.

I have bags made of muslin 2 cm. wide and about 75 cm. long. It is important to have them wide enough so that the bags fold up readily as the catheter is pushed forward. The catheter containing the wire is placed in the bag. The bag is then wrapped in paraffin paper and fastened in several places with adhesive strips. If a piece of wood is fastened on the outside of the paper at the tip end of the catheter, bending of the tip is prevented. It is well to mark on the paper the size and style of the catheter. The package is now placed in an autoclave for twenty minutes with a pressure of 8 or 10 pounds. A number of catheters can be sterilized at the same time and can be kept for an indefinite period without injuring them.

When the cystoscopist is ready to use a catheter the paper is torn off and the wire is removed. The tip is worked out of the bag and introduced into the cystoscope and pushed forward by holding the catheter through the bag. The instrument is introduced and the catheter manipulated through the bag. When the catheter is in the desired position the bag can be slipped off and the instrument removed.



A device for aseptic ureteral catheterization.

After a catheter is used it should be washed inside and outside and dried by forcing air through it and hanging it near a radiator or in the sun.

If the bag becomes wet during catheterization the wet cloth is apt to adhere to the catheter. The washers on the cystoscope should be tight. Care must also be used in handling the cystoscope containing the catheters to prevent the bags slipping down on the catheters. To keep the bag in place an elastic band can be placed around the bag after it has been pushed up on the catheter tube.

177 Post Street.

A Bouquet for the Doctor.—There is no other profession, unless we except the service of the church, which throughout its history has dispensed so much practical charity and given so much gratuitous service to the cause of humanity. There is no other that has maintained a higher code of ethics or one more scrupulously adhered to. There is no other that places so great and arduous responsibilities on its practitioners. There is scarcely another that requires such exacting training or such careful and continuous amplification of scientific equipment. The medical man who conscientiously meets the many and exacting requirements of his vocation has little time or opportunity for an avocation.—Corwin and Mayo, in *The Outlook*.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

ACNE VACCINE (See N. N. R., 1913, p. 221).

The Abbott Laboratories (The Abbott Alkaloidal Co.), Chicago.

Acne Bacterin Polyvalent.—Marketed in packages of six ampules, each containing 50,000,000 killed Bacillus Acne.

BACILLUS COLI VACCINE (See N. N. R, 1913, p. 221).

The Abbott Laboratories (The Abbott Alkaloidal Co.), Chicago.

Coli-Bacterin Polyvalent.—Marketed in packages of six ampules, each containing 100,000,000 killed Bacillus Coli Communis.

FRIEDLANDER VACCINE (See N. N. R., 1913, p. 222).

The Abbott Laboratories (The Abbott Alkaloidal Co.), Chicago.

Friedlander-Bacterin Polyvalent.—Marketed in packages of six ampules, each containing 100,000,000 killed Friedlander bacilli.

GONOCOCCUS VACCINE (See N. N. R., 1913, p. 223).

The Abbott Laboratories (The Abbott Alkaloidal Co.), Chicago.

Gonococcus-Bacterin Polyvalent.—Marketed in packages of six ampules, each containing 100,000,000 killed Gonococci.

PNEUMOCOCCUS VACCINE (See N. N. R., 1913, p. 224).

The Abbott Laboratories (The Abbott Alkaloidal Co.), Chicago.

Pneumo-Bacterin Polyvalent.—Marketed in packages of six ampules, each containing 100,000,000 killed Pneumococci.

MIXED VACCINES (See N. N. R., 1913, p. 224).

The Abbott Laboratories (The Abbott Alkaloidal Co.), Chicago.

Staphylo-Acne-Bacterin Polyvalent.—Marketed in packages of six ampules, each containing 500,000,000 Staphylococci, and 50,000,000 Acne Bacilli. Total 550,000,000 killed bacteria.

STAPHYLOCOCCUS VACCINES (See N. N. R., 1913, p. 225).

The Abbott Laboratories (The Abbott Alkaloidal Co.), Chicago.

Staphylo-Albus-Bacterin Polyvalent.—Marketed in packages of six ampules, each containing 200,000,000 killed Staphylococcus Albus.

Staphylo-Aureus-Bacterin Polyvalent.—Marketed in packages of six ampules, each containing 200,000,000 killed Staphylococcus Aureus.

Staphylo-Bacterins (Human) Albus—Aureus—Citreus.—Marketed in packages of six ampules, each containing 200,000,000 killed bacteria.

STREPTOCOCCUS VACCINES (See N. N. R., 1913, p. 226).

The Abbott Laboratories (The Abbott Alkaloidal Co.), Chicago.

Strepto-Bacterins (Human).—Marketed in packages of six ampules, each containing 200,000,000 killed bacteria.

TYPHOID VACCINE (See N. N. R., 1913, p. 227).

The Abbott Laboratories (The Abbott Alkaloidal Co.), Chicago.

Typho-Bacterin Polyvalent.—Marketed in packages of six ampules, each containing 200,000,000 killed Typhoid Bacilli.

Typhoid Prophylactic.—Marketed in packages of three ampules, each containing respectively 500,000,000, 1,000,000,000 and 1,000,000,000 killed bacteria.

SATURDAY, OCTOBER 4, 1913

THE EFFECT OF FOOD ON METABOLISM

Under ordinary conditions of life, and in the absence of modifying pathologic factors like fever, metabolism may be increased by two prominent causes. One of these is muscular activity, which is also commonly referred to by the terms "work" and "exercise." The other factor is the ingestion of food. Extremes of external temperature are, of course, also not without influence on metabolism; but in every-day experience they are modified or counteracted by numerous environmental agencies, such as variations in clothing, etc., so that this element in the forces which play on the energy transformations in our bodies will here be left out of consideration.

The heightened metabolism following the intake of food is not characteristic of any group of foodstuffs in particular, but is evoked by proteins, fats and carbohydrates, though in widely different degrees. It is greatest in the case of proteins. Why muscular work should stimulate the metabolic activities is evident: the problem is merely that of the transformation of energy from one form into another—of converting body fuel into muscular contractions. But why the mere ingestion of food in a person at complete rest should excite a conversion of energy beyond what the basal requirement of the resting individual demands has been a puzzling question for physiologists. There have been two prominent "schools" of opinion. Zuntz and his co-workers assume that the increase in metabolism after eating is mainly due to the mechanical processes of digestion, including the work of peristalsis, segmentation, absorption and glandular activity. The eminent Berlin physiologist Rubner, on the other hand, attributes the increased conversion of energy to what he has termed the "specific dynamic action" of the foodstuffs; that is, they exert an obscure influence whereby part of the energy appears as free heat and does not benefit the cells. On the one theory, as we see, the increase in metabolism is charged chiefly to mechanical causes; on the other, it is mainly attributed to chemical processes.

We have touched on these questions before, and it seems worth while to recur to them whenever fresh evidence bearing on the controversy is presented, for everything pertaining to the theory of metabolism sooner or later finds its application in the experiences and practices of nutrition. Drs. Benedict and Pratt[1] of Boston, have followed the ingenious plan of determining how the metabolism is affected by interference with some of the alimentary factors held by the advocates to be so important for the exhibition of the increased metabolism following the ingestion of food. They have made a study of the metabolic changes entailed by feeding meat to dogs without (external) pancreatic secretion. When the latter is diverted from the digestive tract by surgical interference, for instance, by ligation of the pancreatic ducts, the power to digest and absorb proteins is well known to be greatly impaired. It was evident, therefore, that under these circumstances there would be a maximum work of digestion so far as peristalsis and segmentation are concerned, and a decreased absorption of material from the foodstuffs to be carried by the blood to the cells, there, according to Rubner's views, in part to produce free unutilized heat. It was believed, therefore, that a study of the metabolism of these animals to determine the effect of ingesting meat would throw light on the general question of the cause of the increased metabolism following the ingestion of food.

Despite the mechanical work required to pass the enormous masses of unabsorbed food through the intestinal tract, the postprandial increase in metabolism in the experimental animals was decidedly below rather than above what is found under the same conditions in normal animals. This outcome does not support the hypothesis of "digestive work" as a cause of heightened metabolism. The results show that there is no large energy transformation incidental to segmentation, peristalsis, glandular activity of stomach, liver and intestine, and the movements of the unabsorbed food through the intestinal tract. The attempt to explain the increased metabolism following the ingestion of food by the theory that the increase is a consequence of such movements, is, therefore, not justifiable. Thus the theory of a special action of the products of digestion on the metabolism of the cells is gaining ground through the accumulation of evidence.

HORSES, WOMEN AND CHILDREN

Last Decoration Day, in addition to the customary parades, there were parades of workhorses in which many of the horses wore at their heads the blue, red and yellow ribbons bestowed in recognition of the care and merciful treatment given them by their owners. The latter parades also typified an emancipation—that of the defenseless horse from the overloading, the lashing, the cursing and the rough treatment resulting in sores and bleeding mouths prevalent not many years ago. The change has been brought about by a propaganda against cruelty to horses which has been so effective that now not only are drivers humane in their treatment of these faithful servants, but a genuine pride is taken by owners in keeping their horses sleek-coated, with neatly combed manes and tails, superbly harnessed to handsome trucks and, above all, adequately nourished.

---

[1] Benedict, F. J., and Pratt, J. H.: The Metabolism after Meat Feeding of Dogs in Which the Pancreatic External Secretion Was Absent, Jour. Biol. Chem., 1913, xv, 1.

Formerly drivers said that they must work their horses to the limit of every ounce of horse-power or that competitors would distance them by doing so. The propaganda which has been carried on for a decade or more has demonstrated that a mercifully treated horse is an economic advantage, because, though more work may be obtained for a brief space from a hard-driven horse, his earlier death ends surely in business loss. So now there is a wholesome tendency among those who own and use workhorses to discourage cruelty. It seems as though the tragedy of the misused horse were passing into history.

Employers of women and children in factory and sweat-shop are beginning to see the same light. Contractors have explained that they must drive thin-blooded, hollow-eyed, consumptive women to death, and employ children not much more than weaned, because of the fierce and utterly merciless competition between manufacturers; but the idea is gradually gaining ground that such doings are an economic mistake and altogether too expensive to indulge in. Besides, the growing social sense of the degradation of those who blood-sweat women and little children causes ostracism, which is hurtful to the pride. The propaganda against these things, which is carried on by such enlightening and discriminating agencies as the American Consumers' League, is doing much to force the public to realize too that "the poverty of Lazarus makes itself felt in the house of Dives"—through infection-ridden garments conveyed from the sweat-shop,[1] and from the bargain counter, to the family of the purchaser; and of course that kind of thing does not pay at all. Humanitarians are seeking and obtaining legislation in behalf of the human weakling. So, as the slave has been emancipated, and to a large extent, the horse, it really seems that the tragedy of the defenseless woman and child will, within a few years, also pass into history.

CHEMICAL SIMILARITIES AND BIOLOGIC DIFFERENCES

The recent trend of biologic investigation is tending, in a way, to upset many of the older notions regarding the uniform make-up of the animal tissues. There was a time when the chemical components of blood, for example, were assumed to be essentially alike in all related forms. Blood proteins, muscle proteins and, indeed, tissue proteins in general were believed to have a close similarity which expressed itself in comparable solubilities and physical properties. Thus it came about that such distinctive terms as "albumin" and "globulin" were introduced to designate variations in the behavior of the proteins toward different solvents; whereas there seemed to be no impelling reason to doubt that, broadly speaking, the globulins or albumins of different sources resemble each other closely. Indeed, the belief began to assert itself that the proteins of plant sources also could be put into the same category with the albuminous products of animal origin in so far as they exhibited comparable solubilities.

It has remained for the modern development of what is called immunology to bring out forcibly the incisive fact of marked physiologic differences between proteins of apparently similar properties, using the latter term in its common acceptance of behavior to ordinary reagent tests. The more subtle biologic examination has demonstrated the remarkable specificity of all the individual products of similar or related character. When chemical analysis has not been able to point to distinguishing characteristics, even when it has been carried to the refinement of technic represented by the most up-to-date methods of Emil Fischer and his followers, biologic tests in the field of immunity reactions—the phenomena of the precipitins, anaphylaxis, etc.—have still been able to emphasize the undoubted distinctive features of even such apparently comparable products as the chemically similar proteins of the blood of two animal species.

Even along distinctly chemical lines, however, dissimilarities are beginning to crop out where they were formerly scarcely expected. By way of illustration we may refer to recent investigations of the protein keratin, which forms the basis of hair and similar tegumentary substances. Data collected by Buchtala[1] show that human hair is distinguished among the various keratinous structures by its unusually high content of cystin-yielding components. Sulphur derivatives have long been described as abundant in hair and horny structures; but it is now accurately demonstrated that in addition to the usual amino-acids obtained by the decomposition of proteins in general, human hair may yield nearly 12 per cent. of the sulphur-containing derivative cystin. This unusual proportion differentiates it chemically from all other animal hair and also from the closely related wool of the sheep.

Such findings recall the contention of one of the foremost students of the chemistry of the proteins, T. B. Osborne,[2] that structural differences exist between very similar proteins of different origin; and it is interesting to note that chemically identical proteins apparently do not occur in animals or plants of different species, unless they are biologically very closely related. In this respect the proteins are in marked contrast to the other constituents of plants and animals, for not only do identically the same sugars and fats occur in many species of plants and animals, but many of these

---

---

[1] Buchtala, H.: Ueber das Keratin der weissen Menschenhaare, Ztschr. f. physiol. Chem., 1913, lxxxv, 246.

[2] Osborne, T. B.: Chemistry of the Proteins, Harvey Lectures for 1910-1911, Philadelphia, 1911, p. 72.

are common to both forms of life. It thus appears that the chemical constitution of the proteins is closely connected with the biologic relations of the forms of life which produce them, and that the morphologic differences between species find their counterpart in the protein constituents of their tissues.

THE SENSES OF TASTE AND SMELL

If asked to make a distinction between the sense of taste and that of smell, most of us would probably say that besides differences in the organs with which these manifestations are concerned, the stimuli which call their respective sensations into existence are unlike. It has generally been assumed and taught that taste is excited by substances in the state of solution and that smell is called forth by products in a gaseous or vaporous condition. This view, however, has not remained unchallenged. It has been contended by a number of physiologists that solutions may act as stimuli for the olfactory surfaces, and some have gone so far as to assert that in normal functioning of the sense of smell in man, the odorous particles are caught on the moist olfactory surfaces and dissolved before they can act on the nerve terminals.

The problem of these possible distinctions in the two senses has been taken up in an experimental way by G. H. Parker and Miss Stabler.[1] Selecting as a stimulus a substance—ethyl alcohol—which has both a characteristic odor and a well-marked taste, they have made some comparisons which lead them to conclude that in vertebrates the stimulus for smell is a substance dissolved in the fluids that bathe the olfactory surface, and that in this respect smell and taste are similar. The difficulty in imitating a normal stimulation of the olfactory organs by solutions experimentally introduced into the nose is due, in the opinion of Parker and Stabler, to the inability of the investigator to reproduce the olfactory solvent. This material, the slimy covering of the olfactory surface, is very different from water or even warmed physiologic salt solution. Hence it is not surprising that odorous substances dissolved in these mediums should not act as normal stimuli for the olfactory surfaces. Were it possible to imitate closely the olfactory solvent there might be no difficulty in stimulating the olfactory organs with solutions made up in this solvent.

Both smell and taste are, then, stimulated by solutions, but water introduced into the human nose will cause a temporary loss of the power of smell. Hence, the olfactory organs are not appropriately stimulated by ordinary aqueous solutions. Besides the possible different chemical nature of the stimuli, that for the sense of taste is a relatively strong solution, that for smell a relatively weak one. The bearing of these facts has been summarized by saying that we smell enormously attenuated solutions and taste only relatively strong ones. Taste is used in determining the presence of comparatively large amounts of substance, smell for only the most minute quantities. Hence, taste is inoperative except when the source is very near at hand, usually in the mouth; whereas smell may be active when the source is far distant, the dilution experienced by the stimulating substance in its spread not having been sufficient to bring it below the concentration necessary for stimulation.

Current Comment

THE CALL OF THE EMPTY STOMACH

If it be true, as was suggested in our recent discussion of the contractions of the stomach attending the sensation of hunger,[1] that the actual stimulus to these is inherent in some local gastric mechanism rather than in general systemic conditions, it might be expected that the hunger contractions would appear as soon as the stomach is empty of food or other substances capable of stimulating the mucosa. It is a physiologically advantageous arrangement whereby the inhibition of the hunger contractions by mechanical and chemical stimulation of the gastric membrane prevents the appearance of these contractions during the period of gastric digestion. It would not be strange, however, if psychic and other factors, such as habit, fatigue, etc., interfered in daily life with the expected manifestation of hunger immediately after the emptying of the stomach. As a matter of fact, most of us probably do not always experience the sensation of hunger at every period when the stomach is empty. There are too many distracting or inhibitory agencies playing on us. Carlson[2] has pointed out that we should look for the closest parallelism between the gastric hunger contractions and the absence of stimulation of the gastric mucosa in infants and young children, that is, before cerebral (and possibly gastric) habits relative to feeding have become established. He has noted precisely what might be anticipated under such uncomplicated conditions. Other things being equal, the more food put into the stomach, the longer the time required for the completion of gastric digestion. An infant given only four ounces of food exhibited phenomena of hunger, that is, called for more, after about two hours. When seven or eight ounces of the same food was furnished, the call for food was delayed for three or four hours. If the child was given a limited amount of food at bedtime it waked up much earlier than when the feeding was carried to the point of satiety. Carlson cites these observations as evidence of the close parallelism between the time of the emptying of the stomach and the appearance of the hunger contractions which initiate the sensation. He suggests that the more frequent calls for food during the day are obviously due to the fact that the gastric hunger contractions must reach a certain degree of intensity before they cause the soundly sleeping infant to wake up. Perhaps, after all, the sensation of hunger is a better guide to gastric conditions than has been admitted in the past, so that we ought to cultivate a familiarity with it more intelligently than is the custom among the majority of persons.

PRACTICAL VALUE OF PREVENTIVE MEDICINE—ANOTHER EXAMPLE

The benefits and practical value to human health of modern preventive medicine have again been well illustrated in the army camps which have been established in 1911 and 1913. Certainly the success attending the efforts of army sanitarians at these camps, or "mushroom cities," holds much of promise to the people of both town and country. Such disasters as those connected with the camps during the Spanish War need no longer be feared, and the parents of the young volunteer of future wars may be assured that if he is spared the bullets of the enemy he will not fall a sacrifice to his patriotism through ignorance of how to keep well—that is, provided recently discovered methods of preventive medicine are put into effect, as has been the case in recent camps. In the brief account which appears elsewhere in this issue, of the health conditions in the camp of the Second Division near Galveston, we read of a sanitary competence that is further removed from the insanitary camps of the Spanish War than were the latter from those of the middle ages. The truth is, however, that men are prone to forget lessons learned through long experience if not living under conditions constantly enforcing them. The Mosaic sanitary rules are not new, but those who grow up with no thought of water-supply or sewage disposal are usually helpless when thrown suddenly into a situation where these are not provided. Here the penalty of ignorance has been death. That the men in these camps were selected and of good physique does not make less remarkable the lesson of preparation read in the results of protection from the epidemic of contagious diseases to which such a group of men is liable. The explanation of the results, which include no typhoid or small-pox and but eighteen cases of malaria among twelve thousand men in five months, in a country where these diseases are frequent, is merely the utilization of sanitary methods within the reach of any of our communities, large or small. Just as remarkable is the fact that the average monthly number of cases of venereal diseases among these twelve thousand *men* is seventy. Preventive medicine applied to a receptive and intelligent population would seem to be a profitable investment for any community, even looking at the matter solely from the dollars-and-cents point of view.

MEDICAL ADVERTISING AND THE NEW ORLEANS *ITEM*

For years THE JOURNAL has maintained that practically all "patent medicine" advertising is fraudulent. This claim has been denied with various degrees of insistence by those interested directly or indirectly in the "patent medicine" business. The "patent medicine" men themselves have, of course, been the most outspoken in their denunciation of THE JOURNAL'S attitude in this matter and, in their attempt to offset the damaging proofs which have been submitted, have accused some of the officers of the Association of practically every crime in the calendar. Moreover, they have not hesitated to purchase those publications whose editorial pages were for sale for the purpose of directing a flood of verbal sewage against those responsible for THE JOURNAL'S policy. Less virulent, if not less dangerous to the public, were those newspapers that offered in their advertising pages a welcome haven to the "patent medicine" frauds and quacks. Even conservative and decent newspapers have held that THE JOURNAL'S attitude in this matter was extreme to the point of fanaticism. Nevertheless, THE JOURNAL'S propaganda is having its effect. One by one newspapers of the better class are adopting THE JOURNAL'S attitude toward the fraudulent "patent medicine." One of the latest of the great papers of the country to do this is the New Orleans *Item*, which, on October 1, put into effect a new set of rules governing the acceptance of medical advertising "copy" to its pages. These rules are reproduced in full in the Propaganda Department of this issue. They are worth reading. The *Item* has had this step under consideration for some months and enlisted the help of THE JOURNAL staff for suggestions regarding the rules it finally adopted. While the *Item*, under its new rules, will not reject all "patent medicine" advertising, it will reject both such as is plainly fraudulent and also such as it may find reasonable grounds to suspect after subjecting it to a most rigid scrutiny. As to the effect that these rules will have on the medical advertising previously carried by the *Item*, this is excellently expressed in a letter recently received from the managing editor. He writes: "Practically the whole business will go out on October 1. I am frank to say that I did not know how bad it was until I had it collected and began to look at it in a critical way." Yet it should be borne in mind that the New Orleans *Item* was no worse—in fact a great deal better—than many of the large metropolitan dailies. The admission, then, that under its new rules *practically* the whole business of medical advertising will go *out* is a sermon in itself. The rules, while excellent, are in *no* sense extreme. If their enforcement causes the rejection of practically all medical advertising copy, then the "patent medicine" business is all that THE JOURNAL has ever said it was—and more.

THE LOW COST OF DYING

This comment has nothing to do with medicine. The matter discussed concerns physicians only to the extent that members of the medical profession are among the leaders of thought in their respective localities. The newspapers of the country recently contained the following brief item of telegraphic news sent out by the Associated Press:

> New York. September 26.—Max Blanck, one of the proprietors of the Triangle Waist Company, whose building was swept by fire in March, 1911, with the loss of 140 lives, was found guilty to-day of having the doors of the factory fastened August 5 of this year. He was fined $20.

One hundred and forty young lives were sacrificed to a horrible and needless death. A heap of charred corpses just inside a bolted door told the gruesome story. But Max Blanck and his partner went free. Now he is arrested again for having his factory doors locked as they were locked on that awful day in March, 1911. This time Blanck is found guilty and fined twenty dollars! Those good conservative souls with ossified intellects who deplore the present social unrest and the signs of revolt among what we are pleased to call the "lower classes" might, if they would, find in such cases as these a possible explanation for the phenomenon that gives them such concern. Meanwhile, with Franklin P. Adams, in his "Cui Culpa?" we feel like saying:

Pray God we grow not bitter, but it makes the vision red—
This hellish truth of crushed-out youth, this tale of needless dead!
No single name shall bear the blame, go "probe" ye ne'er so deep,
For the Cost of Living rises high, but the cost of life is cheap.

THE NATURE OF THE URINE SUGAR IN PENTOSURIA

The occurrence of pentose in the urine under certain anomalous and little-understood conditions has been known more than twenty years since its presence was first discovered by Salkowski. For many years the precise nature of the five-carbon sugar actually excreted in pentosuria has been debated. Despite the growing number of cases which have been detected and have found their way into medical literature, there still is no unanimity on the chemical feature just referred to. So long as the exact chemical structure of the carbohydrate eliminated is not definitely determined there is little prospect of any satisfactory explanation of this rather unique perversion of metabolism. Until quite lately the view has prevailed that the excreted sugar of pentosuria is arabinose. Recently Elliott and Raper[1] suggested the possibility that the urine pentose sugar is ribose. This has now been further emphasized by new observations[2] leading to the same conclusion, though it is still admitted that perhaps more than one type of pentosuria may occur. From the point of view of tissue chemistry the appearance of ribose is more readily interpreted, since this pentose has been demonstrated to be a constituent fragment of some of the nucleic acids.

WHY MEDICAL ADVERTISING IS GENERALLY FRAUDULENT

At different times, we have been asked the question: Why is medical advertising usually fraudulent? This question has been answered to the best of our ability, but we have never answered it any better than does *Standard Advertising* in its issue of September, 1913. This magazine is carrying on a campaign for clean advertising. Here is its explanation:

"In the orderly working out of our campaign in favor of clean publications some criticism has come to light because, according to our notion, medical advertising is not legitimate.

"The contention that a doctor, or the owner of a proprietary remedy, may be as honest as a regular medical practitioner is true. He *may be*. But if he told the truth about his service he would make no advertising profit.

"No advertising doctor possesses any secret which the profession does not possess. He must make believe some unusual advantage or his advertising will not pull.

"Again, sick people are, as a rule, gullible. They are discouraged, disheartened, and in no condition to analyze. They grab at straws, and the main thing which medical advertisers do is to make the patient 'feel better' regardless of the permanent effect on the system.

"This brings about the 'dope' which is so much in evidence in advertised remedies and treatments.

"*Standard Advertising* has no criticism to make of any doctor simply because he advertises, but the facts stand out clearly that if he makes his offer in keeping with the truth he will not attract business, and for that reason medical advertising is at least 90 per cent. fake advertising."

CHILD LABOR IN GEORGIA

At least for another year 10-year-old children, who can neither read nor write, will lend their efforts to increasing the fortunes of the cotton-mill owners of Georgia. The Anderson bill, which raised the age limit for working children to 13 years for 1914 and provided for a further increase to 14 years in 1915, has been sidetracked in the legislature, and the session is about to close. Georgia has made practically no advances along this line since 1906. This is not creditable to the traditional chivalry and civilization of the South.

Medical News

ILLINOIS

Personal.—Dr. John H. Wedig, Granite City, was seriously burned on the face and hands September 12 when the engine of his automobile caught fire, destroying the machine.——Dr. J. A. Campbell, recently appointed superintendent of the Watertown Hospital, took charge September 14.——Hastings H. Hart has resigned as state superintendent of the Illinois Children's Home and Aid Society.——Dr. S. V. Balderston, Evanston, has resigned as commissioner of health.

Medical Society Refuses to Nominate Evanston Commissioner of Health.—The Evanston Branch of the Chicago Medical Society has declined to accede to the mayor's request for the nomination of a commissioner of health in view of the facts that the city is unable to remunerate adequately the service of a physician of the type required, and that the honor of the office has been lowered by placing the health department under control of a new officer, the director of public safety.

Prevention of Tuberculosis.—Peoria has passed an ordinance for the expenditure of $20,000 for a municipal tuberculosis hospital.——The La Salle County supervisors have appropriated $3,200 for a county sanatorium for tuberculosis patients. The La Salle County Anti-Tuberculosis League was organized at Ottawa, September 14. The following officers were elected: president, William Bedford, La Salle; vice-presidents, Drs. E. W. Weis, Ottawa; William Schoenneshofer, Lostant; Roy Sexton, Streator; E. P. Cole, Mendota; A. J. Weirick, Marseilles; Benjamin J. Nauman, Peru, and Fred Guthrie, La Salle.——The Lake County supervisors are expected to select a 10-acre tract of land near Waukegan for a tuberculosis colony.——The Illinois State Association for the Prevention of Tuberculosis will hold its annual meeting in connection with the meeting of the Illinois State Conference of Charities at Rockford, October 13.

Chicago

Personal.—Dr. W. J. Anderson has resigned as night warden of the county hospital.——The sixty-sixth anniversary of the birth of Dr. Alfred C. Cotton was celebrated, September 25, at the Hotel Sherman by a banquet given in his honor by his associates in the Chicago Medical Society, who presented him with a diamond-studded gold watch.——Dr. C. Volini has been

---

1. Elliott and Raper: Jour. Biol. Chem., 1912, xi, 211.

2. Levene, P. A., and LaForge, F. B.: Note on a Case of Pentosuria, Jour. Biol. Chem., 1913, xv, 481.

appointed by Governor Dunne as member of the West Park commission.——Dr. William Wild has been appointed director of the Nebraska State bacteriologic and pathologic laboratory.

Relief Work for Tuberculous Children.—Trustees of the Municipal Tuberculosis Sanatorium have arranged to assist the Elizabeth McCormick Memorial fund with $7,000 for this season's work in open-air schools and other relief work for children affected with tuberculosis.

Tuberculosis Sanatorium to Be Built.—The cornerstone of the Sanatorium for Advanced Cases of Tuberculosis, which has a 10-acre tract at Fiftieth and Belmont avenues, will be laid October 19 under the auspices of the Jewish Consumptives' Relief Society, which is endeavoring to raise $50,000 for the new work. It is intended to make the institution one of the best in America.

INDIANA

New Officers.—Second District Medical Association at Washington: president, Dr. A. T. Custer, Linton; secretary, Dr. T. Roy Cook, Bloomfield.

Personal.—Dr. James B. Bobbitt, Indianapolis, has been appointed assistant surgeon in the Medical Reserve Corps of the United States Navy.——Dr. John S. Dukate, Alford, celebrated his ninetieth birthday anniversary September 21. ——Dr. A. G. Pohlman of the faculty of the Indiana University Medical Department has been elected head of the department of anatomy in St. Louis University.

Canvass for Hospital Funds.—The Methodist Episcopal Hospital, Indianapolis, on account of the enormous demand for rooms, has decided to build a new wing and also a nurses' home that will accommodate 100 nurses, and also provide additional facilities for labor work. At a recent meeting of the board of trustees, Hon. Charles W. Fairbanks was elected as chairman and teams were organized to raise $250,000 in a ten-day campaign.

Tuberculosis Notes.—The Floyd County Board of Commissioners, at a meeting in New Albany, denied the petition of the New Albany Anti-Tuberculosis Society for an appropriation of $20,000 or any other amount to establish a tuberculosis hospital in New Albany. The society has been offered a 40-acre tract of land on the knobs back of New Albany as a site for the proposed tuberculosis hospital, and will endeavor to raise $2,000 for the erection of an administration building. ——The business men of Portland have raised sufficient funds to erect a tuberculosis cottage on the Jay County fair grounds. This cottage will eventually be moved into the city and placed in charge of a trained nurse.

MARYLAND

Cooperative Purchasing Committee.—The Cooperative Purchasing Committee of the five state hospitals for the insane which has just been organized, will award bids for supplies for the five institutions for three months. This committee consists of the superintendent of each of the state institutions for the insane and has direct charge of the purchasing of all supplies.

Investigation of Trachoma.—Surgeon-General Herbert Harlan, a member of Governor Goldsborough's staff, will leave Baltimore shortly for Knott County, Kentucky, where he will begin an investigation of the prevalence and cause in that community of trachoma. Dr. Harlan will go under the direction of the Surgeon-General of the United States Public Health Service. He will outline a campaign to be carried on by the Knott County physicians.

Will Study Infectious Diseases.—Health Commissioner Gorter has gone to New York to inspect the health department of that city and to visit its hospital for minor infectious diseases, and will stop in Philadelphia for a similar purpose. He is seeking information to be used in designing a new ward building at Sydenham, to cost $30,000, and in planning quarters for the local health department. The building at Sydenham is to be for the treatment of measles.

Report on Tropical Diseases.—A complete report on tropical diseases prevalent in Ecuador and adjacent republics is being made to Superintendent Smith of Johns Hopkins Hospital, by Dr. A. W. Sellards of the Hopkins staff, who returned recently from an expedition to South America to study tropical ailments. Dr. Sellards was the representative of Johns Hopkins Hospital in the expedition sent out by the Harvard Medical School, under the direction of Dr. Richard P. Strong.

Medical College Opening.—So great was the rush for matriculation, that the lists for the coming term of the Johns Hopkins Medical School were closed two months ago and applicants have been turned away every day since. Ninety was the number set for each class, and when this number was reached, no more students were admitted. Practically all of the new students are from the United States; there being two from Canada, two from Scotland and one from China. There are seventy women among the four classes.

New Buildings for Hospitals.—Work has been commenced on the John Hubner Psychiatric Hospital at the Springfield State Hospital. The construction and equipment of this building will cost about $150,000. It is to be used as a reception hospital and is well equipped with all modern facilities for the study and treatment of mental cases.——Contracts have been awarded and ground broken for the first of a series of buildings for the Eastern Shore State Hospital for the Insane at Cambridge. It is expected that the building will be completed by spring for the reception of at least 200 patients.—— A new cottage for private patients has just been completed at the Relay Sanitarium.

MINNESOTA

Reorganization of Minneapolis City Hospital Staff.—The reorganization of the Minneapolis City Hospital staff has been completed, the staff being divided into two groups, the first composed of men on the medical staff of the University of Minnesota, and the second group of men not on the university staff.

University Clinics to Be Continued at St. Paul City and County Hospital.—The controversy between the University of Minnesota medical school and the board of control of the City and County Hospital has been satisfactorily adjusted, the board approving the appointment of the university staff surgeons and physicians recommended by President Vincent and continuing the clinics at the hospital.

Measures Against Tuberculosis.—The county commissioners of Hennepin County, in which Minneapolis is located, have tentatively appropriated $50,000 for a county tuberculosis hospital, for which the state will donate $50,000 and pay $5 a week for the care of each patient.——The new tuberculosis sanatorium of Otter Tail County, built at Otter Tail Lake, will be ready to receive patients by October 10.——The county commissioners of Lyon County have appropriated $6,000 to establish and maintain a tuberculosis sanatorium, provided that at least three other counties shall contribute their share toward the cost of such a sanatorium.

NEW YORK

New York City

Opening of College of Physicians and Surgeons.—The College of Physicians and Surgeons of Columbia University held its opening exercises on the morning of September 24, at which time Dr. George E. Brewer, professor of clinical surgery, made the opening address on "Standards of Success in the Practice of Medicine."

Course in Sex Hygiene for Teachers.—It is announced that New York University has established a course in sex hygiene for students in the school of pedagogy. The course will consist of ten one-hour lectures. The lecturers appointed for this course are Dr. Edward L. Keyes, Jr., Dr. Rosalie Slaughter Morton and Thomas M. Balliet, Ph.D., dean of the school of pedagogy of New York University.

Milk Stations End Twenty-Second Year.—The infant milk stations founded and maintained by Nathan Straus have completed their twenty-second year. There are now eighteen of these stations in Manhattan and the output during the past year was 2,193,210 bottles of pasteurized milk and 1,545,419 glasses of milk were served from the booths. During the past twenty-two years 35,000,000 bottles of pasteurized milk have been served to the babies of Manhattan. The output for the first year, 1892, was 34 000 bottles.

Special Classes for Stutterers.—The Board of Superintendents of the Board of Education has issued special instructions for parents and children for the cure of stuttering. They state that the public schools are proving day by day that the habit of stuttering can be cured. A speech-improvement class has been formed and parents are urged to see that children afflicted with stuttering seek admittance. Parents are instructed as to the methods that they may use in order to cooperate with the school and to supplement the work of the school class.

Personal.—Dr. Charles F. Bolduan has been appointed lecturer on hygiene and sanitation in the medical department of New York University.——Dr. Walter Bensel is to be retired as sanitary superintendent of the Board of Health on October 1, under the law which permits retirement at the end of twenty years' service at a pension not to exceed one-half salary.——Dr. Walter Mendelson has been named the fourth alumni member to succeed the late J. Pierpont Morgan in the board of trustees of Columbia University. Dr. Mendelson is the first alumni member of the board to be chosen from the College of Physicians and Surgeons.——Dr. John W. Dowling, while making a professional visit in Easton, Pa., was stricken with apoplexy and is lying in a serious condition at the Easton Sanatorium.

Typhoid Outbreak Checked.—It is stated that the typhoid epidemic on the East Side is now well in hand and that the number of cases reported is rapidly decreasing. From September 3 to September 25 there were 271 cases reported on the East Side from the Battery to Fortieth Street, while the number of cases reported from other parts of the city was below normal. This outbreak is pointed to as a lesson against the use for drinking purposes of any milk other than that designated as "Grade A" or of pasteurized milk that has been carefully guarded against contamination after it has been pasteurized. Dr. Lederle has expressed the opinion that antityphoid vaccination, if made compulsory as vaccination against small-pox now is, would make such an epidemic impossible, but he does not think that the public is educated to the point where such a step would be practical.

Improvements at the Otisville Sanatorium.—A new shack which will accommodate twenty-four children has recently been opened at this institution and it is hoped that two new pavilions for women which are in the process of construction will be ready for occupancy within a few weeks. These additions will provide for 100 patients and will bring the total capacity of the institution up to 600. The corporate stock budget recently passed provides among other things funds for the construction of a staff house and a nurses' home, and $75,000 has been made available as a general building fund, part of which will be used in constructing additional pavilions for both men and women. Early in the present year a number of the patients were treated by means of artificial pneumothorax, and up to date some twenty have been treated by this method. The results obtained have been quite generally encouraging.

Food Inspection.—For the purpose of guarding the city's food supply a laboratory of eight chemists and seven technical assistants is employed, together with four bacteriologists and ten assistants. During the year 1912 nearly 24,000,000 pounds of meat, fruit, eggs, fish and other foods were condemned and destroyed. There were 423,732 separate inspections made of premises where meat and other foods were handled and sold. Of 1,409 samples of food procured for anaylsis 421 were found adulterated. During the year 2,260 arrests were made by the Division of Food Inspection and in 1,911 cases fines to the amount of $14,070 were imposed by the courts. During the first six months of 1913 fines to the amount of $10,923 had been obtained. These figures were exclusive of milk inspection. There were 41,292 inspections of dairies, and 19,577 quarts of adulterated milk were destroyed, 1,763 arrests made, and $11,397 was collected in fines.

NORTH CAROLINA

Malaria Prevention.—Surgeon Henry R. Carter, U. S. P. H. S., accompanied by Dr. John C. Rodman of Washington, N. C. (local U. S. P. H. S. officer) has just returned to his station after visiting a number of eastern Carolina towns and holding public meetings in the interest of increased professional and public activity in the prevention of malaria.

New Staff Provisions.—Following recent consultations of the advisory board and the active board of managers of the Mission Hospital at Asheville, and growing out of the manifest professional dissatisfaction of having a public hospital with a permanent and non-rotating staff it is officially announced that, beginning with the annual election in November, three new members will be added to the staff biennially. In this way a portion of the staff at least will be renewed each two years and the objections to further appropriations to one of Asheville's most worthy charities will doubtless be removed.

Quick and Good Work.—The handsome annual octavo volume of Transactions of the State Medical Society of North Carolina, edited by the secretary, Dr. John A. Ferrall, appeared the last week of August, within seventy days of the meeting, containing a full report of the June session of the state society at Morehead City, the various papers presented, obituaries of deceased members of the profession, proceedings of the State Board of Health, State Association of Public Health Officers and a number of tables containing valuable data relative to the society.

State Sanatorium Closed.—By order of the board of directors the State Sanatorium for Tuberculosis at Montrose was closed September 15. Dr. M. Eugene Street, superintendent, has also tendered his resignation, which has been accepted by the board. Additional improvements are being made and the directors hope to fill the vacant superintendency and reopen the institution by the middle of October. Following the closing of the sanatorium there was held a called session of the State Board of Health in Raleigh last week, where a proposition from the sanatorium board of trustees was considered by the Board of Health. By mutual consent a bill will be introduced in the present special session of the legislature providing that the members of the State Board of Health shall become *ex officio*, the board of directors of the State Sanatorium for Tuberculosis, and abolishing the present board of sanatorium directors. With the entire control of the State Tuberculosis Sanatorium in its hands, it is the purpose of the State Board of Health to inaugurate a statewide campaign of education for the management of tuberculosis, and especially to secure for as great a number of early stage patients as may be possible a brief stay in the state institution where opportunities for learning how to care for themselves may be afforded. The plans of the Board of Health meet with the cordial approval of present sanatorium directors, who will cooperate in the efforts to secure larger results from the state's investment at Montrose.

PENNSYLVANIA

New Hospital.—As a memorial to his wife, the late Stella M. Elkins, George W. Elkins is erecting at Abington a modern hospital. Announcement of the action of Mr. Elkins was made September 25. It had been planned to build the institution by the aid of public subscription. The cornerstone was laid by Mr. Elkins on September 26, and the hospital will be called the Abington Memorial Hospital, instead of the Abington General Hospital, the name selected by those who started the movement of its erection. The gift of Mr. Elkins has been accepted by the board of trustees, and is said to be about $100,000.

Meeting of State Medical Society.—The meeting of the Medical Society of the State of Pennsylvania was held in Philadelphia, September 22 to 25. Over one thousand registered. The visitors were entertained the day preceding the opening, and the day after the closing of the scientific meeting by clinics in all of the prominent hospitals of the city. Much interest was manifested in the resolution recommending the reporting to the health authorities of all forms of venereal disease. This resolution was adopted by the society. The next meeting of the society will be held in Pittsburgh. The following officers were elected: president, Dr. E. B. Heckel, Pittsburgh; vice-presidents, Drs. Henry D. Jump, Philadelphia, J. B. Anderson, Waynesboro, J. H. Wilson, Philadelphia and J. B. McMurray, Washington; secretary, Dr. C. L. Stevens, Athens (reelected); assistant secretary, Dr. William H. Cameron, Pittsburgh; treasurer, Dr. George W. Wagoner, Johnstown.

Philadelphia

Course in Eugenics for School Girls.—A special course in eugenics, in connection with the study of physiology, has been devised for the students in the high schools for girls of this city.

Report of Membership in State Society.—The report of the secretary of the state medical society, Dr. C. L. Stevens, at the sixty-third annual meeting of the society, shows that the membership numbers 6,044. This is a gain of 271 over the previous year.

Dr. Neff Asks for Typhoid Experts.—Dr. Neff, director of the Department of Health and Charities, has asked the Civil Service Commission to suspend competitive examinations in order that he may obtain the service of either Prof. William T. Sedgewick or Prof. George C. Whipple of Boston, in abating the epidemic of typhoid fever now prevailing in this city.

Medical Colleges Open.—During the past week all the medical colleges of this city, excepting the medical department of the University of Pennsylvania, were opened for the session of 1913 and 1914. In nearly all there was a falling off in the number of students admitted in comparison to previous years. In some, where the entrance requirements were originally forced, the freshman classes have fallen off 30 per cent.

Indeed, the reduction in the number of admissions may reach 50 per cent.

Personal.—Dr. Robert C. Parrish has been appointed supervisor of the Public School Medical Inspection Corps, to succeed Dr. Ralph H. Spangler.——Dr. Robert J. Hunter has been appointed by Dr. Neff to the Corps of Medical Inspectors.——Dr. Charles F. Nassau has been appointed professor of applied anatomy in Jefferson Medical College to succeed the late Dr. George McClellan.——Dr. Morris Jastrow has accepted an invitation from the Royal Society of Medicine of England to deliver the lecture of "The Hospital of Early Medicine." Professor Jastrow sailed for England September 27.——Dr. M. B. Hartzell has been made assistant diagnostician and consultant for the Bureau of Health, to succeed Dr. J. F. Schamberg.

GENERAL

Health Officer Goes to Refugee Camps.—Dr. E. S. McCain, who is in charge of quarantine work of the State Board of Health at Galveston, has proceeded to Tampico, Mexico, to assume charge of the refugee camps at that place.

Polish Physicians Hold Meeting.—The first annual convention of the Polish Physicians' Alliance of America was held in Detroit, September 19 and 20. Dr. Francis E. Fronczak, Buffalo, N. Y., was elected president; Dr. Stanislaus N. Borowiak, Buffalo, N. Y., secretary, and Dr. Edmund P. Koneczny, Detroit, Mich., treasurer.

Repeated Physical Examination of Engineers Urged.—Rigid annual government physical and mental examinations of every government engineer in the United States, and of others to whom are entrusted the safety of interstate travelers will be suggested to Congress by Surgeon-General Rupert Blue, U. S. P. H. S., and Congress will be asked to frame a statute placing this work under the department of commissioners and the officers of the Public Health Service.

Choose New Emblem.—The special committee of the National Association for the Study and Prevention of Tuberculosis, of which Dr. Henry Barton Jacobs is chairman, has announced the exact proportions of the double red cross, the international tuberculosis emblem adopted for use. The design chosen is one in which all the arms are pointed, the two cross arms being the same length. The width of the cross is taken as the unit, the length of the lower leg being 7 units, the arms 3 units on either side, the points above the arms 2½ units, and the distance between the arms 1½ units.

Meeting of Obstetricians and Gynecologists.—At the twenty-sixth annual meeting of the American Association of Obstetricians and Gynecologists, held in Providence, R. I., September 16 to 18, the following officers were elected: president, Dr. Charles N. Smith, Toledo, Ohio; vice-presidents, Dr. Hugo O. Pantzer, Indianapolis, Ind., and Dr. J. H. Branham, Baltimore, Md.; secretary, Dr. E. Gustav Zinke, Cincinnati, Ohio (reelected); executive council, Drs. Charles L. Bonifield, Cincinnati, Ohio, Herman E. Hayd, Buffalo, N. Y., John W. Keefe, Providence, R. I., X. O. Werder, Pittsburgh, Pa., Miles F. Porter, Fort Wayne, Ind., and Louis Frank, Louisville, Ky.

Prevention of Infant Mortality.—The fourth annual meeting of the American Association for the Study and Prevention of Infant Mortality will be held in Washington, D. C., November 14-17, with headquarters at the Willard Hotel. The subjects which will be discussed will include: eugenics, pre-natal care and instruction of mother, adequate obstetrical care, problems of infant hygiene and infant feeding, standards of training for infant welfare nursing, continuation schools of homemaking, the relation of vital statistics to plan for social betterment and the relation of the plans for the conservation of infant life to the general ideals of conservation.

The Missouri Valley Physicians' Meeting.—The twenty-sixth annual meeting of the Medical Society of the Missouri Valley was held in the Rome Hotel, Omaha, September 18 and 19. The address on surgery was delivered by Dr. Charles H. Mayo, Rochester, Minn., and the address on medicine by Dr. Alfred C. Croftan, Chicago. The following officers were elected: president, Dr. Flavel B. Tiffany, Kansas City, Mo.; vice-presidents, Drs. Granville N. Ryan, Des Moines, Iowa, and Austin McMichael, Rockport, Mo.; secretary, Dr. Charles Wood Fassett, St. Joseph, Mo. (reelected), and treasurer, Dr. Oliver C. Gebhart, St. Joseph, Mo. Lincoln, Neb., was selected as the place for the semi-annual meeting.

Railway Surgeons Elect.—The annual meeting of the Pennsylvania Railroad Surgeons' associations, and of the lines East and West, was held in Atlantic City, September 22 and 23. The associations voted to hold their meetings next year in the same place and the following officers were elected: Lines East.—President, Drs. George L. Romine, Lambertville, N. J.; vice-presidents, Herbert F. Gillette, Cuba, N. Y., and William Martin, Atlantic City; secretary, Dr. A. W. Colcord, Clairton, Pa.; treasurer, Dr. Joseph C. Egbert, Wayne, Pa. Lines West.—President, Dr. H. P. Linsz, Wheeling, W. Va.; vice-presidents, Drs. Hiram J. Coon, Colfax, Ind., and Charles Graefe, Sandusky, Ohio; secretary, Dr. J. D. McCann, Monticello, Ind.; treasurer, Dr. O. E. Holloway, Knightstown, Ind.

New Officers of Public Health Association.—At the annual meeting of the American Public Health Association, held in Colorado Springs, September 9 to 12, the following officers were elected: president, Dr. W. C. Woodward, Washington, D. C.; vice-presidents, Drs. John F. Anderson, U. S. P. H. S., Washington, D. C., Mario Labredo, Havana, Cuba, and C. J. Hastings, Toronto, Ont.; secretary, Prof. Selskar M. Gunn, Boston (reelected); treasurer, Dr. Livingston Farrand, New York City (reelected). Lee K. Fraenkel, New York City, was appointed chairman of a new committee to unite more closely the sociologic section of the association with that of vital statistics, and also to interest large corporations in the industrial health campaign now being urged. The Section of Public Health Officers elected Dr. C. V. Chapin, Providence, R. I., chairman, Dr. Nolan Pauchan, Ottawa, vice-chairman, and reelected Dr. E. C. Levy, Richmond, Va., secretary, and Dr. A. S. Fell, Trenton, N. J., recorder. Jacksonville, Fla., was selected as the next place of meeting.

Bequests and Donations.—The following bequests and donations have recently been announced:

Seney Hospital, Brooklyn, N. Y., $1,000 by the will of Mrs. Emmalissa Pervis.

Auburn (N. Y.) City Hospital, $20,000, Women's Hospital in the State of New York, $5,000, Presbyterian Hospital, New York City, $5,000 by the will of Homer N. Lockwood.

University of Pensylvania Hospital, $5,000, for the maintenance of a bed in the orthopedic ward in that institution, by the will of Fannie H. Dixon.

Invalids' Home and Maternity Hospital in Philadelphia, $5,000, by the will of Cornelius A. Lane.

Hahnemann Hospital, $5,000, by the will of Margaret H. Frederick.

St. Louis Medical Society, residue of the estate of $50,000 after payment of certain legacies, to set up and maintain a room in memory of her son, Hugo Barscher, by the will of Mrs. Franziska Barscher, St. Louis.

Sibley Hospital, Washington, D. C., $50,000, donated by George O. Robinson, Detroit, in the name of the Women's Home Missionary Society of the Methodist Church.

Newport (R. I.) Hospital, $4,000, donated by Mrs. William G. Weld, Boston, to establish a free bed in memory of her husband, and $1,000 donation from Stewart Duncan.

Infectious Diseases.—During September the chief interest concerning infectious diseases centered, perhaps, in the annual conference on pellagra in South Carolina. The apparent large increase and wider distribution of pellagra, both in this country and abroad, has made it of the highest importance among the infectious diseases. Prof. Louis Sambon, of the London School of Tropical Medicine, who attended the conference, reported that over fifty cases of pellagra had been discovered in Great Britain, where previously it was thought the disease did not exist. Cases have been reported more recently from The Shetland and Hebrides Islands. The comparatively recent discovery of several thousand cases of the disease in Mississippi is also an additional index of its great prevalence. The pellagra conference developed nothing particularly new as to the etiology of the disease. The infectious theory is probably gaining stronger hold through the intensive studies of the Thompson-McFadden Commission in South Carolina and others studying the disease, and the theory of the rôle of insects in its transmission is probably gaining strength. While Professor Sambon still adheres to the insect theory of transmission, he does not insist that the simulium, or sand-fly, is the only insect involved. Others of the conference were inclined to the belief that flies were the more probable conveyors.——But few cases of poliomyelitis have been reported throughout the country during the month. The season of 1913 has not recorded many cases of poliomyelitis. With the opening of the school season there has been a slight increase in the number of scarlet fever and diphtheria cases reported.——Under date of September 22, cholera is reported from Kherson, Odessa, and Sebastiaport, Russia, and from Bucharest, Roumania, from which place 1,137 cases with forty-five deaths have been reported.——Two fatal cases of plague have been reported from California, one in a laborer at Martinez during the present month, and the other in a Japanese woman, a field-worker, in San Benito County earlier in the summer. The diagnosis in both cases was confirmed by Dr. J. D. Long and Dr. D. H. Curry of the U. S. Public Health Service at San Francisco.

promotion in the Legion of Honor for the principal collaborators of this establishment. Owing to the renown of Pasteur's studies of rabies, an international subscription opened by the Académie des Sciences de Paris soon amounted to $500,000 (2,500,000 francs), and permitted the foundation, Nov. 18, 1888, of the Institut Pasteur. It was too small almost as soon as it was built, so numerous were the workers who congregated there from all parts of the world. Following a paper by Dr. Roux in the Budapest congress in 1894 on the treatment of diphtheria, a new subscription opened by the *Figaro* brought in about $200,000 (1,000,000 francs). It was used in arranging in the estate of Garches, lent by the government, great stables where it was possible to immunize a large number of horses to furnish antidiphtheria serum. The success of serotherapy drew to the Institut Pasteur new donations which were counted by millions and which permitted the acquisition in Paris itself, between the rue Dutot and the rue de Vaugirard of more than 14 hectares (about 34 acres) for the building of a hospital of 100 beds and of an institute of chemical biology facing the old laboratories of physiology and pathology. It is interesting to know that among the gifts the largest and most numerous were from Jews. The most important bequest in 1907 was from the banker and philanthropist, Osiris, which amounted to over $4,000,000 (20,000,000 francs). As M. Daniel Berthelot, professor in the Faculté des Sciences de Paris, recently observed, the gifts which have permitted the foundation and the development of the Institut Pasteur are comparable with those in which the New World takes pride. The character of the gifts, however, is different. In the United States such gifts are bestowed almost indifferently on pure science and humanitarian objects. Among us the enthusiasm which causes the gift of millions for a library or observatory is not so readily excited. At present the Institut Pasteur is a center at once of scientific research, of higher instruction and of therapeutic treatment. It is divided into three principal sections, a microbiologic section, a serotherapeutic section, and a section of biologic chemistry. One of the sources of superiority of the Institut Pasteur consists in its independence. It was founded and is carried on without official superintendence and hence has a spirit of initiative and of adaptiveness which administrative oversight scarcely permits to our government establishments.

The Mortality from Syphilis

At one of the recent sessions of the Société française de dermatologie et de syphiligraphie, Dr. Leredde read a paper intended to prove that in a great city like Paris, after tuberculosis, syphilis is the most frequent cause of death, exceeding cancer. In 1910, for example, 11,000 deaths, in round numbers, were due to tuberculosis and 2,500 to cancer. According to the researches of Leredde, at least 3,000 deaths are due to diseases caused by syphilis. Official statistics, however, attribute to syphilis only a small number of the deaths which are really caused by it. "The language of statistics," says Leredde, "like the language of medicine, is still an anatomoclinical language at many points; that is, it is incomplete. When statistics attribute a death to round ulcer, angina, softening of the brain, or spinal diseases, it may be due to syphilis that the physician has neglected to investigate or to mention. Reckoning up the deaths due to the diseases of the nervous system, circulatory system, etc., Leredde concludes that out of 10,821 deaths in 1910, syphilis was responsible for 3,374, or a little more than 31 per cent.; and even at that he has not reckoned non-tuberculous diseases of the larynx, diseases of the lungs, of the pancreas, of the spleen and of the thyroid; diabetes, which is sometimes of syphilitic origin; gastric ulcer, of which syphilis is perhaps often the cause; icterus gravis, and especially the diseases comprised under the headings "congenital debility, icterus and scleroma of the new-born," which caused 1,268 deaths in 1910.

Dr. A. Renault made several apparently well-grounded objections, remarking that one must not fall into the error humorously touched on by Ricord, who said that, according to the way things were going, internal pathology would soon become an annex to syphilis. While there is no question of the diagnostic value of the Wassermann reaction, it should be remembered that this reaction has not always the significance accorded to it with regard to visceral lesions. "Post hoc, ergo propter hoc" is not always correct, and the existence of syphilis does not justify the assertion of the syphilitic nature of a concurrent disease. The statistics of the tertiary stage show that in most cases syphilis is not the terrible disease that Leredde would make it. Out of 2,396 cases, Professor Fournier has observed only 3 per cent. of tertiary complications in patients who have taken treatment for at least three years. Professor Jadassohn of Berne, who is carrying on similar researches on prostitutes, has come to similar conclusions. He found only 4.6 per cent. of tertiary complications among those who had been regularly treated, and every one knows how poorly these women observe the laws of hygiene. Recent statistics of W. Perls are still more conclusive. From a study of the cases of syphilis treated at the Breslau clinic from 1901 to 1907 he found that out of 6,203 syphilitics only 1.0 per cent. had tertiary manifestations. In view of the enormous number of syphilitics in the world, it is not surprising that a positive Wassermann reaction is so often encountered, but the presence of a positive Wassermann does not justify the assertion that the visceral lesion from which the patient suffers is syphilitic. The deviation of complement indicates that the subject is tainted with syphilis and that is all. This taint by no means excludes the possibility of other diseases.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Sept. 12, 1913.

Personal

A few weeks ago Professor von Behring met with a serious accident. He slipped and sustained a fracture of the neck of the femur; this was complicated by a gastric fever so that he was seriously ill for some weeks. At the present time he is under treatment with an extension apparatus and consequently must keep his bed for a number of weeks longer. On this account, he is prevented from delivering an address on his new remedy at the Vienna Scientific Assembly.

The Rudolf Virchow Building of the Berlin Medical Society

As I stated some time ago, the projected building of the Rudolf-Virchow-Haus by the Berlin Medical Society has been markedly advanced by the aid of the Berlin municipal authorities. The committee in the city council has approved the suggestion of the city government on the matter, and it is to be expected that the council as a whole will pass the motion. The building is to have three assembly rooms for demonstrations, a Virchow museum and a library calculated to contain 200,000 volumes, together with a reading-room.

The Purchase of Mesothorium

The favorable results which have been obtained with mesothorium radiations in carcinoma by the gynecologist Bumm, Krönig and others have excited great attention in our newspapers and partly under the pressure of public opinion and partly instigated by the wishes of the directors of the hospitals, the municipal authorities in a number of cities, as I have already mentioned, have determined to purchase some mesothorium and radium. Berlin has appropriated $50,000 (200,000 marks) for this purpose, and $200,000 (800,000 marks) have been appropriated for the same purpose by the Prussian Department of Education. It is to be hoped that further success will justify this not inconsiderable material sacrifice.

Regulation of the Working Conditions of Nurses

Complaint has been repeatedly made in the newspapers and general congresses that the pay of nurses is insufficient and particularly that the hours of work are too long. These grievances are encountered not only in hospital service but also in private nursing. As these complaints must be regarded as justified from the viewpoint of physicians, our government has taken the matter up and a collective inquiry with regard to the special conditions in the German Empire has been instituted by the Imperial Department of the Interior. At the same time, measures are being tried which have for their purpose the regulation of the working conditions of nurses. As soon as the investigations are concluded, a general regulation with reference to the beginning and ending of the day and night service will be adopted by the Bundesrat.

Comparative Health Statistics of the Berlin and Paris Garrisons

The superiority of the hygienic conditions of the German Army to those of the French appears again in a report which has recently been published in a French professional journal by a French investigator. Especially, there is an instructive comparison between the health of the Berlin and Paris garrisons. During a recent five-year interval there were 17,503 cases of illness in the Berlin garrison with an average strength of about 66,000 men. On the other hand, in the Paris garrison with a strength of about 45,000 men there were 37,000 cases of illness. In Berlin there were 182 deaths or 0.54 per cent.; in Paris, 516 or 2.3 per cent. A large part of the morbidity in the Paris garrison was due to measles and tuberculosis. The inferior condition of the Parisian garrison is to be attributed to insufficient hygienic measures, of which not the least is the circumstance that the barracks occupied by the garrison are nearly all antiquated buildings.

Housing of Berlin Salespersons

As is the annual custom, the local Krankenkasse of merchants' clerks has again published an extensive report of the housing conditions of the sick policy-holders. In spite of various improvements, the same unfavorable conditions in general were found as in previous years. The dwellings of 13,903 members of the society who were unable to work were investigated during the year. Of these patients, 7,052 live in front houses, 6,851 in rear houses. Of 803 patients who live in rooms having up to 10 square meters of floor space (about 100 square feet), 225 share this space with another person, 106 with two persons, 23 with three, 2 with four and 1 with seven. Over 3,730 patients live in rooms the height of which was not up to the minimum of 2.8 meters (about 9 feet). In 4,777 dwelling-rooms, the air space was not 20 cubic meters per person (about 20 cubic yards). There were 1,524 rooms which had less than 10 cubic meters of air space; this is less than the minimum requirements of the first Prussian housing law. The inspectors found 174 persons who have only 5 cubic meters of air space at their disposal. Moreover, 65 rooms had no windows and 671 patients shared their living-room with five other persons, 348 with six and 297 with more persons.

Among the lodgers, about 14 per cent. were pulmonary invalids and about 7 per cent. suffered from acute infectious disease, which indicates the marked danger of infection from night lodgers. Fully 1,717 patients lived in one-room dwellings (kitchen or sitting-room). Altogether 213 men and 236 women were found who had to share their sleeping-rooms with five and more persons, although they were ill. Of the patients living in families, 344 and of those living in sleeping rooms or furnished rooms, 87 occupied rooms with no provision for heat. In regard to sanitary conditions, 634 had to use a water-closet in common with 16 and more persons. A third of those in the front tenements and more than half of those in the rear tenements had to leave the apartment if they wished to use the closet.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, Sept. 10, 1913.

Cholera in Austria

In the frontier provinces of the empire sporadic cases of cholera were reported during the first half of this year, but since the war is over and the soldiers are dismissed the disease has been spread over the countries engaged in war and also has been transmitted to us. In Hungary 167 cases have been reported up to the present, while in Austria only forty-nine cases have been discovered. But there is no doubt that we are only at the onset of the attack, and that preventive measures will have to be most stringently used to check its progress. Even in Vienna two cases were found though they have so far remained the only ones.

Medical Subjects in the Meeting of Statisticians

The month of September is really the month of congresses and meetings of societies for Vienna. No less than four take place here this year: the statistical, the pharmaceutical, the congress on first aid, and the congress of German practitioners and scientists. Only the first need be mentioned here. There were some points brought out through papers read in this congress which every medical man should keep in mind. Thus one report dealt with the fertility of marriages in Belgium and France. In all European countries the number of births has gone down rapidly within the last twenty years. This holds good not only of legitimate but also of illegitimate children. Interesting data were brought forth to show that within the first six years of matrimony more wives die than husbands, while after this period more husbands die than wives. No doubt the risks of the first childbirths are responsible for this fact. The average duration of matrimony is twenty-nine and one-third years. Another paper (by Tschuprow of Russia) dealt with the diminishing surplus of boys in the number of legitimate births. In the European countries, all show this tendency. Tschuprow believes that the increase of miscarriages, which is well marked within the last two decades, is responsible for it, for the male embryo is more prone to miscarriage than the female. The statistics for Germany show the same conditions. It was decided to ask the sick clubs and other friendly societies to pay more attention to these occurrences in their statistical reports.

A Pharmaceutical Exhibition

An interesting exhibition is now on view in Vienna which comprises all objects pertaining to pharmacy and apothecaries Apart from the purely scientific exhibits, those dealing with the history of medicine are most instructive. Two collections illustrative of ancient and medieval chemistry and pharmacy were exhibited which show distinctly the progress made in this line within the last half century. Apart from the more than doubtful composition and origin of the majority of the remedies used in those times, the use of drugs half a century ago was attended with a low degree of scientific certainty. A distinct feature of the exhibition is the prominence which is given to the "spas" and health resorts. Hydrotherapeutic and balneotherapeutic measures are indispensable in modern times, and they can thus be easily studied in a variety of applications and activities. A large space is allotted to the radioactive substances which have lately come into so marked a prominence. It is interesting to note, as hitherto, that Austria is still the chief producer of radium (mostly from the pitchblende of Joachimsthal) while the chief buyers are in the United States. A most instructive addition to the exhibits are tables which show the money value of the trades involved in the pharmaceutical business as well as the cost of certain drugs in retail and wholesale quantities. Especially in Austria and Germany, where prescriptions may be made out by apothecaries only, the price of simple mixtures or powders is often in comparison with their cost ridiculously high. This is due to the intricacies of the official price-list which is made out every few years by the government. The friendly societies and sick clubs have appointed a special officer whose duty it is to control the methods of prescription used by the club doctors, and a synopsis of economical prescriptions is issued to the medical officers of the Krankenkassen.

Marriages

WILLIAM D. HAMMOND, M.D., Hagerstown, Md., to Miss Camille Bringhurst of University City, St. Louis, at Alton, Ill., September 16.

LAWRENCE JACOBS QUILLIN, M.D., Streator, Ill., to Miss Ethel Shrimplin of Mount Ayr, Ia., at Warsaw, Ind., September 15.

MARVIN MCRAE SCARBROUGH, M.D., New Haven, Conn., to Miss Mabel Gertrude Sherwood of Bridgeport, Conn., September 6.

GEORGE BALL ROWELL, M.D., San Bernardino, Cal., to Mrs. Louise Schwarz of Los Angeles, at Riverside, Cal., September 13.

PETER PRENTISS CAUSEY, M.D., Wilmington, N. C., to Miss Esther Elizabeth Brewington of Baltimore, September 17.

WALTER A. DEW, M.D., Belleville, Ill., to Miss Mary Wise of Granite City, Ill., at Edwardsville, Ill., September 18.

SAMUEL KENNEDY CHRISTY, M.D., Willshire, O., to Mrs. Elpha Miller of Pleasant Mills, Ind., September 10.

HEILMAN CURTIS WADSWORTH, M.D., Washington, Ind., to Miss Elizabeth M. Beale of Chicago, September 11.

FRANKLIN W. CREGOR, M.D., Indianapolis, Ind., to Miss Gertrude Horn of Valparaiso, Ind., September 24.

EUGENE JULIUS HAMBORSZKY, M.D., Farrell, Pa., to Miss Clara McEllafflin of Lancaster, Pa., September 16.

WILLIAM DAVIS PHILLIPS, M.D., New Orleans, La., to Miss Mary G. Scott of Lexington, Mass., September 9.

JAN JAROSLAV CEPELKA, M.D., to Miss Frances Pacak, both of Chicago, at Crown Point, Ind., September 18.

ALLEN HENRY DUNTON, M.D., Cincinnati, O., to Miss Ava A. Ripley of Minneapolis, Minn., August 28.

GEORGE IVES, M.D., St. Louis, to Miss Loretta Trentle of West Virginia, at St. Louis, August 18.

AHAB HAINES LIPPINCOTT, M.D., to Miss Miriam Lee Early, both of Camden, N. J., September 8.

Charles M. Rickert, M.D., to Miss Sarah Enterline, both of Millersburg, Pa., September 10.

Edward Lyman Cornell, M.D., to Miss Mabelle Jane Cass, both of Chicago, September 16.

John A. Brophy, M.D., to Miss Caroline M. School, both of Philadelphia, September 17.

Deaths

Ephraim Wood Norwood, M.D. Harvard Medical School, 1882; a fellow of the American Medical Association; councilor of the Massachusetts Medical Society; president of the Worcester District Medical Society, and medical examiner of the Ninth District of Worcester County; for many years a member of the school board of Spencer, Mass., and president of the board of trustees of the Hitchcock Free Academy, Brimfield, of which he was principal from 1869 to 1879; died at his home in Spencer, September 11, from heart disease, aged 67.

Robert S. Wallace, M.D. Jefferson Medical College, 1855; a fellow of the American Medical Association; the oldest surgeon in the employ of the Pennsylvania System; also surgeon at East Brady for the Allegheny Valley Railroad; who was given a complimentary banquet by the medical fraternity of three counties in 1907, at which he was presented with a loving cup and was declared to be "the most eminent country doctor in the state;" died at his home in East Brady, September 14, aged 81.

Hugh Sumner Wyman, M.D. Michigan College of Medicine, Detroit, 1882; formerly a member of the American Medical Association; a member of the Washington State Medical Association; for more than a quarter of a century a pracitioner of Alaska and Washington and for several years in harge of the United States Marine Hospital at the Treadwell mines, Alaska; died at his home in Olympia, Wash., September 12, aged 54.

Letcher W. Smith, M.D. College of Physicians and Surgeons, Dallas, Texas, 1906; a member of the State Medical Assoiation of Texas; formerly a practitioner and a member of he board of education and local surgeon for the Texas and New Orleans Railroad at Sacul; was found dead in his room in a hotel in Houston, Texas, September 10, from acute dilaation of the heart following typhoid fever, aged 31.

James Frederick Berlet, M.D. Jefferson Medical College, 877; formerly a member of the American Medical Associaion; resident physician at the German Hospital and visiting hysician to the Foster Home, Philadelphia; at one time a urgeon in the Army; died at his home in Philadelphia, Sepember 14, after an operation for gangrenous diverticulitis, aged 62.

Garland Payne Moore, M.D. College of Physicians and Surgeons, Baltimore, 1886; acting assistant surgeon U. S. P. H. S.; a member of the Medical Society of Virginia; whose last station was at Kobe, Japan, where he was on duty at the American Consulate; died suddenly at sea September 9, while en route to the United States, aged 49.

Henry Franklin Broyles, M.D. Tulane University, New Orleans, 1889; of Greenwood Springs, Miss.; for twenty years a member of the House of Representatives from Monroe County and at the time of his death state senator; was shot and killed in an encounter in which he killed his assailant with an ax, September 16, aged 48.

William Maurice Moore, M.D. University of Missouri, Columbia, 1880; Bellevue Hospital Medical College, 1881; a member of the State Medical Association of Texas; of Paris, Texas; a specialist on diseases of the eye, ear, nose and throat; died at a hospital in Paris, September 9, after a surgical operation, aged 54.

Adolph Hochstein, M.D. Graduate of the Friedrich Wilhelm University, Berlin, in 1870 (license, Michigan, 1900); a fellow of the American Medical Association and for thirty-seven years a practitioner of Kalamazoo; died at his home in that city, September 12, from disease of the stomach, aged 68.

M. Wendell Case, M.D., University of Louisville, Ky., 1851; of Philadelphia; who became a musician after a few years of medical practice and was at one time president of the National Conservatory of Music; died at his home in Philadelphia, September 10, from arteriosclerosis, aged 83.

Calvin Huntley Fitch, M.D. Cincinnati College of Medicine and Surgery, 1878; for several years physician for the Chesapeake and Ohio Railway during the construction period in Virginia; died at the home of his son-in-law in Augusta, Me., August 21, from cerebral hemorrhage, aged 84.

S. T. Davidson, M.D. University of Pennsylvania, Philadelphia, 1854; a Confederate veteran and practitioner of Charlotte Road, Nashville, Tenn., for more than half a century; died in St. Thomas' Hospital, Nashville, August 29, from senile debility, aged 81.

John Archibald McDonell, M.D. University of Buffalo, New York, 1875; a member of the Illinois State Medical Society; professor of surgery in Bennett College of Eclectic Medicine and Surgery, Chicago; died at his home in that city, September 19, aged 66.

Jacob Lorenzo Smith, M.D. Western Reserve University, Cleveland, 1873; a member of the Mississippi State Medical Society and for many years a practitioner of Durand, Miss.; died at the Pontiac State Hospital, September 13, aged 70.

Samuel C. Dunkle, M.D. Kentucky School of Medicine, Louisville, 1881; a member of the Ohio State Medical Association and a resident of Glidden; died in Rochester, Minn., September 11, three weeks after a surgical operation, aged 66.

John D. Armfield (license, Indiana, 1897); a practitioner of Indiana since 1865; one of the organizers of the Elwood State Bank and a member of the board of education; died at his home, September 10, from senile debility, aged 74.

George S. Guernsey, M.D. Vermont Medical College, Woodstock, 1851; a pioneer practitioner of Keosauqua, Iowa, but for five years a resident of Los Angeles; died at the home of his daughter in that city, August 13, aged 91.

Zophar Case, M.D. Washington University, St. Louis, 1875; a fellow of the American Medical Association; for forty years a practitioner of Johnson County, Mo.; died at his home in Warrensburg, September 14, aged 66.

William Worth Bailey, M.D. University of Michigan, Ann Arbor, 1861; a pioneer practitioner of Arkansas; surgeon of volunteers during the Civil War; died at his home in Fort Smith, September 15, aged 72.

John Brainard Carman, M.D. McGill University, Montreal, 1879; a fellow of the American Medical Association; died at his home in Detroit, Minn., about September 13, from staphylococcic bacteriemia, aged 58.

Evan F. Cowger, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1880; a veteran of the Civil War and for forty years a practitioner of Riverton, Iowa; died at his home, September 4, aged 70.

Hugh Lee Courtright, M.D. St. Louis College of Physicians and Surgeons, 1909; formerly of Kellerville, Ill.; died at the home of his mother in Des Moines, Iowa, September 15, from tuberculosis, aged 28.

Alfred S. Bellamy, M.D. Hahnemann Medical College, Chicago, 1876; founder and president of the Florence (Ala.) Wagon Works; died at his home in that city, August 5, from cerebral hemorrhage.

John Sherer Bardwell (license, Pennsylvania, 1881, as graduate of the American Health College, Cincinnati); for fifty-six years a practitioner of Ridgway; died at his home, September 8, aged 79.

George R. Bartran, M.D. Chicago Medical College, 1872; for thirty-four years a resident of Algoma, Wis.; died at his old home in Smithboro, N. Y., August 27, aged 72.

Amandus N. Fegley, M.D. Jefferson Medical College, 1870; died at his home in Oley, Pa., September 4, from gangrene following an infected wound of the foot, aged 70.

James Edward Cage, M.D. University of Nashville, Tenn., 1868; a Confederate veteran; died at his home in Carmel, Tenn., September 14, from uremia, aged 76.

Nathan Herman, M.D. Louisville (Ky.) Medical College, 1894; died at his home in that city, September 13, from acute gastritis, aged 50.

Thomas B. Lloyd, M.D. Missouri Medical College, St. Louis, 1868; died at his home in Paris, Mo., August 6, from senile debility, aged 73.

Samuel Henderson, M.D. Jefferson Medical College, 1873; died at his home at Franklin, Tenn., August 15, from angina pectoris, aged 62.

Charles H. Eckert, M.D. Fort Wayne (Ind.) College of Medicine, 1889; died in his apartments in Marion, Ind., August 21, aged about 55.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

SWINDLING WOMEN

Some Female Weakness Cures and Allied Frauds

A series of scholarly articles on quackery and the nostrum evil appeared in *Vanity Fair* two or three years ago by Mr. Henry Sewill. The author devoted one article to "Quackery for Women" whose opening paragraph ran thus: "Among the victims to quackery of every sort women far outnumber men. They are always more trustful, and, as a rule, find it more difficult, especially when suffering, to believe that anyone can be base enough to abuse their confidence, much less to take advantage of their helplessness in order to plunder and injure them."

The paragraphs which follow were written to complete a pamphlet entitled "Viavi, 'Female-Weakness' Cures and Allied Frauds"[1] which has been prepared especially for the enlightenment of women on the subjects with which it deals. The matter is reproduced here because of many inquiries THE JOURNAL receives from physicians regarding concerns of this sort indicates a demand for information.

Mrs. Ida M. Ade

The Kokomo Medicine Company, of Kokomo, Ind., advertises a "free home treatment for female trouble" under the name of Mrs. Ida M. Ade. Those who write to Mrs. Ade for the treatment get a form letter printed in imitation handwriting. Mrs. Ade recommends the recipient of her letter to order a 30-day "Vitopian Home Treatment," put up by the Kokomo Medicine Company. By the same mail, a stock letter and a small box containing a few pills and two vaginal suppositories comes from the Kokomo Medicine Company. The letter gives the price of the 30-day treatment as $3.50, but states that, on Mrs. Ade's urging, they "have decided to allow you the regular wholesale discount," which will bring the price down to $3. The whole scheme is a typical mail-order medical fraud.

Alpen Seal

Mrs. Georgia Palmer, of Chicago, advertises that she will send a "free prescription" for the relief of women's ailments. Those who write receive a letter printed in imitation handwriting. The "prescription" is printed in imitation typewriting on a prescription blank of George E. Flood, M.D., 79 Dearborn Street, Chicago. The "prescription" contains three items: Water, Fluid Extract of Black Haw and "Alpen Seal." The joker, of course, lies in the "Alpen Seal," which is a "patent medicine" put on the market by a concern calling itself the Alpen Chemical Company. Dr. George E. Flood of 79 Dearborn Street may also be found in nostrum literature as the writer of a testimonial for a fake bust developer put out by the Aurum Medicine Company, also of 79 Dearborn Street. "Alpen Seal" is also advertised by the "prescription fake" method in those newspapers that are not above sharing the profits of frauds of this type.

Atlanta Remedy Company

The Atlanta Remedy Company of Atlanta, Ga., is another branch of the W. M. Griffin fakery with headquarters at Fort Wayne, Ind. (See the article on Bertha C. Day.[2] Dr. Lily M. Norrell is the stool-pigeon in this case. The methods employed are practically identical with those used in the Bertha C. Day concern: the regular system of follow-up letters, "free proof treatment," testimonials and a 144-page booklet, entitled "Health at Home for Women." This booklet is said to be "published by the Atlanta Remedy Company, Atlanta, Ga." Except for the first eight pages, which describe Dr. Lily M. Norrell, "Medical Director, Atlanta Remedy Co.," the book is printed from the same plates as, and is identical with, the one issued by the "Woman's Remedy Company," San Francisco, another of Griffin's fraudulent mail-order medical concerns. As in the case of the Bertha C. Day concern, those who write to the Atlanta Remedy Company for the free trial treatment also have saddled on them a so-called "special treatment," which is sent at the same time as the trial treatment. For the latter, the victim is asked to pay $2 or $2.50. The value of this treatment may be gathered from the fact that if the victim refuses to accept it, the company does not consider it worth while sending the three cents postage necessary for its return. The business is essentially as fraudulent as that of its prototype, the Bertha C. Day Company.

Mrs. F. Beard Company

The Mrs. F. Beard Company, of Dayton, O., advertises in the classified columns of the newspapers, thus:

> "Ladies—Send 25 cents; catalogue Secrets for Women and box Dr. Baird's remedy. Safe, speedy, regular."

Those who send 25 cents receive a batch of advertising of the remedies of the F. Beard Company, and a small wooden box containing some black pills. The label on the box refers the recipient to a red circular sent in the letter. This circular urges the woman to "send immediately for Superb Pills No. 3," if the sample in the wooden box "does not bring about the monthly flow." According to the leaflet, "Superb Pills No. 3 are a new departure, being made triple strength." They are "made expressly for long-standing and aggravated cases." If taken each month "ladies will find themselves always regular," thus "saving them from worry" and pain. And the reader is told that "these pills should be used every month as a preventive of irregularities." Five dollars a box is asked for this unmitigated fraud. In addition to the nostrums, the company also sells various "rubber goods."

Dr. Charlotte Christopher

Dr. Charlotte Christopher operates—or did operate—a mail-order medical concern at 7 E. Randolph Street, Chicago. "This famous lady specialist" has "time after time taken cases pronounced hopelessly incurable by the medical profession and restored the patients to health in a most phenomenal manner"—she says so, herself. Dr. Christopher also said, in an advertisement published in a Chicago paper in 1910, that "after years of successful practice," she "decided to devote her future time to the relief of suffering women." Dr. Charlotte Christopher graduated from a low-grade Chicago medical college in 1907, so that the "years of successful practice" dwindle down to a paltry three—and these, evidently, were not "successful" or she would not be in the fraudulent mail-order medical business. Dr. Christopher, like most mail-order medical fakers, offers to send a free treatment to those answering her advertisement. Those who send for it receive a small box containing three different kinds of tablets: "Tonic," "Newlife," and "Healthtone." They also receive a request to send five dollars for the "full two months' treatment." The usual follow-up letters come to those who do not bite; she has a sliding scale of prices common to charlatans of this sort. Later follow-up letters indicate that Dr. Charlotte Christopher's business was succeeded to by the Newlife and Healthtone Co., Chicago, which, in turn, is said to be owned by the Panter Remedy Co, which operates a mail-order cure for syphilis ("blood poison").

Hager Medical Company

The Hager Medical Company, South Bend, Ind., is said to be owned by George L. Hager, who is president of the company, with A. M. Hager, treasurer, and J. L. Midgley, secretary. "Oak Balm" seems to be the most extensively exploited of the Hager concern's frauds, although it also puts out other products including "Fibroma Unguent," which the company advertises, by inference, as a cancer cure.

---

[1] This pamphlet sells for 6 cents.

[2] The exposé of the Dr. Bertha C. Day Company appeared first in THE JOURNAL, April 1, 1911; it has been reprinted in pamphlet form (price 4 cents) and also appears in full with later notes, in "Nostrums and Quackery."

Margaret M. Livingston

Margaret M. Livingston, M.D., of Chicago, advertises in the "personal" columns of newspapers as a "specialist for diseases of women." Those who write for the "free booklet" which she offers to send, receive, in addition to the pamphlet lauding Dr. Livingston and her methods, some printed slips describing various nostrums she has for sale. Two or three years ago Dr. Livingston seems to have been connected with a concern called the Central Health Institute which sold "For-Me-Ka Oil, Vitality Tonic Remedies." The incorporators of the Central Health Institute were, in addition to Dr. Livingston, Edith B. Lowry, O. A. Livingston and R. J. Lambert. The Chicago papers of November 21, 1912, reported the arrest of a number of persons throughout the country on the charge of misuse of the mails to solicit criminal medical practice or to dispose of medicines and instruments connected with such practice. Dr. Margaret Livingston's name was one of the twelve listed of those arrested in Chicago.

Orange Blossom Suppositories

Orange Blossom Suppositories are put on the market by J. A. McGill, M.D., Chicago. Since the Food and Drugs Act went into effect, the "Orange Blossom" part of the advertising has been less pronounced; also, many of the most evident falsehoods have been toned down, although there are still plenty. A product answering to this description was subjected to analysis by the chemists of the British Medical Association. They reported that "Orange Blossom Specific for Uterine Diseases," claimed to be "the invention of a Chicago doctor," had for its principal constituents alum and boric acid, the base being principally soft paraffin. Orange Blossom Suppositories are said to be "a noble remedy" for "cancers in their earlier stages." Incidentally, McGill puts out a "Famous Cancer Salve" and also a "kidney and bladder cure" which "never fails to cure any form of Bright's disease, diabetes," and various other conditions. Each is a fraud.

Phen-ix Chemical Company

The Phen-ix Chemical Company of Warsaw, Ind., sells "Anti-seps—a modern female remedy," "Stargrass Compound—Nature's tonic for women," "Phen-is-ine Nerve Vitalizers" and "Earl's Kidney and Bladder Pills." The concern advertises in the classified columns of newspapers and by means of display advertisements. The claims are fraudulent.

Harriet M. Richards

Mrs. Harriet M. Richards is the name under which the Woman's Mutual Benefit Company of Joliet, Ill., reaches its dupes. The advertisements of this concern are familiar to those who glance through the pages of some of the cheaper weekly magazines. "Mrs. Richards" offers to send her "sister woman" a "fifty-cent box of Balm of Figs Compound" which "will not cost her one cent." The woman who writes for the "free treatment" receives a small cardboard box containing two vaginal suppositories and a stock letter urging her to use them. With the letter is the usual "scare" booklet describing the dire effects of the various sexual ailments to which women are subject and telling of the wonderful cures that "Balm of Figs" has effected in all diseases of this sort. A day or two after receiving the "free trial treatment," another stock letter comes and with it a "regular-size" box of Balm of Figs suppositories, for which two dollars is asked. This box costs two cents to mail and, so far as we know, the company never sends those who refuse to accept it the two cents necessary for its return. The value of the contents is evident.

A cursory examination of Balm of Figs was made in the Association's laboratory and the results indicated that the nostrum is a mixture of borax, alum and linseed oil made into a paste. If the recipient does not send the two dollars, she receives at intervals "follow-up" letters of the usual type. As an additional inducement she is told that if the two dollars is sent "one of our splendid fountain syringes" will be sent free. The concern also handles other "patent medicines" and, as a side-line, "sanitary belts," and "skirt supporters." While the Harriet Richards concern professes to keep "all correspondence of whatever nature" confidential and private, as a matter of fact thousands of letters that have been written to the concern are on sale at letter brokers. The thing is an unmitigated fraud.

Sanova Company

Sanova is said to be a "famous specific" for "female weakness" and is put up in the form of vaginal suppositories. Under the caption "Why Men Desert Their Wives," the Sanova Company, Toledo, O., urges women to use their nostrum and thus "command the happiness and pleasures which all women are intended to enjoy." The concern sends out booklets of the "scare" type; it also sells other "patent medicines" as well as a "Ladies' Syringe." Works the "free-trial treatment" dodge.

Dr. Southington Remedy Company

The Dr. Southington Remedy Company of Kansas City, Mo., publishes in such newspapers as will accept them advertisements to this effect:

> "Ladies—$1,000 reward. I positively guarantee my great successful 'monthly' remedy. Safely relieves some of the longest, most obstinate abnormal cases in three to five days."

Those who write for information regarding this advertised abortifacient are sent a stock letter and a booklet telling of the wonderful results of taking "Dr. Southington's Ergo-Kolo Female Compound for Women Only." The price of this "regulating compound" is $1.50 a package "single strength," but the "double strength," which is recommended "for more obstinate cases," costs two dollars. The thing is an indecent fraud.

Mrs. M. Summers

Almost every one who has looked over cheap magazines and not-too-particular newspapers has seen the "Free to You—My Sister" advertisements put out under the name of Mrs M. Summers, South Bend, Ind. Mrs. M. Summers is the name under which Vanderhoof & Company exploit a fraudulent mail-order "female-weakness cure." Like Mrs. Harriet M. Richards, Mrs. Summers offers to send a "free trial" of her "home treatment." Those who write for the "free treatment" receive some "Opaline Suppositories" for vaginal use. Since the Food and Drugs Act ("pure food law") has been in effect, the Vanderhoof concern has had to declare the presence of opium in its suppositories, each suppository containing 1⅔ grains of this drug. With the suppositories, "Mrs. Summers" sends a sample of her "Compound Antiseptic Powder for Ladies." This antiseptic powder is for the "cure," among other things, of "suppressed menstruation." From the testimonials regarding this powder we take the following, alleged to have been sent in by a married woman:

FREE TO YOU—MY SISTER
Mrs M. Summers, Box H, Notre Dame, Ind., U. S. A.

> "I had not been unwell for four months before commencing your treatment, and after using it two weeks, I came around all right and have been regular ever since. . ."

Also, Vanderhoof & Co. sell "Vigor of Life." This is said to be a marvelous cure for women who have lost the "personal magnetism" and other "attractive attributes" that go with a "thoroughly developed and strong nervous organism." It is also good, we are told, "for women whose nervous organism peculiar to the sex has never fully developed." "Vigor of Life supplies that which is" necessary to "make the marital relations harmonious and complete." Furthermore, this wonderful product "prevents the insidious approach of failing manhood"—all this for one dollar a box. These and many other fakes emanate from the Vanderhoof fraud factory.

Incidentally, "Mrs. Summers' Harmless Headache Powder" has been declared misbranded under the Federal Food and Drugs Act ("pure food law"). Instead of being harmless, the United States authorities declared that it was "in truth and in fact injurious to health." A plea of guilty was entered and a fine imposed.

The Woman's Remedy Company

Dr. Grace Feder Thompson, "Specialist to Women, Medical Director," is the stool-pigeon in charge of the Woman's Remedy Company, San Francisco. This is another of the W. M. Griffin frauds, similar in scope to that of his older fraud, Bertha C. Day. The method of operation seems to be identical with that of the Atlanta Remedy Company and the booklet it sends out is, with the exception of the first few pages, printed from the same plates. The booklet in this case is entitled "Woman's Home Health Book," said to be "published by the Woman's Remedy Company, San Francisco, California." The Woman's Remedy Company sends to those who write for the "free-trial treatment" a "full and complete course," for which three dollars is asked. Those who do not swallow this bait receive a series of follow-up letters, each one more insistent than its predecessor, urging that the money be sent. If these, too, are unanswered, the concern comes down in price, but does not send the three cents necessary for the return of the three-dollar treatment.

Vis-Vitæ Medicine Company

The Vis-Vitae Medicine Company of Toledo, Ohio, sends a "free trial treatment" consisting of tablets for vaginal use. Uses the follow-up system in keeping after its victim. It is a somewhat paltry and insignificant swindle.

THE NEW ORLEANS "ITEM"

This Paper Makes New Rules for the Acceptance of Medical Advertising

The New Orleans *Item* put into effect October 1 a new set of rules governing the acceptance of advertising, with particular reference to medical "copy." The matter is commented on editorially in this issue. Here are the rules:

The New Orleans *Item* declines to accept advertising on any of the following class of articles or services:

1. Books, pictures, "rubber goods," or other devices or services, where the name of the device or the wording of the copy conveys, either directly or inferentially, that the article or service is of obscene, illegitimate, or questionable nature.
2. Medicines or methods for the cure or relief of diseases peculiar to women. This rule bars any copy containing such words or expressions as "women's diseases," "women's complaints," "ladies' friend," "tansy," "pennyroyal," "regulator," "preventive," and the like, and in general any verbiage that may be considered by the *Item* to be similarly offensive.
3. Medicines, methods, or devices for the cure or relief of diseases peculiar to men. This rule bars any copy whatever containing any such words or suggesting any such ideas as "lost manhood," "sexual weakness," "exhaustion," "impotence," "nocturnal emissions," "unnatural discharges," "gonorrhea," "impure blood," "syphilis," "gleet," "varicocele," and the like, or any copy that suggests them.
4. Medicines or mechanical devices that purport to "enlarge the bust," to "improve the figure," to make the fat thinner or the thin fatter, to restore hair to bald heads, change ugly complexions into beautiful ones, and, in general, to perform any other feats that are impossible or may be dangerous. It is not intended to bar toilet preparations of harmless composition, or legitimate massage devices that are truthfully advertised.
5. Any medicine that claims to cure or relieve diseases commonly held by medical science to be incurable in this way, such as tuberculosis, cancer and the like. This rule bars reference to such diseases by expressions designed to suggest them, such for instance, as "lung trouble" for consumption. This rule also bars indirect claims of cure or relief of such conditions, through testimonials or otherwise.
6. Any medicine that claims to cure or relieve any disease or injury whatever. This refers to *diseases*, not to *conditions*, such as constipation and the like, and does not bar harmless cathartics and other such remedies, when truthfully advertised.
7. Any medical treatment offered free.
8. Any advertisement not falling itself within the prohibition of these rules but leading to correspondence between advertiser and reader in which the principle of these rules is violated.
9. Any medicine containing a habit-forming drug of the dangerous class — opium or its alkaloids, cocain, heroin, chloral and the like. This rule bars preparations in which alcohol is present in quantities larger than pharmaceutical compounding requires and thus becomes one of the active agents, or the sole active agent, in the mixture. This clause, however, will not apply to "bitters" commonly known for their alcoholic content.
10. Medicine containing useful drugs or chemicals harmless in many cases, but potentially dangerous when indiscriminately administered — acetanilid and the like. Debatable cases of this sort will be settled in the discretion of the *Item*.
11. Any sort of text or illustration offensive to good taste, either in character or in appearance. This applies to all the class of grotesque, bizarre, or horrible pictures and expressions calculated to shock the reader into attention.
12. Copy that simulates in type, arrangement or otherwise, the *Item's* own reading matter.
13. Financial or commercial schemes or enterprises that the *Item* has reason to believe are fraudulent, or unsound, or exaggerated.

Correspondence

Serodiagnosis of Pregnancy

To the Editor:—The main difficulty so far in the serodiagnosis of pregnancy has been the danger of bacterial contamination. I have had no trouble since using the following precautions: 1. The prepared placenta is kept in distilled water containing a few drops of chloroform and a layer of toluol. Just before use a small piece of placenta is removed and boiled in a small quantity of distilled water. This insures sterility and also removes any chloroform present.

2. When ready the dialyzers are lowered into ordinary hydrometer jars without lips. After toluol has been added to the dialyze and the water, the jar is tightly corked. There is almost no evaporation.

3. Immediately after use the thimbles are thoroughly washed in running tap-water and drained by inverting them on a sheet of filter-paper. Just before use they are again washed and boiled in distilled water for three minutes.

S. L. Cherry, M.D., Clarksburg, W. Va.

[Comment.—The importance of such careful, aseptic technic has been emphasized repeatedly by Abderhalden and his pupils. We have commented on this subject previously. (The Present Status of Abderhalden's Serodiagnosis, editorial, The Journal, Aug. 16, 1913.)—Ed.]

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

CARUNCULAE MYRTIFORMES

To the Editor:—In The Journal, Aug. 30, 1913, p. 704, answering "Subscriber," you say: "The carunculae myrtiformes are the results of labor and not of the rupture of the hymen." Who told you so? Gray, Cunningham, Dorland's dictionary, McClellan's "Regional Anatomy" all say that the remains of the ruptured hymen are called "carunculae myrtiformes." Gerrish and Morris say practically the same, and none of them say that the carunculae are the result of labor.

C. W. Courtright, Chicago, Ill.

Answer.—"The hymen is usually torn at the first coitus, sometimes by gynecologic examinations or by masturbation. It is partially destroyed in labor, the remnants persisting as isolated protuberances around the vaginal orifice—the carunculae myrtiformes." Hirst: "Obstetrics," Ed. 7, p. 43, 1912.

"As a result of the distention incident to the birth of the child, the hymen undergoes pressure necrosis in various places and after the puerperium the remnants are represented by a number of cicatricial nodules of varying size—the carunculae myrtiformes. Practically speaking they are infallible signs of previous child-bearing, though occasionally they may follow the marked distention and long-continued pressure incident to the removal of large tumors through the vagina." Williams: "Obstetrics," Ed. 3, 1912, p. 33.

"Usually the hymen is more or less lacerated at the first coitus. Almost without exception it is obliterated at parturition. Thereafter nothing remains of it but fleshy tags attached about the entrance to the vagina. These are called carunculae myrtiformes. From a medicolegal point of view the absence of a hymen furnishes *prima facie* evidence only of sexual indulgence . . . On the other hand carunculae myrtiformes are undeniable evidence of a former parturition." Jewett: "Practice of Obstetrics," Ed. 2, p. 23.

Other authors could be quoted, including writers of books on legal medicine, toxicology, etc.

SHOULD THE OCULIST DISPENSE HIS OWN GLASSES?

To the Editor:—In this community it has become quite an issue to decide whether or not the oculist should dispense his own glasses. In this large city, with probably twenty opticians, only one of this number has a mechanical knowledge of the proper adjustment of frames. What we desire of the opticians is that they be able to adjust frames properly, but they do not seem to realize the importance of this.

Are the opticians the friends of the oculist or are we sending our prescriptions into the hands of the enemy? Do they find fault with the prescriptions? Do they at times alter them and have our patients call on them when changes in lenses are needed?

It is a fact that in many communities the oculist receives a percentage on his eye-glass prescriptions; others own their own stone, etc. The country practitioners desire a knowledge of frame-fitting. They are compelled to sell the glasses. Most postgraduate schools are not prepared to teach adjustment. Why not? I would like your opinion on this subject. Oculist, New Orleans.

Answer.—In the following reply the term "oculist" is used for "ophthalmologist," "ophthalmic surgeon," "physician," "doctor," etc.

This is a question that cannot be positively answered "yes" or "no," in the sense that one would be altogether right and the other entirely wrong. A number of considerations must be taken into account which have an important bearing on the question.

The oculist at present as a rule has had little or no practical instruction in the field of mechanical optics. He generally has a greater or less knowledge of physiologic optics, but even possessing an acquaintance with the mechanical part of the fitting of glasses, he would not have the time—unless his practice was very limited—to do this work properly, together with his other duties. The optician in his field is a specialist just as much as the oculist, and the work of each should be in the best interests of all concerned, entirely distinct and separate; but this is a world of compromise, and it happens that in this matter, as in most things, we are often obliged to do not what is evidently the best, but the next best; consequently in this matter of optician and oculist various compromises are adopted.

The size of the population is an important consideration. Many of the smaller cities have no competent opticians, as they could not make a living. In such cases the oculist is obliged to dispense his own glasses. Hence he should have a fair knowledge of mechanical optics and the adjustment of glasses, and should see that the lenses are properly centered, the interpupillary distance absolutely correct both for distance and near, the angle of the "bridge" correct, etc. In other words, he must do the principal part of the optician's work, and for this he is entitled to compensation additional to his regular fee for professional services. The optician who fills his prescription, perhaps in a city some distance away, may rightly allow the oculist a certain discount on the catalogue prices of his materials, which is entirely different from offering him a commission for business sent him.

On the other hand, in larger cities, in which there are generally many opticians, competition and rivalry are naturally keen. The oculist who fits his own glasses selects the optician of his choice, who in turn regards the oculist as a wholesale customer and charges the wholesale rate for his goods. The patient has no more reason to expect to get glasses at wholesale rates than he has to get his food or clothing in this way. When the oculist sends a patient away with a prescription for glasses, he must remember that his full duty to the patient and to himself has not been discharged. The patient must be requested to return to the office with the glasses so that the oculist may see for himself that the prescription has been accurately filled. This should be an invariable rule with every oculist. If the glasses are incorrect in any way, either through incompetence or from intentional alteration of the prescription, it would justify the oculist in warning his patient against the optician responsible for the error.

The best plan of all and one that would give patient, oculist and optician the greatest satisfaction, where the amount of refraction work is large enough, is for the oculist to employ his own optician as a part of his office force, and when glasses are prescribed to transfer the prescription directly to the latter. In this way the patient is not allowed to leave with the glasses until they have been thoroughly tested by both the optician and the oculist. This plan has been successfully adopted by a number of the leading oculists of the country.

In regard to the teaching of mechanical optics, it is extremely doubtful if, in the already crowded curriculum of the regular four-year course, such a branch could be added. In fact, it would be impracticable and undesirable. In postgraduate courses, however, it could and should be introduced. It would undoubtedly be a popular course, as there are always young oculists preparing themselves to settle in small communities in which refraction work will constitute the largest part of their practice and where, willy nilly, they will be obliged to dispense their own glasses. To do this intelligently, they must first have competent instruction to do the proper work of the optician. If such a course as this were introduced, it would, before long, do much toward eliminating many of the "refractionists" and "optometrists" whose knowledge is limited exclusively to the simple mechanism of refraction, but who are absolutely ignorant of the physiologic conditions or the possibilities of pathologic changes of importance. In other words, it would mitigate the present evil of oculists trying to be opticians and of opticians posing as oculists.

IS THE JOURNAL'S ADVERTISING POLICY CONSISTENT?

To the Editor:—In the Queries and Minor Notes department for Sept. 20, 1913, is an article on "another consumption vaccine." I see in the advertising section an advertisement for Dr. Sherman's vaccine and book. Now I have been tempted to send for this book *because it was advertised in The Journal*, but if he is exploiting a questionable cure for tuberculosis, may not his book be lacking in authority? Kindly state if you think it good.

M. M. S., Tacoma, Washington.

To the Editor:—In The Journal, Sept. 20, 1913, appears the enclosed advertisement; on page 979 of the same issue you have a scathing criticism of Sherman's consumption vaccine. Does this seem consistent? I am sorry to say that through this advertisement in a previous number of The Journal I was led to buy "Vaccine Therapy in General Practice" by Sherman. I would not buy it again should I be deprived of this copy, nor would I recommend it to others. Further comment unnecessary.

C. G. Menninger, M.D., Topeka, Kansas.

Answer.—Dr. Menninger's enclosure is an advertisement that The Journal has carried of the book "Vaccine Therapy in General Practice," by Sherman—the same Sherman that puts out the "Non-Virulent Tubercle Bacillus Vaccine," criticized recently. Dr. Sherman's book deals very optimistically with the subject it covers. With much of the matter it contains The Journal disagrees; much, however, is based on fairly well-substantiated scientific evidence. So far as the Sherman products themselves are concerned, some The Journal considers unscientific and open to serious criticism; others have been passed on and accepted by the Council on Pharmacy and Chemistry. Such of the Sherman products as are open to criticism, The Journal will criticize when it seems necessary; such of the Sherman products as are acceptable to inclusion in New and Nonofficial Remedies should be acceptable to The Journal's advertising pages. We see nothing inconsistent in this. The censorship of advertising is a complex problem; how complex, only those know who are brought face to face with it daily. That, in meeting this problem, The Journal never publishes advertisements that can justly be criticized is not claimed. Being human, those who manage The Journal are just as subject to error as the other fellow. It is believed, however, that there are few, if any, publications that exercise as great care in the acceptance of advertising as does The Journal of the American Medical Association.

VERMUTH

To the Editor:—What is Vermuth? I found in a German encyclopedia that it was a decoction of *Absinthia artemesia* [*Artemisia absinthium*] or wormwood in a wine. If this is true the public at large should know it. It is used in most "cocktails." If this is true it should also be kept out of the country as is absinthe.

Frank A. Glasgow, M.D., St. Louis.

Answer.—Most of the Vermuth, we are told, is obtained by macerating a mixture of herbs, among them wormwood, for a short time with an ordinary cheap Italian wine. The product so obtained, we understand, is fortified with alcohol so as to produce a product containing from 15 to 17 per cent.

of alcohol, this being practically the alcoholic strength of port wine or sherry wine. The following statement in reference to French Vermuth is taken from the *Proceedings of the American Pharmaceutical Association*, 1900, p. 448:

> "Vermuth"—Composition and Preparation.—According to a U. S. Consular Report (1899, 60 (227), 599), the production of "Vermuth" in France is almost entirely confined to Marseilles. The ingredients employed in making an extract, which, when added to wine, forms the "Vermuth," are exemplified in the following formula: alcohol, 90 per cent., 8 liters; coriander seed, 800 gm.; Greek nuts, Peruvian bark, and sweet flag, each, 200 gm.; wormwood, sharp, and Roman wormwood, each, 720 gm.; sweet marjoram and yarrow, each, 180 gm.; rose leaves, clover and Ceylon cinnamon, each, 100 gm.; dittany and angelica seed, each, 50 gm.; hyssop, 150 gm. These are digested for eight days at 120 F., then warmed moderately over a slow fire for twelve hours, the solids removed by expression, and the liquid filtered. The extract so obtained is added to wine as desired, the alcoholic strength of the "Vermuth" so produced being from 15 to 17 per cent.

The amount of wormwood contained in these preparations is probably very slight. The ruling prohibiting the importation of absinthe has not been applied to Vermuth, probably because there is not sufficient wormwood present.

WRIGHT'S STAIN—KUHNE'S ANTIRHEUMATIC REMEDY

To the Editor:—1. Kindly give me the best method in detail to make a differential stain of blood-smears with Wright's stain.

2. Can you tell me what Kuhne's antirheumatic remedy contains? It is made in Chicago.

H. J. FRIESEN, M.D., Gretna, Manitoba.

ANSWER.—1. This subject was fully considered in an article by Wright, THE JOURNAL, Dec. 3, 1910, p. 1979. Specimen smears should be fixed before using Wright's stain. The best method of fixation is the hot copper plate introduced by Ehrlich. This method is described in any of the books on diagnostic methods. For ordinary use, Engel and Cabot, in the absence of other equipment, recommend passing the smear through the flame of a Bunsen burner several times. This often yields excellent results, but is somewhat uncertain. The technic is as follows: Cover the film with a definite quantity of the staining fluid by means of a medicine-dropper. After one minute add to the staining fluid on the film an equal amount of distilled water, so that the surface assumes a metallic luster. Allow this mixture to remain for two or three minutes. Wash the preparation in water until the thinner portions become yellow or pink in color. Just when to stop washing must be determined to a great extent by the experience of the worker. When the desired amount of differentiation is reached, dry the specimen between filter-papers and mount.

2. Kuhne's rheumatic remedy has not been examined by our laboratories. From the type of advertising matter issued by this company, the product would appear to be fraudulent.

DUPUYTREN'S CONTRACTION

To the Editor:—A case for diagnosis: A man, aged 55, American, married, barber, says he has never had any sickness to amount to anything, has not missed a Saturday in all the years he has followed his trade and still enjoys good health. Several years ago he bruised or sprained the flexor tendon of the third finger of his right hand. A gradual contraction of the tendon in the palm ensued which has progressed until now the first joint is bent at right angles and cannot be extended, although flexion beyond that point is possible. Since that injury and without any knowledge of injury to the other hand, similar contractures have begun in the palmar portions of the flexor tendons of the left second, third and fourth fingers. Hard, smooth nodules are palpable along these tendons as far as the wrist, and the skin over these nodules seems to be adherent to the tendons. Occasionally he has attacks of aching pain in the hands which will awaken him at night. What is it?

X. Y. Z.

ANSWER.—This case is undoubtedly one of Dupuytren's contraction. The contracture and the nodules mentioned are not in the tendons, but in the palmar fascia.

EMBOLISM AS CAUSE OF DEATH

To the Editor:—Can you furnish me with any reprints or information on sudden death following a compound fracture of both bones of the leg, probably due to embolism?

A. E. DALE, Danville, Ill.

ANSWER.—In 1884 Fourney and von Recklinghausen first noted fat embolism as a cause of death by plugging the pulmonary capillaries. Free fat can frequently be found in the urine during the first two or three days after fracture. It is reasonable to suppose that it comes from the lacerated bone-marrow entering the circulation either directly through the torn surface or by way of the lymphatics. The symptomatology is not at all clear. On necropsy, edema of the lungs and extensive plugging of the pulmonary capillaries with free fat are found. Symptoms usually begin within twenty-four hours after the injury; rarely after two or three days.

It is the opinion of Brouardel, author of one of the very few books on the causes of sudden death, that these fat emboli are often produced by putrefaction due to micro-organisms. The larger books on surgery, particularly Stimson's "Fractures and Dislocations," give complete discussions of this subject.

REFERENCES TO FATALITIES FROM EXCESS OF ATHLETICS

To the Editor:—Please give me information concerning fatalities caused from excess of athletics.

J. L. FIELDS, M.D., Elora, Tenn.

ANSWER.—The following is a list of references on the general subject. Some of the articles may refer to fatalities:

Athletics and Health, editorial, THE JOURNAL, Feb. 8, 1913, p. 446.
Bavarian Research on Effects of Athletics, THE JOURNAL, March 22, 1913, p. 917.
College Athletics in After Life, THE JOURNAL, Jan. 25, 1913, p. 300.

Wiest, Anna: Beschäftigungsbuch für Kranke und Rekonvalescenten, published by Enke, price, 5 marks.

URIC ACID

To the Editor:—Please name the diseases in which uric acid plays a definite rôle.

H. J. LEHNHOFF, M.D., Lincoln, Neb.

ANSWER.—Uric acid is generally held to have some relation to the pathogenesis of gout. Urates are deposited about the joints in this disease, and in the early part of a gouty attack the excretion of the urates into the urine is less than the average. At a later stage a larger quantity than normal is generally excreted. It is not settled, however, that uric acid plays an etiologic rôle in the case of gout. No definite relation of uric acid to other diseases has been established.

LEAD-POISONING

To the Editor:—In a recent number of THE JOURNAL, Sept. 6, 1913, p. 773, reference is made to an article on lead-poisoning found in Bulletin 85, Bureau of Labor, Washington, 1911. I have obtained a copy of Bulletin 85, which is, however, published in 1909, but can find no such article on lead-poisoning in it.

J. W. LUTHER, M.D., Palmerton, Pa.

ANSWER.—The reference should be to Bulletin 95 instead of 85.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARIZONA: Phoenix, October 7-8. Sec., Dr. John Wix Thomas, Phoenix.

COLORADO: State Capitol, Denver, October 7. Sec., Dr. David A. Strickler, 612 Empire Building.

DISTRICT OF COLUMBIA: Washington, October 14-16. Sec., Dr. George C. Ober, 125 B St., S. E.

GEORGIA: Regular, State Capitol, Atlanta, October 14. Sec. Dr. C. T. Nolan, Marietta; Eclectic, State Capitol, Atlanta, October 14. Sec., Dr. C. W. Miller, 192 W. North Ave.

IDAHO: Boise, October 7. Sec., Dr. John F. Schmershall, Jerome.

KANSAS: National Hotel, Topeka, October 14. Sec., Dr. H. A. Dykes, *Lebanon.*

LOUISIANA: New Orleans, October 27-29. Sec., Dr. A. B. Brown, 34 Cusachs Building; Homeopathic, 702 Macheca Bldg., New Orleans, November 3. Sec., Dr. Edward Harper, New Orleans.

MICHIGAN: Capitol Bldg., Lansing, October 14-16. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.

MINNESOTA: University of Minnesota, Minneapolis, October 7-10. Sec., Dr. Thomas S. McDavitt, 814 Lowry Building, St. Paul.

MISSISSIPPI: Jackson, October 28-29. Sec., Dr. E. H. Galloway, Jackson.

MONTANA: State Capitol, Helena, October 7. Sec., Dr. Wm. C. Riddell, Helena.

NEVADA: Carson City, November 3. Sec., Dr. S. L. Lee, Carson City.

NEW JERSEY: State House, Trenton, October 21-22. Sec., Dr. H. G. Norton, 429 E. State Street.

NEW MEXICO: Santa Fe, October 13. Sec., Dr. W. E. Kaser, East Las Vegas.

OKLAHOMA: Muskogee, October 14. Sec., Dr. John W. Duke, Guthrie.

UTAH: Salt Lake City, October 6-7. Sec., Dr. G. F. Harding, 310 *Templeton* Building.

WYOMING: State House, Cheyenne, October 15. Sec., Dr. J. B. Tyrrell, Laramie.

Michigan June Report

Dr. B. D. Harison, secretary of the Michigan State Board of Registration in Medicine, reports the written examination, held at Ann Arbor, June 10-12, 1913. The number of subjects examined in was 14; total number of questions asked, 100; percentage required to pass, 75, and not less than 50 in each subject. The total number of candidates examined was 53, all of whom passed. Three candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Chicago College of Med. and Surgery	(1913) 84.4, 84.2,	87
Bennett Medical College	(1913)	88.9
University of Illinois	(1913) 81.7,	83.5
Boston University	(1899) 86; (1912)	85.5
University of Michigan, Homeopathic College	(1913) 78.6, 80.3, 82.9, 83.5, 84.4, 84.4, 85.4, 85.9, 86.5, 88, 88, 90.2, 90.9.	
University of Michigan, College of Medicine and Surgery	(1912) 81.9; (1913) 78.2, 79, 79.5, 80.1, 81.3, 81.4, 82.7, 83.7, 82.7, 83.8, 84.3, 84.5, 84.5, 85, 85.1, 85.2, 85.5, 86.1, 86.5, 86.8, 87, 87.2, 87.3, 87.4, 87.6, 88, 88.2, 88.7, 89.4, 89.4	
McGill University, Montreal	(1913)	87.5

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Northwestern University	(1882)	Illinois
Pulte Medical College	(1883)	New York
Woman's Medical College of Pennsylvania	(1902)	Penna.

Maine July Report

Dr. Frank W. Searle, secretary of the Maine Board of Registration of Medicine, reports the written examination held at Augusta, July 15-16, 1913. The number of subjects examined in was 10; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 31, of whom 28 passed and 3 failed. Four candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Medical School of Maine	(1912) 82; (1913) 81, 83, 84, 85, 89, 90, 92, 93.	
Maryland Medical College	(1912)	75, 80
Harvard Medical School	(1903) 84; (1910) 88; (1912) 84, 87, 87; (1913) 77, 83, 89.	
Boston University, School of Medicine	(1912)	76
Tufts College Medical School	(1913)	80, 84, 86, 90
College of P. and S., Boston	(1912) 82; (1913)	82
Columbia University Coll. of Phys. and Surg.	(1913)	82
Laval University, Quebec	(1913)	75

FAILED

Maryland Medical College	(1910)	73
College of Physicians and Surgeons, Boston	(1910)	66
Laval University, Quebec	(1903)	78*

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Georgetown University	(1906)	Utah
Johns Hopkins University	(1897)	Dist. Colum.
Harvard Medical School	(1898)	Dist. Colum.
University of Vermont	(1912)	Vermont

* Fell below 60 per cent. in physiology.

Alabama July Report

Dr. W. H. Sanders, chairman of the Alabama State Board of Medical Examiners, reports the written examination held at Montgomery, July 8-11, 1913. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 90. of whom 45 passed and 45 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Birmingham Medical College,	(1912) 75, 75, 77; (1913) 75, 76, 77, 77, 79, 80, 80, 81, 81, 82.	
University of Alabama,	(1911) 76; (1913) 75, 76, 77, 78, 78, 79, 80, 80, 80, 90.

University of the South	(1907)	60.

The following questions were asked:

ANATOMY

1. How are cervical, thoracic and lumbar vertebrae distinguished? Give the characteristics of the seventh cervical vertebra. 2. To what class of joints does the elbow belong? What bones enter into its formation and name three of its ligaments. 3. Name the muscles of the anterior tibial region, and describe the tibialis anticus. 4. Describe a nerve fiber. 5. Give the origin and course of the musculospiral nerve. 6. Describe briefly the structure of arteries and veins. 7. Name the branches of the external carotid artery. Give the origin, course and distribution of the lingual artery. 8. Give in a general way the flow of blood through the systemic veins. 9. Name the terminal lymphatic vessels, and locate and describe the receptaculum chyli. 10. Give the structure of the stomach.

PHYSIOLOGY

1. Discuss at length the means and methods employed by the human organism in protecting itself against infectious diseases. 2. What phenomena follow injury to and section of the pneumogastric nerve? 3. Discuss the function of the mucosa of the respiratory tract. 4. Discuss the distribution and function of the cerebrospinal fluid. 5. Discuss aphasia. 6. Discuss hunger and thirst. 7. How is the automatic action of the heart muscle supposed to be maintained. 8. Discuss the absorption of ingested fats. 9. What general conditions influence blood-pressure and blood-velocity? 10. Discuss the origin and significance of urea.

CHEMISTRY

1. Define "chemical change" and "physical change." 2. Name, describe, and give source of two elements used in their elementary forms in medicine. 3. Describe hydrogen, how does it occur and how may it be prepared? 4. Describe carbon dioxid, give formula and state what relation it bears to the respiratory changes. 5. What is phenol, give properties and source. 6. In what tissue is iron an important constituent, and how is it combined therein? 7. Define "proteid" and name three proteids found in the human body. 8. Describe the method for the quantitative determination of urea. 9. How may occult blood be detected in the feces? 10. What are ptomains and how may they be introduced into the body?

HYGIENE AND MEDICAL JURISPRUDENCE

1. Define hygiene. 2. What is immunity and how developed? What is susceptibility? 3. Give the differential diagnosis between scarlet fever and measles. 4. What effect does excessive exercise have on the heart? What effect does insufficient exercise have on the heart? 5. What is the difference between parasites and saprophytes? 6. If on examination colon bacilli are found to be present in the general water-supply of a community, what fact does it establish? What steps, if any, should be taken to protect the community? 7. Give the prophylaxis of uncinariasis. 8. What are the methods of self-purification of large bodies of water? 9. What are the symptoms of acute poisoning from bichlorid of mercury and the antidote? 10. Found, the dead body of a newborn infant. How can it be positively determined that the child was born alive?

SURGERY

1. Give the cardinal rules for treatment of wounds. 2. Give the treatment of shock and the precautions that may be taken for its prevention. 3. Name the different forms of peripheral aneurysms and give treatment for different varieties. 4. Name the varieties of fistula in ano and give treatment for same. 5. Describe the treatment of a compound fracture of the femur. 6. Give the diagnosis and tell how to reduce a backward dislocation of the head of the femur. 7. Give diagnosis and treatment of empyema, or pus in the pleural cavity. 8. Give symptoms and treatment of gall-stones. 9. Give diagnosis and treatment of perforation of the intestine in typhoid fever. 10. Give symptoms of suppurative pyelitis.

OBSTETRICS

1. What changes take place in the circulatory apparatus of the fetus after birth? 2. What conditions may be mistaken for pregnancy? 3. How would you diagnose the death of the fetus in utero? 4. What are the results of retroflexion of the gravid uterus with incarceration? 5. What are the premonitory symptoms of eclampsia? 6. What precaution should be taken in the management of face presentations? 7. What precautions should be taken against septic infection during labor and in the puerperal state? 8. Describe the internal method of performing podalic version and what are the dangers to the fetus? 9. (a) Give the diagnostic points of value in breech presentation prior to rupture of the membranes. (b) Name and describe positions of breech presentation. 10. Describe briefly the operation of cesarean section.

GYNECOLOGY

1. Give the etiology of metrorrhagia. 2. Give the effects of öophorectomy. 3. Give the names of the two most important muscles of female perineum. 4. What is meant by fibrosis of the uterus? 5. Describe the endometrium. 6. Name the conditions that cause sterility in the female. 7. What pathologic conditions are caused by posterior displacement of the uterus? 8. Classify tumors of the uterus. 9. Describe one operation for procidentia uteri. 10. Give the contra-indications for curettage.

DISEASES OF THE EYE, EAR, NOSE AND THROAT

1. In complete ptosis how is the eye, or its appendages, affected, and why? In complete facial paralysis how is the eye, or its appendages, affected, and why? 2. Give the differential diagnosis between acute catarrhal conjunctivitis and gonorrheal ophthalmia, and the general principles of management of each. Write two prescriptions for each. 3. Explain the normal reaction of the pupil. What is the condition of the pupil in iritis, and what the remedy? What is the condition of the pupil in glaucoma, and what the remedy? 4. State some conditions that would demand enucleation of the eyeball, and describe the operation. 5. Give the symptoms of complete obstruction of the eustachian tube, of some standing, and explain briefly the measures to be employed for relief. 6. Give the symptoms, dangers and management of acute purulent otitis media. 7. How would you diagnose and manage abscess of antrum of Highmore? 8 Give the symptoms, diagnosis and management of adenoids of the pharynx. 9. A person is eating and suddenly begins to struggle for breath and turns bluish in appearance; what would you suspect, and what would you do? 10. Give some of the indications for laryngotracheotomy and describe the operation.

THE ETIOLOGY, PATHOLOGY, SYMPTOMATOLOGY AND DIAGNOSIS OF DISEASES

1. Give the etiology of mucous colitis. 2. Give the etiology of scurvy. 3. Give the pathology of endocarditis. 4. Give the pathology of abscess of liver. 5. Give the symptomatology of erysipelas. 6. Give the symptomatology of heat-stroke. 7. Give the diagnostic symptoms of pellagra. 8. Name one variety of pernicious malarial fever and give its diagnosis. 9. Give the diagnosis of diabetes mellitus. 10. Give the differential diagnosis between appendicitis and ovaritis.

PHYSICAL DIAGNOSIS

1. Name points for observation in the inspection of the thorax. 2. Name points for observation in the inspection of the abdomen. 3. Give the varieties or kinds of respiratory (breath) sounds and the explanation of each (adventitious sounds not asked for, such as râles for example). 4. Give the varieties or kinds of voice sounds and the explanation of each. 5. Give the physical signs of bronchial asthma and their explanation. 6. Give the differential physical signs between a thoroughly compensating cardiac hypertrophy caused by mitral stenosis and one caused by aortic insufficiency, and the reasons for same. 7. Give the physical signs of pericarditis with considerable effusion and their explanation. 8. Give the physical signs of arteriosclerosis. 9. Give the method for the physical examination of the spleen. 10. Give the physical signs of a bladder distended with fluid. (Optional, to be answered or not, as the applicant prefers). Make a diagnosis in the following hypothetical case: Right side: Absent movement; bulging intercostal spaces; absent fremitus lower three-fourths, increased upper fourth; flatness lower one-third; tympany middle and part of upper third, dulness remaining upper third; absent respiratory and vocal sound lower third; amphoric breathing and egophony middle and part of upper third; bronchial breathing and bronchophony remaining upper third; succussion positive. Left side: Exaggerated movement and respiratory sound and apex of heart to left of mammary line.

Book Notices

PREVENTIVE MEDICINE AND HYGIENE. By Milton J. Rosenau, Professor of Preventive Medicine and Hygiene, Harvard. Cloth. Price, $6. Pp. 1074, with 157 illustrations. New York: D. Appleton & Co., 1913.

This excellent book is a distinct addition to the lengthening list of books of the first rank by American authors. Professor Rosenau's wide and varied experience and his intimate practical acquaintance with many details of public health work qualify him in a high degree for preparing a treatise on preventive medicine. The scope of the work as he has conceived it is a broad one. The book includes sections on the prevention of the communicable diseases, on immunity, heredity and eugenics, on foods, air, soil, water, sewage disposal, refuse disposal, vital statistics and industrial hygiene. Reference is made throughout to American experiences and conditions, often to the personal observations of the author, and this adapts it particularly to practical use in this country. The field covered is so extensive that the author declares "the question . . . has been rather what to leave out than what to include." Here and there irrelevant matter is allowed to usurp space needed for more vital subjects, a curious instance being the elementary physics in the paragraph on the properties of ice (page 840). The section on disinfection is especially full and authoritative, as was to be expected from the author's previous work on this subject. The section on insect-borne disease is also admirable. Very full and clear is the section on occupational disease. We do not, however, notice any reference to the recent work on the probable influence of certain occupations in causing or predisposing to cancer, as observed in the anilin workers of Basel. In the chapter on typhoid fever (page 77) the somewhat unguarded statement is made that a group of European cities with typhoid death-rates averaging 13.9 (1909) and 15.6 (1910) "would be considered low in America." As a matter of fact more than half the cities in this country with over one hundred thousand population had a typhoid rate under 13.9 in 1912. Pellagra is discussed under the head "Poisoning from Plant Foods" and, if we understand him, Professor Rosenau seems to regard the disease as undoubtedly due to the use of spoiled corn. On page 235, however, the gnat *Simulium* is pictured and is said to be "implicated in pellagra." At times the author fails to explain his meaning clearly, as when he makes the remarkable statement that "the medical sciences lost sight of heredity, owing to the ultramaterialistic view of disease which became the vogue as a result of the germ theory" (page 424). The book is marred by the frequent misspelling of proper names. A number of the illustrations are crude and some, as the picture of a laboratory hot-air sterilizer on page 981, quite unnecessary. These are obviously minor points. Taken as it stands Professor Rosenau's book becomes at once a standard authority on the subject of preventive medicine. It should find a place in the library of every worker in this field.

THE BACTERIAL DISEASES OF RESPIRATION, AND VACCINES IN THEIR TREATMENT. By R. W. Allen, M. D., B. S. Cloth. Price, $3 net. Pp. 236, with illustrations. Philadelphia: P. Blakiston's Son and Company, 1913.

The author after more than eight years of study of the bacteriology of the respiratory tract, presents in this book some interesting conclusions as the result of his experience. The findings, if correct, would establish the etiology of all common colds on a bacterial basis. He even goes so far as to attempt to differentiate from the clinical symptoms the probable class or variety chiefly responsible for bacterial affections originating in or attacking the different regions of the respiratory tract, as the nasal, nasopharyngeal or the laryngeal portions. The author is a thorough bacteriologist and seems to be conservative in his conclusions.

Interesting features of his findings are that the predominating organism in the various respiratory affections changes with time, and more recent study of the bacteriology of the upper respiratory tract reveals great differences in the findings from those of five years previous. Vaccine therapy is advocated in the treatment of all of these affections and Allen reports good results in their cure and in the matter of immunization, but the fact is emphasized that all work must be controlled by the most careful bacteriologic determinations. Immunity, he says, probably depends more on the chemical composition of the tissues, as determined by metabolic processes, than is at present realized. In the discussion of vaccine and tuberculin therapy in tuberculosis, and the findings and the effect of mixed infections, the point is made that some varieties of germs complicating the tuberculous infection have an accelerating effect on the growth of the tubercle bacilli.

As seems to be too common with English medical writers, the author here has not hesitated to mention the employment of many proprietaries, some of which are downright nostrums of the patent medicine class.

Old Age. Its Care and Treatment in Health and Disease. By Robert Saundby, M.D., Professor of Medicine in the University of Birmingham. Cloth. Price, $2.10 net. Pp. 306. New York: Longmans, Green & Co., 1913.

Why shouldst thou die before thy time?—Eccles., viii, 17.

In this time of haste and struggle the question comes very aptly. The study of geriatrics in medicine must ultimately become a field as distinct and significant as the well-established department of pediatrics. Preventive medicine by its rapid wide-spreading growth is creating a condition whereby the individual, once reaching successfully the age of puberty, passes on with but few medical intermissions to beginning old age. The steps from adult life to normal old age are inclined to come insidiously. As the breaking up of the individual begins the physician should be able to recognize the advances distinctly normal from those characterized by symptoms of disease. In this book the author points out what may be considered as normal old age. He describes the diseases to which the aged are especially liable, considering especially etiology and prophylaxis. The contributions made recently to this growing subject are included. A special chapter is devoted to dietary and general treatment, and in six appendices are given formulas, dietaries, food analyses and a table of exercises for elderly people. The author writes in a genial, retrospective manner after an experience of forty years, and the book should make very pleasant instructive reading for the physicians' leisure hours.

Disease in Milk. The Remedy Pasteurization. By Lina Gutherz Straus. Paper. Pp. 221. New York: Mrs. Nathan Straus, 27 West Seventy-Second Street, 1913.

This pamphlet constitutes a record of the philanthropic work of the late Nathan Straus in child saving, a strong argument, backed up by the record of his own work and the results of the investigations of government and other authorities, for the pasteurization of all milk used for human food, a practical guide for the establishment and conduct of sterilized milk stations, and a memorial by his widow in commemoration of his beneficences. It is intended to continue and create general interest in the work to which Mr. Straus devoted over thirty years of his life.

Minor Maladies and Their Treatment. By Leonard Williams, M. D., M.R.C.P., physician to the French Hospital. Third Edition. Cloth. Price, $2.50 net. Pp. 396. New York: William Wood & Co., 1913.

This book, published first in 1906, has undergone little change except revision since that time. The indiscriminate mention of proprietaries noted at the first review is not so striking. The general arrangement of the book remains the same and the author's revisions have in general brought the subject matter well up-to-date. It is a question whether or not all the conditions treated are in reality minor maladies. The author introduces under goutiness a discussion of high blood-pressure, and includes other important subjects under some of his titles, so that the book covers a large part of internal medicine. In the study of indigestion the author confines himself to the sphere of functional diseases. Dyspepsia is divided into two forms dependent on symptoms, but both are referred to the same cause, irritation. The stomach tube does not seem to enter into his diagnostic scheme, so that his views are largely based on purely clinical data. While such a method does not indicate strictly modern ideas, it must be admitted that the study of symptoms, while very misleading at times, has much to commend it. The reader who makes due allowance for the empirical character of the work will find much profit in its perusal.

Text-Book of Diseases of the Nose, Throat and Ear. For the Use of Students and General Practitioners. By Francis R. Packard, M.D., Professor of Diseases of the Nose and Throat in the Philadelphia Polyclinic Hospital and College for Graduates in Medicine. Second Edition. Cloth. Price, $3.50. Pp. 377, with 145 illustrations. Philadelphia: J. B. Lippincott Company, 1913.

This is a practical book for the general practitioner, the student or the physician seeking postgraduate instruction. The author goes to the heart of every subject, giving concise descriptions without the introduction of theoretical matters. The anatomic descriptions and those of surgical procedures are good, but the directions for medical treatment are not so happy. It would seem that much of the treatment of this sort is too stereotyped or is even archaic. Many proprietary drugs are mentioned unnecessarily and advised. It is believed that this feature of the book should be given a more modern, scientific tone. The book is well made and well illustrated. A few typographical errors are noted, and in the illustration on page 40 the inferior turbinate is labeled "superior turbinate." The section on tonsils and adenoids has been rewritten and a section on bronchoscopy and esophagoscopy has been added to this edition.

Nervous Breakdowns and How to Avoid Them. By Charles D. Musgrove, M.D. Cloth. Price, $1 net. Pp. 188. New York: Funk & Wagnalls Company, 1913.

On the cover of Musgrove's book some one has written, "A book of great interest and still greater importance to the general public." It is generally known that the neurasthenic delights to search through medical works for opinions as to his condition. It was to such a one that a physician once said, "Be careful, or you will die of a misprint." A considerable literature of perhaps a hundred volumes, adapted supposedly for neurasthenics, has been issued recently by various publishers. Of this type is the book by Musgrove. It is written in primer style, adapting a somewhat didactic tone, the aim being apparently to aid the man on the brink to keep from falling over. Opinions differ as to whether or not the man confronted by nervous breakdown is really helped by such literature. Of its type the book is probably better than most.

The Practice of Obstetrics. Designed for the Use of Students and Practitioners of Medicine. By J. Clifton Edgar, Professor of Obstetrics and Clinical Midwifery in the Cornell University Medical College. Fourth Edition. Cloth. Price, $6 net. Pp. 1062, with 1316 illustrations. Philadelphia: P. Blakiston's Son & Co., 1913.

The author endeavored in this edition to revise and rewrite the pathology and to add new material required to bring the work up to date. For the latter purpose such subjects have been added as blood-pressure, new ideas on anesthesia, vaccine and serum treatment of sepsis, hemorrhage of the newborn, later developments in pelvimetry, extra-peritoneal cesarean section, pubiotomy and Momburg belt constriction for hemorrhage. Many new illustrations have been inserted in this already abundantly illustrated book.

Wayside Experiences. A Collection of Plain Tales as Heard Along the Road. By C. Elton Blanchard, M.D. Cloth. Price, $1.25 net. Pp. 246. Newark, N. J.: Physicians Drug News Company. 1913.

The author has endeavored to present the experiences and observations of his professional life in a series of sketches and stories. How successful he has been, or to what extent his conclusions are sound, will depend on the point of view of the reader.

Medicolegal

Wrongly Diagnosing Case as One of Pregnancy—Insufficient Allegations to Show Malpractice—What Not Disease

(Merriam vs. Hamilton (Ore.), 130 Pac. R. 406)

The Supreme Court of Oregon reverses a judgment for malpractice rendered in favor of the plaintiff and remands the cause with directions to allow a nonsuit. The court says that the plaintiff, a married woman, averred in substance that about February 6 she employed the defendant as her physician to treat her for backache, and that he entered on such service, but did not use due care in treating her for that malady, in that he diagnosed her case as one of pregnancy, and that he contended for his diagnosis until November 8, while she was not pregnant, etc. In the consideration of the plaintiff's allegations it was of no importance whether the plaintiff was pregnant or not, for either condition is normal for a married woman who has not passed her sexual climacteric, and neither one of them is a disease or a malady. Although the complaint said that the defendant failed to ascertain the plaintiff's true condition, yet no intimation was given about what that true condition was. To charge a defendant with a tort in a case of this kind, it should appear for one thing that the plaintiff's real condition was one of disease which by the exercise of the ordinary skill of his profession the defendant should have discovered, for "they that are well have no need of a physician." In other words, if the plaintiff was in a condition of health, no cause of action would arise on the mere expression of opinion or diagnosis that she was in one or the other condition of pregnancy or nonpregnancy. In this the complaint was amenable to the objection that it failed to state a cause of action. True enough, the plaintiff said that she had a backache, but pain is not a disease; it is only the symptom of some disorder of the body which in turn may not amount to disease or trauma.

The plaintiff, indeed, said that she had been rendered weak and nervous and injured in her health and constitution by reason of the alleged careless, negligent and unskilful treatment of her by the defendant. If sound health and steady nerves were absolute conditions of every human being, it would be sufficient in so many words to charge that a departure from these conditions was due to the negligence of the attending physician, within the doctrine that it is sufficient to charge in general terms that an injury was inflicted negligently. But a continuous condition of perfect health in every or any individual does not accord with human experience, and it does not necessarily follow that the ills of which the plaintiff complained were attributable to the treatment given her by the defendant merely because they occurred during his attendance. In other words, the disorders mentioned in the complaint were such as might and often do happen to any person in the absence of medical treatment, and if the plaintiff would charge these to the defendant she must show by an appropriate averment of facts, not conclusions, that those ills were really attributable to him and would not have happened but for his lack of skill.

If we turn to an analysis of the testimony, the situation was not made better for the plaintiff. It did not establish any causal connection between the defendant's treatment of her and her alleged state of health. Out of her own mouth came statements of symptoms which all the witnesses agreed were common signs of pregnancy. She avowed that she desired to give birth to a child, and that the defendant advised her to remain quiet and take no risk of bringing on a miscarriage. She menstruated at intervals during the time she was under the defendant's care. He gave her some remedies to regulate her stomach and bowels, but the principal treatment was to advise quiet and freedom from excitement. In effect they were precautionary measures designed to prevent premature parturition.

When by lapse of time it was established that pregnancy did not exist, she consulted another physician, who diagnosed her case as one of tumor and advised an immediate abdominal operation. Not satisfied with this, she consulted still another physician, who told her there was no tumor or pregnancy and advised her to eat coarse food, put on a straight-front corset, and get rid of some of the fat on her abdomen, and the ultimate event proved the accuracy of this last diagnosis. The evidence thus disclosed that her true condition was one of health and that no injury could have resulted because of the diagnosis of her case as one of pregnancy, as that is a normal condition and not one of disease. So far as the diagnosis was concerned, no injury could be attributable to it. The bodily states of which she complained could as well be attributed to the tumor diagnosis as that of pregnancy. In this connection the trial court erred in denying the defendant's request to instruct the jury that: "Where there are two or more possible causes of an injury, for one or more of which the defendant is responsible, the plaintiff, in order to recover, must show by evidence that the injury was wholly or partly the result of that cause which would render the defendant liable. If the evidence in the case leaves it just as probable that the injury was the result of one cause as much as the other, the plaintiff cannot recover."

Treating Alleged Colles' Fracture as Sprain—Relation of Diagnosis and Treatment—Consideration of Results

(Willard vs Norcross (Vt.), 85 Atl. R. 904)

The Supreme Court of Vermont reverses a judgment for malpractice obtained by the plaintiff; dismissing the plaintiff's petition with costs. The court says that this was the third time this case had come to it from a jury trial. The plaintiff had a verdict and a judgment each time. But it was fair to presume that she had now made as good a showing on it as she ever could, and, in view of this and of the history of the case, the court thinks it ought to be ended here. The plaintiff had slipped and fallen forward onto her outstretched hands and hurt her wrists. She called the defendant in the opening of her case, and he testified that he had practiced his profession for more than twenty-five years; that he undertook the professional care of the plaintiff, and, after a careful and satisfactory examination, diagnosed a sprain of both wrists, but found no fracture; that in his treatment of her he used only one form of splint, namely, a pillow to support her hands and wrists, which were in no way bound to the pillow, but only rested on it. Other testimony on her part, given by two physicians, tended to show that she had at some time suffered an impacted Colles' fracture of both wrists.

On overruling a motion to remand the case, and dismissing a petition for a new trial, the court says that it must be admitted that there was evidence tending to show that the plaintiff's injuries were, in fact, fractures. The defendant treated them as sprains. Was he negligent in making his diagnosis? This was no more than asking if, in his effort to ascertain the character and extent of the injuries, he had and exercised the care and skill then had and exercised by physicians and surgeons in the examination of like cases in that locality. If this question was answered in the defendant's favor, liability could be established only by proof of negligent treatment; and, in proving this, it must be remembered that his mistake in the diagnosis was free from legal fault. In other words, treatment was to accord with the diagnosis; and, in judging it, it must be referred to the diagnosis, assuming, of course, that there was no negligence during the treatment in not discovering the true nature of the injury.

A physician is bound to give his patient a careful and thorough examination, so far as the circumstances will admit, using such care and skill and such methods of diagnosis for discovering the nature of the ailment or injury as are required by the rules of good local practice. If, in the exercise of such care and skill, either at the first examination or during the subsequent treatment, the plaintiff's fractures would have been discovered, the defendant's failure to discover them would amount to actionable negligence. The defendant's conduct in this behalf must be judged by what he saw and knew, or ought to have seen and known, at that time, not by what may have developed or come to light since; and, if conditions were such that the nature of the injuries became a matter of judgment merely, the defendant could not be held liable, though he erred. The conduct of a physician is to be judged, not by what usually appears and can be discovered in such cases, but by what appears or can be discovered in the instant case.

Everything went to show that this was not a usual case, but an unusual one, with conditions so obscure that the defendant's failure to discover the fractures, if, indeed, any existed, was not due to professional negligence. The court does not say that such negligence could not be established by circumstantial evidence, nor that cases might not come up in which the result itself might not afford some evidence thereof; but here the result strongly made in the defendant's favor. The plaintiff's recovery was so complete, both as regards function and deformity, as to indicate very strongly that the defendant's mistaken diagnosis, if it was such, was not due to negligence. The evidence was overwhelmingly to the effect that the result was as good as could be expected by the most skilful treatment. And the radiographs before the court showed such a complete and perfect restoration of the injured wrists that any abnormal conditions still existing were so slight as to escape the untrained eye. This result, however, was not to be taken as conclusive on the question of the defendant's liability for negligent treatment. For, though the ultimate result was all that could be expected, if the defendant negligently adopted a course of treatment which resulted in greater suffering or longer disability than would otherwise have followed the injuries, he would be liable to that extent. The question of negligent treatment, as has been seen, was to be referred to the diagnosis. If this was free from negligence, and the treatment was in accord therewith, no cause of action for malpractice existed.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

Twenty-Sixth Annual Meeting, Held at Providence, R. I., Sept. 16-18, 1913

The President, Dr. **Miles F. Porter**, Fort Wayne, Ind., in the chair.

Officers Elected

The following officers were elected for the ensuing year: president, Dr. Charles N. Smith, Toledo, Ohio; vice-presidents, Dr. Hugo O. Pantzer, Indianapolis; Dr. J. H. Branham, Baltimore; secretary, Dr. E. Gustav Zinke, Cincinnati (reelected); treasurer, Dr. Herman E. Hayd, Buffalo (reelected).

Buffalo, N. Y., was selected as the place for holding the next annual meeting.

Treatment of Puerperal Streptococcemia with Intravenous Injections of Magnesium Sulphate

Dr. **James A. Harrar**, New York: The use of magnesium sulphate intravenously for the treatment of puerperal infection was first proposed by R. R. Huggins in 1910. Later, Dr. R. W. Lobenstine tested the method at the New York Lying-In Hospital with more or less success. He effected a cure in three cases of streptococcic toxemia of the fulminating type, that is so frequently fatal, and in one case of streptococcic bacteriemia. His fifth and last case, one of streptococcic toxemia, but with negative blood cultures, resulted fatally, and rather discouraged him in the efficacy of the treatment. In continuation of this work, I have employed the salt intravenously in nine additional cases of the severer type of puerperal infection, the bacteria having been demonstrated in the blood of five.

A 2 per cent. solution of chemically pure magnesium sulphate is prepared with freshly distilled water. This is filtered and sterilized in half liter flasks in an autoclave. This solution will not hemolyze human red blood-cells, and I have found by experience that prepared in this way it will not cause any temperature reaction in the patient. Magnesium sulphate is of more value early in the course of the infection than after secondary localization has occurred. In the chronic cases of secondary thrombophlebitis or pyemia it does not appear to be of benefit. Its action seems to be chiefly on the organisms circulating in the blood. It shortens the course of the bacterial toxemias in which the bacteria cannot be demonstrated in the blood by culture, and anticipates the establishment of a bacteriemia, and finally it has reduced the mortality in puerperal bacteriemia, especially in streptococcemia, the most fatal form of puerperal infection, from 93 per cent. to 20 per cent.

DISCUSSION

Dr. **Ross McPherson**, New York City: Only one case has come under my observation, which was not a true bacteriemia, and that case did very well.

Dr. **Budd Van Sweringen**, Fort Wayne, Ind.: If it be true that the establishment of an abscess in the lung, as in this case the doctor recites, was responsible for the cure brought about, it bears out the contention of a man by the name of Fouchard, who wrote on the establishment of abscess in these conditions by the injection of turpentine into the tissues of the thigh or back or any available place. I imagine the good results reported by him at that time were due to a biologic process, perhaps the establishment of antibodies in this "fixation abscess" as he called it, and whatever the theory may be a number of cases of my own were treated in that way, as well as others I have knowledge of and were followed by improvement.

Dr. **H. Wellington Yates**, Detroit: The essayist attaches very little importance to the toxicity of magnesium sulphate. In the report of his cases I find that in each instance in which the magnesium sulphate is injected there followed a distinct chill with rise in temperature. Therefore, magnesium sulphate should be used with care.

Lactation Atrophy of the Uterus

Dr. **Douglas H. Stewart**, New York City: With lactation atrophy the breasts either produce too much mammary extract, and the uterus wastes away, as a fibroid sometimes will when powdered cow's udder is administered, or the secretion drains off, in the milk, some hormone which should stimulate the circulation, nutrition and growth of the uterus after the normal or physiologic atrophy of the fifth month of lactation, and the physiologic process becomes pathologic in time. In one case in my series I made the circulation right. After that lactation ceased, and growth and menstruation started at once.

DISCUSSION

Dr. **Ross McPherson**, New York City: I have wondered whether this secretion present in the breast was not the secretion that we find in many cases of pelvic disturbance. As soon as the disturbance in the pelvis is relieved, the secretion disappears. The condition is interesting and rather unusual. I had not before seen a case of lactation atrophy that presented such symptoms.

Dr. David Hadden, Oakland: In a case in which I operated two years ago there was no lactation connected with the menstruation. The woman had a baby four years before the time I saw her and had not menstruated. The uterus was retroverted, and both ovaries were prolapsed. There was a deep laceration of the cervix and an ulcer. We corrected these conditions, and two months after operation she began to menstruate and has since menstruated every month, the flow being practically normal.

Dr. Hugo O. Pantzer, Indianapolis: The paper calls attention to a class of cases touched on too little in medical literature. About twenty-five years ago I confined a blonde who had all her previous life been in frail health. After being married for one year she conceived and had a child at full term. It was a forceps delivery. There were no complications incident to child-bed. The child, in contrast with the mother, thrived wonderfully and was nursed for two years. The family was very anxious to have offspring, and the woman came to me at about the third year. I found a small atrophic uterus and complete amenorrhea of some year's standing. It is fair to associate amenorrhea and atrophy of the uterus with excessive lactation. General remedies and the use of an intrauterine stem for a period of three or four months brought back menstruation, and the patient conceived again.

Treatment of Placenta Praevia by Cesarean Section

Dr. Ross McPherson, New York City: Since 1891, in the service of the New York Lying-In Hospital, there have occurred 470 cases of placenta praevia, and the operation of cesarean section has been performed for this condition nineteen times by six different operators, all since 1905. The situation of the praevia was central in nine cases, marginal in five cases, and no statement as to situation was made in the history in five cases; no case with more than two fingers dilated; all had had severe hemorrhages before entrance into the hospital, and in all it was a matter of rapid delivery being considered advisable. The patients varied from para 1 to para 14; the youngest was 18 and the oldest 38. As to results, of the nineteen cases operated, one mother died, a maternal mortality of 5.3 per cent., two children were stillborn, and three died before leaving the hospital, two on the first day, and one on the ninth, a fetal mortality of five, or 26 per cent.

I believe that the indication is clear, that when we encounter a primipara with a placenta praevia either marginal or central, or a multipara, with a central placenta praevia, in either case where the cervix is rigid or undilated, whether or not there is pelvic disproportion, provided the child is viable and the mother offers the ordinary safe operative risk, cesarean section holds out a better chance of saving the lives of both mother and child with fewer complications than any other method of delivery, always provided that the operation is performed by a competent and experienced operator and amid suitable surroundings.

The Advantages of Cesarean Section Over Other Procedures in Border-Line Cases

Dr. John Wilson Poucher, Poughkeepsie: In five cases of cesarean section I used the high abdominal incision, opening the uterus *in situ* as soon as it is exposed, carrying the uterine incision well over the fundus. With this incision the operation can be done through an abdominal opening about one-half the size of the lower incision, and the abdominal and uterine wounds are separated by the contraction and involution of the uterus. Another advantage is that the uterine incision is made through a part of the organ away from the larger blood-vessels, and hence there is less danger of hemorrhage, and I believe also a portion of the uterus less likely to rupture in subsequent labors. For protecting the intestines and to absorb any fluids which are likely to overflow, one or two gauze pads, six inches wide, six or eight feet long, are useful. It has been said that cesarean section has caused a considerable number of ruptured uteri. We can safely say that timely cesarean section will prevent most, if not all, ruptures.

DISCUSSION

Dr. Charles N. Smith, Toledo: I have done twenty-three abdominal cesarean sections. Two of these were done in the presence of placenta praevia centralis, one of them particularly for that sole indication, and the other in the presence of transverse presentation in a woman who had lost three children previously in labor and who solicited this cesarean section. The first case was a woman, 20 years of age, who was seen at St. Vincent's hospital, having had a profuse hemorrhage. She was a primipara, with a very small vagina, long, conical, rather firm cervix, with not much dilatation, and placenta praevia centralis. We did an abdominal cesarean section immediately and saved the mother and child.

The second case was a woman, 32 years of age, on whom I did a cesarean section last May. She had been confined previously at three different times, once with a transverse presentation, the others with breech presentation. In the transverse and one breech presentations the child was delivered dead. In a third breech presentation, the child lived for some few moments only. If she had a head presentation, it was thought best to deliver by forceps. If she had an irregular presentation, or if there were any complications which led us to believe she could not be safely delivered of a living child, cesarean section must be done. Arrangements were made to take her to the hospital to have this operation done. She was taken with slight pain and profuse hemorrhage in the night, and I was quickly notified and called to see her. I found her with very little pain, with dilatation of about an inch, the head in the left iliac fossa, the back and occiput anterior, and the placenta seemingly occupying the entire lower segment of the uterus. She was bleeding rather profusely, although the pains were not hard. She was taken at once to the hospital; we did a cesarean section, delivered her of a living child, and saved her life. We had in that particular case what I hold to be the proper indications for cesarean section for placenta praevia and some other indications.

Dr. James A. Harrar, New York City: I have done cesarean section with perfect satisfaction in twenty-three cases, following Dr. Davis' incision

Dr. H. G. Partridge, Providence: I have never seen a cesarean section done for placenta praevia. I have seen cases of placenta praevia that showed a long, rigid cervix, but these have been very few. Practically all the cases I have seen have had a soft, boggy, easily dilatable cervix, and within my own personal experience there has been no case which would have been suitable for cesarean section. Within a week we had a case in the Lying-In Hospital in Providence which would have been ideal for vaginal cesarean section. This operation was eventually done, the mother being in good condition afterward, but the baby was born dead.

Dr. E. Gustav Zinke, Cincinnati: There is no doubt that the majority of cases of placenta praevia can be relieved successfully, both mother and child, by the Fry method or the De Lee method, by balloon dilatation or even by metal dilatation, although I have very little use for the latter. When we are able to watch these cases and have them in surroundings that are aseptic in character, we can see what we can accomplish by way of artificial dilatation and deliver *per vias naturales*, but when we have a case of placenta praevia centralis, for instance, which is usually complicated by an oblique or transverse presentation, the tampon will do no good, and before you succeed in dilating the uterus successfully, either by the tampon, balloon, by manual or metal dilatation, the woman is usually so exsanguinated that if she does not die during the process of delivery, she will die soon after delivery, and the child, as a rule, is lost under these circumstances because it means version of the after-coming head. Besides, in primiparous women with these oblique presentations, I would not attempt anything except a cesarean section. There are cases of marginal and lateral placenta praevia in which the hemorrhage is sometimes exceedingly difficult to control, and these are the cases in which a pathological condition pertains, in which the placenta is so implanted within the uterine wall that it has taken up much of the uterine musculature. Under normal circumstances the uterine wall is the same in every part, even under the placenta site. Ordinarily the placenta does not occupy the muscularis at all, but only the serotina. In those cases the hemorrhage is not very excessive and it can usually be controlled; but when the placental tissue and villi have buried themselves into the musculature, then we have trouble in controlling the hemorrhage, and a timely cesarean section will save both mother and child, while with the other manipulations you will probably have a fatal result so far as the child is concerned, and in many instances the mother is not saved.

No man has a right to make a cesarean section who is not thoroughly familiar with the technic of the operation. Every case of placenta praevia is a surgical one from the start and belongs to the hospital as truly as a case of appendicitis or any other surgical case, and there is no reason why these patients should not be sent to the hospital, even though the hospital may be 10, 20 or 50 miles away.

Rupture of the Symphysis Pubis in Labor

Dr. Henry Enos Tuley, Louisville: Careful research shows that there is but one case in from 30,000 to 60,000 births, including spontaneous and traumatic varieties. While recent writers state that there are about 150 recorded cases in literature, these figures cannot be verified, and Kayser's estimate of about 130 cases, plus those since recorded, would indicate that the more correct estimate is about 140. It may be safer to state that the estimate varies from 140 to 150. It has long been the teaching that the articulations of the pelvis become softened and relaxed during gestation on account of the secretion from the synovial membrane lining their surfaces. The extent to which this softening occurs is not stated by the authors who refer to this phenomenon. I do not think it is so great as to cause difficulty in standing or walking in very many cases, at least such a condition has never been brought to my attention. The percentage of cases of rupture which are caused spontaneously varies much according to different authors.

Complications may occur in the form of rupture of the anterior vaginal wall, rupture of the bladder, severe hemorrhage from rupture of the veins about the vestibule, or suppuration of the joint or soft parts. I had one case of rupture of the symphysis pubis in labor.

Conservatism in Operations for Acute Inflammatory Pelvic Disease

Dr. Budd Van Sweringen, Fort Wayne, Ind.: One should not allow a large pelvic exudate or a tubo-ovarian abscess to remain until absorbed, as it means chronic invalidism. Pus should be evacuated as soon as it is safe to do so. But when once inside the abdomen for this purpose, it is wrong to think that all pathology present must be removed with the knife. Ample provision for drainage and the ablation of the original focus will be sufficient and save many a tube and ovary, which will result in much greater peace and happiness to the patient.

Significance of Hematuria and Its Management

Dr. J. Garland Sherrill, Louisville: According to its causation, hematuria is classified as (1) traumatic, including accidental injury and also the minor traumatism resulting from stones. (2) Inflammatory, including acute nephritis, chronic inflammatory affections of the kidney, tuberculosis, acute and chronic inflammation of the pelvis of the kidney, ureter, bladder, prostate, and also of the urethra. (3) Vascular, blood dyscrasia, such as hemophilia, etc.; nevi, venous obstruction of the kidney; varicosity of the vesical veins, especially that due to prostatic engorgement. (4) Chemical, in which class should be placed hemorrhages from irritating drugs, as turpentine, cantharides, etc. (5) Toxic, in which the hemorrhage is the result of vascular changes occurring in severe toxemias, such as those resulting from malaria, acute yellow atrophy of the liver, yellow fever, scurvy, etc. (6) Neoplastic. (7) Parasitic. Renal hematuria is probably the form most interesting to the surgeon. Laceration of the kidney, gunshot and stab wounds, frequently cause hemorrhage which appears in the urine. Tuberculosis of the kidney presents hematuria as an early symptom, the amount of blood varying very greatly in different cases. In the treatment of hematuria, rest is of the greatest importance, and I advise the use of turpentine in small doses. Calculus, tumors, major traumatism and unilateral tuberculosis will demand operative intervention.

Acute Unilateral Hematogenous Nephritis

Dr. Curtis S. Foster, Pittsburgh: In the acute cases, with multiple miliary abscesses, and from which an overwhelming toxemia results, nephrectomy must be the operation of choice, if we would save the patient's life. Of the fourteen cases of this type encountered by Brewer, two were untreated, and in four nephrotomy with drainage was done. They all died. The remaining eight were treated by nephrectomy with recovery in each case. In the acute diffuse inflammation of the kidney, the treatment is not so well defined and must depend more on the course of the disease in the individual case. In those cases where the areas of infarction are very numerous, to such an extent that the function of the kidney is seriously impaired, and when the toxic symptoms are very pronounced, nephrectomy should be the operation of choice. In cases where the infarcts are few in number, the toxemia is mild, and the general condition of the patient good, splitting of the capsule with drainage of the diseased areas should be considered. Cases are on record, however, in which the symptoms have recurred after this operation and in which a subsequent nephrectomy was necessary.

The Diagnostic and Therapeutic Value of the Renal Catheter

Dr. K. I. Sanes, Pittsburgh: The value of the ureteral catheter in the diagnosis and treatment of urological disease is well established. It behooves us all to make use of it more frequently than it has been our custom in the past. To some of us ureteral catheterization seems a difficult procedure; to others a dangerous one. It should be neither dangerous nor difficult in the hands of men practicing the surgery that we do. Those who have catheterized many hundreds of ureters have learned not to fear infection from its use, and have gradually extended the field of its application with great satisfaction to themselves and great benefit to their patients.

Renal and Ureteral Calculi

Dr. Henry Dawson Furniss, New York City: Renal and ureteral calculi are more frequent than is generally supposed, and often exist, especially calculi, in the renal cortex for a long time without symptoms. The classical text-book symptomatology of calculi is oftentimes associated with other conditions of the urinary organs. The effect on the kidney of calculi is dependent on the size, shape, character, and most of all the location of the stones, those in the pelvis of the kidney and the ureter causing most damage. For those calculi that cannot be attacked from the vagina or bladder, the best procedure in stones that will be difficult to locate is the combined intra- and extra-peritoneal operation. If they can be easily found on account of their size, I would prefer the extraperitoneal route. It is not necessary to close the ureter, as it heals rapidly. A cigarette drain near the ureter had best be used for seventy-two hours, or while there is still drainage. If the stones are to be felt through the vagina, they can be removed through it; if impacted in the vesical orifice, by slitting the ureter through an operating cystoscope, or after suprapubic cystotomy, or by cautery fulguration.

Local Anesthesia in Abdominal Surgery

Dr. Julius H. Jacobson, Toledo: With this method of local anesthesia I have performed thirty-six operations on twenty-eight patients, eight of these being operated for double hernia. The operations were as follows: twenty-eight operations for radical cure of inguinal hernia; three operations for strangulated inguinal hernia with radical cure; one operation for radical cure of femoral hernia; two operations for strangulated femoral hernia; one operation for incarcerated umbilical hernia; one operation for incisional hernia; total number of operations on twenty-eight patients, thirty-six. Mortality, 0 per cent.

In only two of the earlier operations was it necessary to finish the operation under a general anesthetic. This was due to inexperience with the method. The operations were uniformly painless, without nausea or vomiting, and without the slightest toxic effect from the anesthetic solution. The sensation of the operation is described by the patients as that of a pulling or tugging on the parts. In a few instances some pain was complained of when working about the hernial sac or peritoneum. This can be overcome by a separate injection of the neck of the sac early in the operation. As the adrenalin acts as a hemostatic, there is some danger of a postoperative hematoma. It is therefore, necessary to ligate all blood-vessels as soon as they are divided.

Cholangitis and Pancreatic Lymphangitis

Dr. L. W. Swope, Pittsburgh: The clinical histories and physical signs in twenty-two cases out of a series of 2,000 operations on the biliary and pancreatic systems justified the diagnosis of carcinoma of the head of the pancreas. The findings were of such a nature that differentiation from cancer is almost impossible. There was recovery with relief of symptoms after temporary or permanent drainage of the bile passages which excluded the possibility of malignancy. At necropsy on the three patients that died, the postoperative and post-mortem changes were so marked, the characteristic operative findings were completely altered; consequently, post-mortem examination has added very little to our knowledge of pancreatic lymphangitis. It is probable that the infection causing the pathologic enlargement of the head of the pancreas in these cases travels through the lymphatics, causing lymphangitis in the pancreatic interstitial tissue. This supposition explains the improvement and cure with the subsidence of the inflammatory enlargement of the head of the pancreas which follow operation. The origin of infection is often obscure.

Treatment consists in drainage of the bile passages, temporary or permanent. The former is obtained by surface drainage of the gall-bladder and common duct; the latter, by anastomosing the gall-bladder to the duodenum or stomach.

Observations Based on Seventy Cases of Bowel Obstruction with Special Reference to the Unusual Cases

Dr. Walter C. G. Kirchner, St. Louis: Obstructions due to hernia were encountered in forty-seven cases, or in 10 per cent., of the hernias operated on. Most of the cases of ileus were seen in the critical stages, and the mortality rate was 52 per cent. In the seventy cases postoperative ileus due to adhesions occurred ten times, with a mortality of 50 per cent. The appendix was implicated in 8 per cent. of the cases. Resection of bowel was performed in 25.7 per cent. of the cases, with a mortality of 27 per cent. The intestinal obstructions which were encountered were those caused by adhesion, carcinoma, fibromyoma, intussusception, volvulus, interstitial hernia, excessive dilatation of colon, gall-stone, prolapse of intestines through rupture in mesentery, prolapse of intestine through rent in omentum, thrombosis of superior mesenteric artery, etc.

Obstruction of the bowel is essentially a surgical condition, and the mortality rate is in direct proportion to the duration of the obstruction. Greater stress should be laid on the necessity for early operation in bowel obstruction. In the early cases of obstruction, resection may be a safe procedure, while in the critical cases primary enterostomy and later resection of bowel or repair of fecal fistula is a better course to pursue.

Cancer of the Uterus and Fibroid Tumors from a Clinical Standpoint

Dr. Edward Joseph Ill, Newark: From personal experience, I hold that fibroid tumors are not a cause of malignant degeneration of the uterus. Among 443 operative cases in my own hands there is no record of any fibroid having undergone malignancy, nor is there any record among 2,600 cases recorded in my office case book of any having undergone malignancy, although many of these cases were seen repeatedly for years. The necropsy records of hospitals variously situated show that from 4 to 8 per cent. of all women over 30 years have fibroid tumors. During the same time that the 443 operations of fibroid tumor took place, I operated on 175 cases of cancer of the uterus. Five of these cases had fibroids in the uterus; four were cases of true carcinoma; one case, a sarcoma, had small fibroids in the posterior wall, while the sarcoma was situated in the anterior wall behind the scar of an old fixation operation. It is thus shown that all my cancer cases had but 2.8 per cent. of fibroids, which is less than the average of all women over 30 years. My deductions are that we have no right to suggest the operation for removal of fibroid tumors when possible future malignant degeneration constitutes the only indication.

2 **Prenatal and Neonatal Lung.* W. H. F. Addison and H. W. How, Philadelphia.
3 Development of Cerebral Ventricles in Pig. C. H. Heuser, Boston.

2. Prenatal and Neonatal Lung.—According to Addison and How, during prenatal life the future respiratory passages are filled with a liquid. With the first inspirations of air, the thoracic cavity is enlarged by the action of the respiratory muscles, the lung is thereby enlarged, and the liquid in the trachea and bronchi is drawn down into the lung, and is distributed along the walls of the alveolar and other spaces. In microscopic sections of lung taken from fetal animals, there is seen a finely granular substance (a precipitate from the fluid present) widely scattered through the spaces; and large mononuclear cells, probably phagocytic in function, are found uniformly distributed in small numbers. In sections of lung of neonatal animals the finely granular substance is still found, usually close to the walls of the air-spaces and fewer mononuclear cells are seen. Before breathing, the lining epithelial cells of the alveoli are irregularly cuboidal with rounded nuclei; but after breathing, with the increased area of the walls of the alveoli, the nuclei are spaced farther apart, the cytoplasm is drawn out and the cells are very thin and flat. After breathing has begun, the mesenchyme appears denser, with its nuclei more compacted, and the blood-vessels are distended and more conspicuous.

30. **Diabetes in Early Infancy.**—In connection with the report of an instance of diabetes mellitus in early infancy, Knox presents briefly other cases of the same disease occurring during the first year of life. The urinary findings are usually incomplete, but a consideration of all the symptoms given warrants the probable diagnosis of diabetes mellitus in the cases of fifteen additional babies under one year reported from 1852 to the present. The majority of these cases were males. Knox found that heredity seems to have played but little part. Continuous over-feeding of sugar preceded the onset in three cases. Injury to or alteration of the central nervous system was often associated with the beginning of the malady. The more common symptoms were increased thirst and hunger, loss of weight, polyuria and glycosuria; acidosis and coma occasionally ended the scene. Knox regards the prognosis as grave, but not hopeless, even in infancy, except in a severe grade of the disease. He insists that treatment should be begun early, and, although more difficult in carrying out, should follow the lines found most successful in the treatment of diabetes in adults, i. e., the patient's carbohydrate tolerance should be determined and the sugar content of the diet (milk mixture) correspondingly reduced, the calorific requirements being furnished by fats and proteids. An "oatmeal day" or days should be given at frequent intervals.

35. **Artificial Pneumothorax in Pulmonary Tuberculosis.**—Rothschild believes *now that it is well* worth while to try an artificial pneumothorax in all one-sided cases of tuberculosis in which no improvement seems to take place under the ordinary treatment, and in which the inflation is possible, that is, where the adhesions are not so extensive that they prevent an inflation and compression. If the patient shows signs of improvement under the treatment with artificial pneumothorax, keep it up; if not, do not *reinflate.* The same principle should be followed in regard to the other side —in case this should be slightly affected. If it should improve through the increased aeration, which the compression of the *other side* necessitates, keep up the artificial pneumothorax on the bad side; if it should get worse, interrupt the treatment. Roentgen rays will not help much and are often hard to use continually. The proper physical examination in connection with careful clinical observation has been sufficient in all cases to guide Rothschild correctly.

37. **Fractured Charcot Hip-Joint.**—To cure such a fracture, Brown says, the hip-joint must be obliterated—an arthrodesis must be performed. Success is to be gained only by excision of the entire capsule and synovial membrane, complete removal of the cartilage bearing bony structure from the head of the femur and from the acetabulum and cutting away of all excess bone. To secure firm bony union the neck of the femur must be nailed to the acetabulum. The reduction of the fracture and the maintenance of the fragments in apposition is likewise attained by this last step as the nails are driven through the neck in a direct line from the base of the great trochanter. The steps in the operation are: (a) A large U-shaped incision is made over the hip with the trochanter in the center of the U. (b) With a chain-saw, the trochanter is sawed off downward and outward and then retracted with its attached muscles upward. (c) The obturators and pyriformis muscles are divided and ends transfixed for subsequent approximation. Free access is now had to the joint to permit of the removal of the capsule and cartilages.

53 Hemorrhage in New-Born. M. T. Goldstine, Chicago.

52. **Intestinal Sutures.**—Nine varieties of suture materials were used by Courtenay in his experiments, as follows: human hair, horse hair, linen, plain and paraffin; silk, Nos. 7 and 13; catgut, Nos. 00, 1 and 2. In ten dogs the abdomen was opened, observations made and the specimens removed at the end of twenty-four hours; in another ten at the end of forty-eight hours, and in the third ten at the end of ninety-six hours. Each dog was subjected to at least one kind of material, and in some instances two different kinds were used in the same animal. None of the animals died, and in none was there any marked degree of peritoneal infection. The ideal result, he says, is that in which there might be a perfect coaptation without reaction, and this is most nearly approached by using human hair as a suture. Since the amount of reaction is closely related to the amount of seepage and leakage, both of which are greater with the heavier sutures, Courtenay concludes that the finer the suture the better the result. Human hair withstands a tremendous pressure, whereas the heavy catgut invariably cuts through the bowel. Safety of result lies not in the inherent strength of the suture, but rather in the perfection of approximation and minimum of reaction. From a clinical standpoint the suture of choice is that which is of a fine texture, readily prepared and the finest that can be conveniently employed by an individual operator.

70. **Simple and Safe Method of Preparing Catgut.**—In Barbour's method the raw catgut is cut in 18-inch lengths. Each length is wound on a glass tube three-fourths inch in length. Get tubing that is used as water-gauges in steam boilers, and have them cut up in proper lengths. The gut is so wound on this tubing that the first turns fasten each end of the ligature to prevent unwrapping. The winding should be done smoothly, not allowing one turn to overlap the other. It is next placed in a solution composed of 1 part of tincture iodin in 15 parts of 90 per cent. alcohol, where it remains for ten days. At the end of ten days it is placed in a 2 per cent. watery solution of formaldehyd for twenty-four hours to render it somewhat harder, after which it is stored in 95 per cent. alcohol to which ½ grain of mercuric chlorid has been added for every ounce of alcohol. If desired it may be rinsed in sterile water before use. Barbour has soaked coils of catgut in a bouillon culture of anthrax, placed them in iodin solution and made cultures daily, and has found the gut sterile after the seventh day. He has not been able to detect any change in the catgut after it has been stored for six months. It has given good satisfaction in general surgical work and for skin sutures.

71. **Protozoan Protoplasm as Indicator of Pathologic Changes.**—An attempt was made by Woodruff and Underhill to demonstrate the existence of chemical changes arising from pathologic conditions by determining the effects of normal and pathologic tissue extracts on a unicellular animal, paramecium. To initiate an experiment a single paramecium was isolated with a capillary pipet under a Zeiss binocular microscope and placed in a watch glass with a small amount of culture medium (hay infusion) similar to that employed for the main lines of the race. When, in the course of a few days, this animal by division had produced a sufficient number of cells for the experiment each of the organisms was isolated on a clean depression slide and supplied with five drops of the extract to be tested. Each extract was tested on eight lines of sister cells for five days. Every day a single animal was isolated from each of the lines, placed on a clean depression slide and supplied with five drops of the extract from the test tube containing that day's supply.

At the time of isolation a record was made of the number of divisions in each of the eight lines of cells during the previous twenty-four hours and these data are the basis of the results submitted in the present paper. These, in brief, are: Paramecium fails to indicate any essential difference in its division rate when subjected to the influence of extracts prepared from the separate kidneys of one rabbit or from kidneys of different individuals. Kidney extracts made from a starving rabbit behave in a manner identical with normal kidney extracts of well-fed animals. The division rate of paramecium is markedly depressed when placed in kidney extracts of rabbits with tartrate nephritis. It has been demonstrated that this depressant influence cannot be associated primarily with tartrate which has accumulated in the kidneys, since quantities which could be present according to chemical tests would produce the opposite effect, namely slight stimulation of the division rate. Moreover, the depressant action of kidney extracts prepared from animals receiving large doses of tartrate is no greater than with extracts of nephritic kidneys of animals that had been given small doses of tartrate. From these facts it is apparent that the pathologic change—hence, presumably chemical alteration—in the renal tissue itself is responsible for the action observed on the division rate of paramecium.

The authors conclude that paramecium, therefore, may be regarded as a biologic indicator of chemical change; and it is proposed to employ this biologic method for the detection of chemical change under a variety of normal and pathologic conditions.

72. **Idem.**—In certain concentrations extracts of carcinoma of the breast showed a very pronounced depressant influence on the division rate of paramecium when compared to that obtained with paramecium bred in normal mammary tissue extract. In some instances the depressant influence may be so profound as to lead to the death of the paramecia within two or three days. Weaker dilutions of the abnormal tissue extracts may show a stimulating action on paramecium. It has been demonstrated that the difference in concentration which may exist between the normal and abnormal breast tissue extracts cannot be held responsible for the detrimental action of the abnormal extract on paramecium, for when the concentrations of the two extracts under discussion are made as nearly equal as possible the original type of action still is observed.

81. **Determination of Urea in Blood.**—The blood is drawn in the usual manner and allowed to stand on ice until clotting is complete. As shown below the urea content of the serum does not change after standing even for three or four days; the blood can, therefore, be kept on ice over night, if desired. Two equal portions of the serum are measured into ordinary test-tubes, 1 c.c. of the soy bean extract added to one tube, and about 0.5 to 1.0 c.c. of toluene to each. If sufficient serum is available, 10 c.c. portions should be used; however, perfectly satisfactory results can be obtained by using 5 c.c. or even 3 c.c. portions of the serum. The tubes are tightly stoppered, and allowed to remain at room temperature until the conversion of the urea into ammonium carbonate is complete. Generally, they are allowed to stand over night,

although four to five hours is usually amply sufficient for the completion of the reaction. The contents of the tube containing the serum and extract are transferred to cylinder A, and washed in with a very small amount of water (not more than 5 c.c.). Two grams of sodium chlorid, an equal volume of alcohol and a layer of kerosene oil are added to the cylinder. The contents of the other tube are transferred to cylinder B and treated in exactly the same manner. Twenty-five c.c. of N/50 hydrochloric acid and about 25 c.c. of water are placed in each of the 200 c.c. Erlenmeyer flasks used for the absorption of the ammonia. The different parts of the apparatus are now connected and about 0.5 gram of sodium carbonate added to each cylinder. A rapid air current is passed through the apparatus until all the ammonia has been removed from the cylinders. With a good suction pump, one hour suffices. The excess of acid in the absorption flasks is titrated with N/50 sodium hydroxid and alizarin sodium sulphonate. The amount of acid neutralized in the flask attached to cylinder B corresponds, of course, to the ammonia present in the serum, while the amount used in the other two flasks represents the urea plus the ammonia. The difference corresponds to the urea in terms of N/50 hydrochloric acid, and multiplied by 0.0006 gives the urea in grams present in the amount of serum taken for the determination.

93. **Anaphylaxis and Asthma.**—During the past four years there have been examined in the Mayo Clinic about 300 cases of asthma. Matthews says that *in over 90 per cent.* of the cases the principal lesions which might be considered as etiologic were in the upper respiratory tract. Chronic suppuration or the retention of mucoid secretions in the nose or accessory sinuses occurred in the majority of these cases. Treatment was directed toward the object of securing free and continuous drainage of every portion of the tract and little attention was paid to possible reflex factors of etiology. In the majority of the cases the *relief of the asthma* corresponded almost exactly with the degree of success in obtaining the result sought, that is, the prevention of the retention and reabsorption of mucous secretions. Matthews states that the relief of asthma by any known treatment does *not mean* that the patient is permanently cured, since the susceptibility remains throughout life and symptoms will recur whenever there exist conditions favorable to the production and absorption of the specific antigen to which the individual is sensitive. Various methods of desensitizing animals have been discovered but no method yet reported gives a lasting immunity and all are attended by high mortality. Until a safe and efficient method of desensitization is possible the treatment of asthma must be directed as in the past to the relief of symptoms by whatever measures are indicated in each individual case.

108 Nitrogen Poisoning. J. J. Gaines, Excelsior Springs.

101. **Diet in Habitual Constipation.**—The keynote of diet, for habitual constipation, Bell says, is the selection of foodstuffs containing a large amount of cellulose—woody fiber, which does not digest, but reaches the colon as cellulose—and those foodstuffs which leave distinct bulk of residue, so as to gently stimulate weakened muscles and blunted nerve reflexes. And they must be eaten in abundance, for constipation exists frequently as the result of a too abstemious diet, even with the colon and the rectum normal. Consequently those foods which are capable of complete digestion and leave little or no residue, such as rice, mashed potatoes, white bread and tender meats, must be used very sparingly. Some discrimination must be exercised even with coarse vegetables; and those essentially flatuous—boiled cabbage and cauliflower—must be excluded. Cabbage, raw, in the shape of cold slaw, may be used; being largely indigestible, its food value is diminished, but the cellulose content furnishes peristaltic stimulation. Bran in some form is to be used every day, either dry with cream and sugar as a breakfast food, or made into muffins, or made into bread. If it is not well tolerated, pumpernickel may be substituted, preferably a day or two old; it must be well chewed. Fletcherism is not advocated, since the degree of mental concentration involved is apt to act perniciously, especially with the neurotic. To complete the breakfast, an egg may be added, with fried potatoes and fruit, preferably fibrous—figs, dates, raisins. In regard to eggs, if there be a distinct indicanuria, animal food of all kinds, except butter and cream, is interdicted for one or two weeks.

If there be a neurosis or hyperchlorhydria, coffee is cut off indefinitely, and no fluid but cold water is permitted. The mid-day meal is made up of vegetables, nutritious, yet *containing as much cellulose as possible*—peas, beans, corn, turnips, parsnips, with whole wheat bread and fresh greens; if in season, lettuce, spinach, celery and cold slaw. Fruit is preferable for dessert to pastry or pudding. Juicy fruit, or fruit salads are allowed. The diet list must be liberal, otherwise appetite fails and the desired result is lost because of lack of bulk. For the evening meal, fruit alone is most effectual, unless the patient be a mechanical artisan or a laborer, in which case the noonday list may be repeated. An evening meal of an orange or two, with apples, figs, dates, raisins and fruit salad is satisfying to the appetite and body and aids peristalsis materially. A whole wheat or bran muffin may be added, also cold slaw or lettuce.

The general objection of insufficient caloric value is without *foundation* in Bell's experience, for this very outline is followed in his practice with excellent results. Calories may be increased by means of added butter and cream. The albuminous content may be well *maintained* by increasing the whole wheat, peas, beans and corn. The only possible objection to be made is the lack of stimulation suffered by abstinence from animal food. This is *not* complained of for a week, or two, in most cases. When it is so, animal food may be added to the mid-day meal. Such a diet as suggested will make four to five stools daily with some patients, while with others no more than one. Liberal meat eaters sometimes complain of being starved, but the impression is largely mental, for they lose *no* weight or strength. Coffee is *not* to be condemned categorically. There are cases in which coffee creates enough peristalsis for a liberal stool at once after breakfast; when this is the case, unless there be hyperchlorhydria or neurosis, it is permitted once daily. After a period of from one to two weeks, when the coated tongue and malaise have disappeared, when headache and dizziness have gone, when clear mental and physical vigor return and a habit of two or three daily stools is inaugurated, the diet list is made more liberal.

103. **Surgery and Constipation.**—The tendency at the present time, Hertzler believes, is to apply surgical procedures for the purpose of lessening the resistance to a peristaltic force which has become permanently weakened. However, before a condition becomes surgical it must have been determined that the gut force is permanently weakened, and at the present time we are not able to do this with any degree of certainty. When we come to recognize clearly, he says, that there is no anatomic basis for this class of constipation, we may be able to come to some decision as to when an alteration of anatomic conditions is indicated for the purpose of lightening the burden of a weakened gut. Obviously, such an indication cannot be formulated until the exact factors active in a given case are determined. In the presence of a cause which can be removed by medical means operation is not indicated, and unless we find a cause the case cannot be treated logically. The little tinkering operations based on hypothetic conditions are certainly not indicated. If any operation at all is necessary it is an ileosigmoid anastomosis.

110. **Position of Stomach and Posture in Children.**—In eighty-three cases of general average developed children Sever found that the average position of the stomach is a much lower one than had been previously suspected, and that to find a stomach at or well below the crests of the ilium is not at all unusual. But one of these children had symptoms which were due to a dilated colon, which condition caused chronic constipation, and not to a stomach which showed a moderate ptosis. They were otherwise perfectly well as far as their digestive apparatus was concerned. The shape of the child's stomach as seen in this series was generally large and either horizontal or of the sink drain type. The ideal so-called cow-horn stomach was rare. Sever does not believe that posture in children, apart from the erect position of humans in general, has nearly as much to do with ptosis as has formerly been believed. What he believes has been shown proves that the child's stomach is lower than is generally supposed, and to find a stomach low in a child does not therefore mean that there is a pathologic ptosis. It is of course obvious that poor posture should be corrected and impaired general health built up, but he believes that neither is a cause of ptosis in children, nor that a low stomach is necessarily a weak link in the chain of a child's development.

136. **Treatment of Pelvic Thrombosis of Septic Origin.**—In 1911, two patients died in the Rotunda Hospital of pyemia, in one of whom, prior to death, a diagnosis was made of cellulitis in the region of the right utero-sacral ligament. In both of them at the post-mortem examination thrombosis was found in the ovarian veins. Jellett accordingly decided that, if there was another case presenting similar symptoms, and if there was any reason to think that thrombosis had occurred, he would interfere by operation and try to remove the affected vein or veins. Since then he has had to deal with four cases. In three of them an almost positive diagnosis of thrombosis was made before the operation, both from the physical signs and from the symptoms of the patient so strongly suggested the possibility of thrombosis that he opened the abdomen to explore. He found a hard, brawny swelling in the right broad ligament that could be traced to the infundibulo-pelvic ligament and along the course of the ovarian vessels upward beside the lumbar vertebrae. The tube was congested, but otherwise normal. He tied the uterine end of the broad ligament and incised the peritoneum over its face, and then with a little dissection was able to enucleate the mass in the broad ligament and to trace it upward along the course of the ovarian vessels, until he got up almost to the insertion of the vein into the vena cava. He tied the vein as high as possible and then removed the whole mass. The swelling in the broad ligament con-

sisted of the thrombosed branches of the ovarian vein, and the main trunk contained pus in its lower part, while its upper part was occupied by a thrombus that had not yet broken down. Three other similar cases are cited.

138. **Regeneration of Bone from Periosteum.**—On forty rabbits, two dogs and two cats, sixty-two observations were made by Haas. The experiments varied in duration from four to 249 days and extended over a period of two years. Under ether anesthesia the skin was shaved and painted with tincture of iodin. Incision was made through the skin over the selected ribs to the subcutaneous tissues. In case blood-clot was to be used in the experiment, the blood was collected in a sterile tube from the superficial vessels. Incision was next made through the muscles to expose the ribs, the latter being treated according to the demands of the experiment. The severed muscles were restored and the skin closed with silk sutures.

There are nineteen groups of experiments, in which the following methods are presented: 1. Simple subperiosteal resection. 2. Simple subperiosteal resection in which a small island of bone is allowed to remain in the periosteal gutter. 3. Simple subperiosteal resection of rib, remaining ends of which are covered with lead caps. 4. Elevation of rib from periosteal bed, from which it is separated by interposed muscle. 5. Same as 4, with addition of blood-clot in the periosteal gutter. 6. Extensive subperiosteal resection of rib, including costal cartilage, with addition of blood-clot to center of periosteal gutter. 7. Same as 6, excepting that the sternal side is blocked off with paraffin. 8. Same as 6, excepting that both sternal and vertebral sides are blocked off with paraffin. 9. Subperiosteal resection with paraffin at both ends, the interval between remaining empty. 10. Elevation of and removal of a section of the rib, the free ends being placed inside of a rubber tube.

Some of the deductions made by Haas are as follows: 1. The regeneration of bone may take place in two ways: (a) development of cartilage preceding formation of bone; (b) direct formation of bone. The experiments did not show whether the new bone arises from the periosteum or from the remaining bone stumps. 2. In three instances in which large bone pieces were left behind the amount of regeneration was very limited, and only in one case was the regeneration marked. 3. The periosteum alone did not regenerate bone. 4. The regeneration of bone occurred always from the point where the bone and periosteum diverged, and in general the amount of regeneration was directly proportional to the duration of the experiment. 5. There is marked increase of bone production in the presence of blood-clot. 6. It is possible that the new bone may have formed in the region of the blood-clot, and that subsequently it may have extended toward the costal cartilage, but this could not be definitely established. 7 and 8. Periosteum in the presence of blood-clot has the power of regenerating bone. 9. In the absence of blood-clot there was no evidence of regeneration of bone. 10. No evidence of new bone was found within the tube; on the contrary, there was definite evidence of necrosis of the enclosed bone. The most striking feature of the experiments is the influence of blood-clot in stimulating the formation of new bone. Another interesting feature of these experiments was the absence of the regeneration of bone from pre-existing bone which had been separated from its periosteum.

Haas summarizes his paper as follows:

> In cases in which the rib was isolated from its periosteal bed there was never any evidence of proliferation from the denuded bone. In fact, in the majority of cases the raised ribs became atrophic. In cases in which the severed ends of the denuded ribs were inserted between muscle fasciculi there was never any evidence of regeneration and where fractures were produced in the periosteum-free bone no evidence of union was found. These results are of considerable interest in view of the findings of Macewen, and further experiments are necessary to show whether the ribs differ from the long bones of the extremities in this respect. The constant occurrence of new bone at the angle of separation between the elevated rib and the periosteum raises the question of the relative importance of periosteum and bone in the regenerative process. If one assumes that the newly formed bone arises from the pre-existing bone, one would expect that the new bone should extend along the raised rib as well as in the periosteal gutter. The experiments do not show this to be the case. Although the new bone was always formed at the angle between the rib and the periosteum, it extended only along the periosteal gutter. It cannot be denied that the bone may have had some influence in originating the regenerative processes, but it is significant that the regeneration occurred only where periosteum was also present, and one cannot but conclude that the periosteum must have acted in some other way than by merely passively directing the distribution of new bone. It may be that the periosteum possesses some power, possibly of a chemotactic nature, which determines the direction in which the new bone shall grow, but from these experiments there seems little doubt that it also plays some important part in the actual regenerative process. In several experiments where the chondrocostal junction was removed it was noted that new bone was formed near the site of the junction. In practically all cases there was also regeneration of cartilage, and in some cases the new cartilage and the new bone were continuous. In the cases in which the new bone was separated from the cartilage it is difficult to explain its presence unless it arose from the periosteum. It is possible that the dependent position of this region when the animal is moving around may have caused the accumulation of blood-clot in this area, and that the combined action of the periosteum and blood-clot was responsible for the formation of the new bone.

139. **Gastro-Enterostomy.**—The authors hold that gastro-enterostomy, if properly done, is a drainage operation. After gastro-enterostomy, if the stoma is at the lowest part of the stomach in the erect position, the food leaves the stomach almost exclusively by the gastro-enterostomy opening. Under these conditions the stomach is emptied with great rapidity. They claim that gastro-enterostomy should be done only in the presence of pyloric stenosis, or pyloric spasm due to duodenal or gastric ulcer. The gastro-enterostomy opening should be made large and placed as close as is permissible to the pyloric antrum. In cases in which the gastro-enterostomy opening does not quite drain the stomach, the food leaves both by means of the stoma and the pylorus. Even in these cases, however, the stomach empties itself faster than normal. The authors believe that the clinical failures after gastro-enterostomy are probably due to the cases of faulty implantation of the stoma.

144. Abstracted in The Journal, January 11, p. 150.

148. **Influence of Thyroids on Pregnancy.**—Thompson experimented on pregnant bitches with the object of ascertaining the effect of disturbances of the thyroid apparatus during the height of sexual activity. In all, nine dogs were operated on. In five dogs one lobe of the thyroid was removed. In two one lobe was removed and the remaining thyroid tissue badly bruised and ligated and in one both lobes and some parathyroid were removed. In one both lobes were removed; and one lobe and the hypertrophied thyroid were removed from another dog and implanted in the site of the excised gland. Dogs in which one lobe of the thyroid was removed with no accidents gave birth to normal puppies and had abundant milk. The dog which had a severe hemorrhage during the operation, in the control of which there was sufficient injury to the remaining thyroid and parathyroids, equivalent to a ligation of the artery, had one puppy born dead and succumbed herself. One dog in which double thyroidectomy was performed together with the removal of some of the parathyroid tissue, had symptoms of tetany; gave birth to five living puppies, but appeared to have no milk, and the dog and puppies all died in a few days. The dog on which a transplantation was done escaped. The removal of one thyroid lobe has comparatively little influence on pregnant dogs or their pups after birth, but the removal of one-half, with injuries sufficient to destroy the function of the remaining thyroid and parathyroid tissues, is followed by tetanic seizures and death of mother and puppies. The total removal of the thyroids, with some parathyroid tissue, is followed by trembling, rigidity and after the birth of the puppies the milk was scanty, and later the mother and puppies succumbed.

Thompson concludes, therefore, that the thyroid gland, situated as it is in the neck, should have any sympathy with sexual functions if it was originally a gland concerned with digestion, is, to say the least of it, extremely unlikely; but on the contrary likely enough if it originated from a glandular organ in connection with the sexual structures of the paleostracean ancestors. There is clinical and experimental evidence of its connection with the sexual system of man and higher mammals through its secretion, in that a lack of thyroid secretion influences sexual activity adversely; that sexual activity, whether it be physiologic or pathologic, causes a hyperactivity of the thyroids, and that this hyperthyroidism constitutes an index to the toxemia of pregnancy to counteract which the thyroids raise their antitoxic protective power. There is abundant clinical evidence in support of the theory that what is termed a physiologic hyperactivity of the thyroid is a valuable safeguard against the toxemia of pregnancy.

150. **Gastrostomy Suggestion.**—When the catheter is introduced into the stomach in any method, McGuire passes it immediately through the pylorus into the duodenum. This procedure enables one to proceed with feeding at once, without fear of tension on the stomach sutures. The catheter is borne well by the duodenum, as McGuire has never seen any irritation due to it. In the course of three or four days the catheter is withdrawn into the stomach, the exact point of the catheter being previously marked. The advantages of this method in desperate cases are self-evident. It not only offers a safe method for the immediate introduction of food, but also insures a certain and definite means of introducing salt solution or tap water into the circulation. It offers the same advantages to gastrostomy operations that McArthur's procedure gives to surgery of the biliary passages.

153. **Anesthetometer.**—The anesthetometer devised by Connell is an apparatus for the automatic measuring and mixing of vapors and gases used to maintain anesthesia and for other purposes. The apparatus consists, first, of a gas meter as the measuring and motive mechanism; combined with, second, an ether reservoir from which volatile liquid is fed in accurately adjustable amounts; into, third, a vaporizing chamber; which is combined, fourth, with a trip-valve by which gases in any quantity may be mixed in accurate percentage. By the use of this apparatus, that accuracy of dosage in the administration of gaseous drugs so long deemed necessary for liquids and solids is secured. By the use of the anesthetometer, particularly in the intratracheal and intrapharyngeal delivery, the dosage of gaseous anesthetics becomes automatic, yet under the continuous observation and control of the operator. Thus efficiency and safety in prolonged anesthesia are secured, and the shock and sequelae of ether anesthesia are largely eliminated.

14. **Colon Infection of Urinary Tract.**—Pyelitis and cystitis, Marsh claims, are much more common in infancy and early childhood than is generally supposed. Mysterious febrile attacks, especially in females, should therefore not be attributed to dentition or gastro-intestinal indigestion until a careful examination of the urine for pus-cells and organisms has been made. The infection may be an ascending one owing to direct infection with feces through the urethra, or it may be a descending one owing to direct passage of the organisms from the bowel to the kidney; or lastly, and in rare cases, the infection may be carried by the blood-stream. The most satisfactory treatment is that by alkalies. The best drug for this purpose, Marsh finds, is the citrate of potash, which must be given in doses varying from 5 to 20 gr. every three or four hours. The urine generally becomes alkaline in one to three days, after which, as a rule, the temperature quickly falls, the symptoms subside, and the pus-cells and organisms rapidly diminish in number. If digestion is disturbed or diarrhea is set up by the citrate of potash, the alkalinity may be maintained by 5 to 10 gr. of bicarbonate of sodium or potassium given every two or three hours. Marsh has found citrate of soda added to the infant's bottle equally valuable under these circumstances. In cases which do not respond to this method, urinary antiseptics, after first rendering the urine acid, or autogenous vaccines should be tried. In spite of all treatment many cases became chronic; in these, acute exacerbations alternate with long periods of quiescence, but the urine never becomes entirely free from pus-cells and organisms.

16. **Appendicitis in Children.**—In view of the frequency—the increasing frequency and severity—of appendicitis in children, Simpson says, we should lose no opportunity of impressing on the public the possible severity of abdominal pain in a child. And he urges on the profession the advisability of early operation. Temporizing, waiting for an interval, or for more definite signs to develop, may be attended by most serious consequences. Early operation is the treatment of appendicitis in adults; it is even more important in children, in whom fewer cases remain localized to the appendix itself, in whom there is less tendency for adhesions to form, less chance of a localized abscess, and the disease runs a more rapid and severe course. In all stages of acute appendicitis in children operation should follow immediately on diagnosis; the signs and symptoms may be slight, with very serious conditions in the abdomen, and only surgeons with a very wide experience may, in rare cases, be justified in waiting for convalescence before performing their operation.

21. **Antemortem Thrombosis.**—If there is a danger of cardiac and pulmonary thrombosis, then stimulation, particularly of the heart, Fleming points out, would be the routine treatment for all cases in which such thrombosis *may* be *expected* to occur. Every case of croupous pneumonia should be treated early, and Fleming believes continuously, by the administration of a direct cardiac tonic, such as digitalis or strophanthus. Such diffusible stimulants as spirit of chloroform and aromatic spirit of ammonia should be given at once if the heart shows any signs of difficulty. Oxygen may counteract the excess of CO_2, which, according to Wiener and others, aids clotting. Fleming deems that it might be wise to depart from the usual plan of preventing any change of posture of the patient in bed. In fact, altering the position of the patient may be actually beneficial. The use of antithrombin ferment, he says, would be ideal, but at present it is not within the scope of practical therapeutics. Citric acid in 30- to 60-grain doses, four hourly, has been much commended in cases of venous thrombosis. If convinced that antemortem clotting is a cause of death in pneumonia, bleeding should never be performed unless in particularly robust patients, and never for what looks like engorgement of a dilated right heart. It may only aid thrombosis which has already begun. Auscultation of the pulmonary area should in any case be first carefully carried out.

22. **Duodenal Diverticula.**—The first of Wilkie's three cases is of interest in that a large duodenal diverticulum with an accessory pancreas in its wall occurred along with the curious condition of duplicature of the duodenal wall. In the other two cases—typical "diverticules perivateriens"—there was no evidence of pancreatic tissue in the walls of the diverticula, nor, on the other hand, was there any sign of distention or dilation of the duodenum. In two of these cases the presence in each of a *diverticulum in close anatomic contiguity with the* mon bile duct, together with the signs of stasis in that t, without there being any intrinsic obstruction of its en, offered strong presumptive evidence that there was some such etiologic relationship. It is possible that in both cases the stagnation of duodenal content in the diverticula led to a chronic catarrh of the duodenum, and that swelling of the papilla accounted in part for the biliary stasis which existed. Wilkie believes that diverticula of the second and third parts of the duodenum are of congenital origin. In the first part of the duodenum three types of diverticula are met with, the congenital, the ulcer diverticulum, and the acquired wide-mouthed diverticulum of the duodenal vestibule. Congenital duplicature of the duodenal wall may occur either along with or independently of diverticula; it is probably due to the persistence of a condition normally found at an early period of fetal life, and is, in fact, but a mild degree of that arrest of development which in its most pronounced form is met with in cases of congenital atresia of the duodenum.

23. **Rare Uterine New Growths.**—Haultain cites three cases: (1) simple papilloma of corpus uteri, (2) primary tubercle of cervix, (3) diffuse nodular fibrosis.

25. **Obstruction of Intestines.**—In Renton's last thirty-three cases of acute intestinal obstruction due to various causes there have been three deaths. There were five patients ill with intussusception and they all recovered. The important points which Renton urges should be remembered in connection with obstruction of the bowels, are: 1. Early diagnosis and early operation. 2. Where the obstruction is very acute, drainage by Paul's tube or other method. 3. The great importance of continuing drainage until the patient has sufficiently recovered to bear an operation, which may take three-quarters of an hour.

28. **Operation for Acute Appendicitis.**—Andrew maintains that drainage in cases of gangrene and of abscess is not necessary and often dangerous. Drainage can be dispensed with if the following two conditions are fulfilled: (a) removal of the cause, (b) thorough closure of the cecal opening. If these conditions are fulfilled, then Andrew says it is possible to obtain primary union where the very worst possible intra-abdominal conditions prevail, and with less risk than if drainage were adopted either by tube or by packing. Andrew analyzes his eighty-five cases so treated. In the greater proportion of the cases the appendix was gangrenous, either in whole or in part, and quite unprotected by adhesions from the general peritoneal cavity. In no less than one-third of the cases the appendix had perforated, and a coprolith was either lying free in the general peritoneal cavity or in process of extrusion. The accompanying peritonitis was either local or general; it was quite impossible in some of the cases to be certain how far the infection had spread. Though not stated in the summary of the cases, if any doubt existed as to the involvement of the pelvic peritoneum a small suprapubic incision was made, and the pouch of Douglas mopped out. In a smaller proportion of the cases a localized abscess was present, completely shut off and usually very foul-smelling. In almost every case the offending appendix was removed, and every care taken to effectively close the cecal attachment. Iodoform powder was dusted over the stump in the earlier cases; iodin or iodoform emulsion, either alone or combined with the subcutaneous injection of a bacillus coli vaccine, in the later cases.

In eighty out of the eighty-five cases the wound was primarily closed without drainage. The cases drained were those in which the appendix could not be found or those in which the stump could not be effectively closed. The subsequent introduction of an intra-abdominal drain at the seat of the appendix was necessary in only two cases, and in these Andrew was in doubt as to the satisfactory closure of the stump. Fifty-seven out of the eighty-five cases healed primarily. In twenty-seven there was some infection of the wound; in two the wound was restitched. In no case was a drainage tube necessary for the wound alone. In three of the patients who died the wound had healed or was in process of healing without sepsis, and that with a pronounced peritonitis in progress. There were seven deaths. In one case death occurred six hours after admission; this case was drained. In every case save one death was due to general peritonitis, either in existence at the time of the operation or becoming general subsequent to operation.

39 Sterilized Pus for Treatment of Infections and Sterilized Cancer Inoculations. V. B. Nesfield.
40 Case of Serum Therapeutics. M. Ram.

38. **Residual Eruption in Small-Pox.**—On April 28, Fink's patient, a male, aged 22, was for an hour in the house of a person in the scaling stage of the disease. On May 20, he had a temperature of 104.6 F. He was kept under observation the next day, and on May 22, he was admitted and segregated, as eruptions appeared on his face, forearms and body. He stated that he had had fever, backache and pains in his joints from May 18, but had not reported feeling ill. He had two fair-sized vaccination scars on his left arm; said to have been vaccinated fourteen years previously, when he was 8 years old. He had not had small-pox before and had never been inoculated. He had also not been revaccinated till four days after his admission, but this was not successful. He was then

in the incubation stage of small-pox. Eruptions first appeared on the night of May 21, but these were not seen till the following morning and the question of diagnosis, small-pox or chicken-pox had to be decided. As twenty-one days appeared to be a very long incubation period for small-pox, the further development of the eruptions was carefully watched.

The following are the principal points noted: The vesicles developed slowly as in small-pox and scabs began to form on the face first on the tenth day. The majority of the vesicles were globular, but some were irregular in shape. They were closer set on the face than on the body; closer on the forearms than on the arms; closer on the legs than on the thighs; closer on the back than on the front of the body; closer on the upper than on the lower part of the back; they were more numerous on the extensor than on the flexor surface of the extremities; they were well-developed on the hands and feet and formed well-marked "seeds" in the palms and soles. The majority of the vesicles showed no umbilication and appeared superficial. On pricking some collapsed and others did not. Secondary fever occurred when the stage of pustulation began. The slow development of the eruptions, their appearance first on face and forearms, their density in the areas above-mentioned, secondary fever, and the presence of "seeds" in the palms and soles left no doubt as to the disease being small-pox.

On September 21, two and a half months after he was convalescent, he had an attack of fever, but the temperature was not recorded. The following morning papules appeared and some of these developed into vesicles. A few of these vesicles became pustular and scabs formed. The lesions were in every respect similar to those of a mild case of chicken-pox or modified small-pox. The patient had not been in contact with any person suffering from either of these diseases. The eruptions were most numerous on the back and chest, and there were a few on the face and extremities. They were all very superficial and the scabs were thin. On examining the hands two "seeds" were found on the palmar aspect of the left hand, and one, resembling the "dark, black area" described by Cameron and really a vesicular "seed," on the right middle finger. Shortly after the eruptions appeared, the glands in the axillae and in the femoral region were swollen to the size of a pigeon's egg. The scabs had all fallen off by October 4, and the patient was practically well. No secondary fever occurred with the residual eruptions..

61 Acute Abdomen on Board Ship. G. Shaw.
62 Tabes with Unusual Distribution of Deep-Pain Loss. T. A. Williams.
63 Case of Rat-Bite Disease. F. Nicholson.

51. **Gynecologic Emergencies.**—Maxwell's paper is limited to the consideration of three affections, which all have this one factor in common—the sudden supervention of acute abdominal symptoms in a woman of apparently normal health. These are: (1) ectopic gestation in its numerous forms; (2) twisting, and the secondary changes dependent thereon, of ovarian cysts. In the first, the difficulty of diagnosis, at least in acute rupture of the tube, is much less than in the other two; (3) "ascending inflammations" of the pelvic peritoneum, to which the female abdomen is specially predisposed by virtue of the open celomic ostium.

52. **Pelvic Disorders and Neurasthenia.**—In 98 prolapse cases operated on by Oldfield prior to March, 1911, and investigated after October, 1911, there were 2 complete recurrences, 3 partial, 3 with symptoms unexplained by physical signs, and no case of neurasthenia; 143 fibroids with 3 patients who had neurasthenic symptoms; 2 of them soon recovered, and the other was a confirmed neurasthenic, and now has mental symptoms; 15 other patients had some symptoms, of whom 2 had renal calculus, 1 had hydronephrosis, 2 developed acute appendicitis, and 2 had gonorrhea. With appropriate treatment, all these patients have done well with the exception of one with renal calculus, who still has some renal pain with pyuria. In 104 major operations in connection with pregnancy, consisting of extra-uterine gestation, classical and vaginal cesarean sec-extra-uterine gestation, classical and vaginal cesarean sections, tumors with pregnancy, acute appendix and gall-bladder lesions, only one neurasthenic case was found, and it appears that domestic unhappiness accounts for this case. Since reporting these results Oldfield has performed nearly 200 more prolapse operations and forty-five more hysterectomies for fibroid tumor; although these cases have not been followed up, as far as one knows not a single patient has neurasthenia. There were five deaths in 345 operations reported in the three papers referred to, and in the subsequent 240 cases not a single death occurred. Oldfield holds that pelvic disorders have no specific action in causing neurasthenia. Pelvic complaints, with the exception of disorders of menstruation, are as often as not unassociated with physical signs, and due to a general neurasthenia. Certain conditions, such as slight exposure of vaginal wall, cervical erosion, laceration, retroflexion of uterus, prolapsed ovary, ovaritis and cystic ovary, do not produce symptoms, and do not require treatment. Chronic pelvic inflammation, calling for operative treatment, sometimes exists apart from recognizable tumor formation. Greater care is necessary before, during and especially after, operation, in order to prevent postoperative neurasthenia. Before operating on neurasthenics with gross disease, and before operating on patients without demonstrable physical signs, Oldfield says, the surgeon should seek the advice of the physician.

65 The Phenolsulphonephthalein Test of Renal Function. G. Mouriquand.
66 *Atrophy of the Uterus as Result of Lactation. (Maladie de Basedow et maladie de Frommel.) Maurice.

66. **Atrophy of the Uterus as Result of Lactation.**—Frommel in 1882 published an article in which he said that as a result of lactation the uterus frequently undergoes such an extreme degree of involution that it cannot afterward be restored to normal size. He recommended that the genital organs be examined frequently during lactation and if excessive decrease in size of the uterus be observed that nursing be stopped. Maurice reports a case of excessive secretion of milk in a young woman while nursing her first baby. It was followed by uterine atrophy, so that she never had another pregnancy. During lactation swelling of the thyroid and marked symptoms of hyperthyroidism had been noted. It is known that utero-ovarian atrophy frequently occurs in association with

exophthalmic goiter, and Maurice concludes that there is a physiologic antagonism between certain glands which stimulate the cortex and vagus (such as the ovaries and pancreas), and others which excite the sympathetic system (such as the thyroid and mammary gland). Hence nervous women who show that their sympathetic nervous system is especially sensitive should be supervised with particular care during the nursing period.

69 Relation between Appendicitis and Diverticulitis. M. Guibé.

68. **Nodose Erythema.**—Aubert warns that this variety of multiform erythema calls for a diagnostic tuberculin test as *it is so often a manifestation of the earliest phase of infection* with the tubercle bacilli. It is far wiser and safer to let the family know at once that the trouble is constitutional and not a mere transient skin disease. Telling the family that the trouble is a bacillosis sounds the alarm and gains consent to appropriate measures. Otherwise treatment is restricted to local applications or less. He reports four cases to show the necessity and extreme advantage of treatment on the basis of this conception of "pretuberculosis." He adds that the text-books should cease to class erythema nodosum as a separate morbid entity.

74 *Hematuria Caused by Urotropin given in Typhoid Fever. (L'hématurie au cours de la fièvre typhoide traité par l'urotropine.) J. Belkowski.

74. **Hematuria Caused by Hexamethylenamin.**—Hematuria from this cause is a comparatively rare occurrence. In 1906 Karkowski could find only five cases in the literature. Crowe in 1912 reported seven cases among ninety-five patients treated. Belkowski has encountered four cases and reports in detail one which occurred in a fatal case of typhoid. The changes found at necropsy were confined to the bladder, the *kidneys not being affected. Hematuria is more apt to occur in cases* with very high temperature, as this favors the decomposition of the hexamethylenamin into formaldehyd and ammonia. These four cases occurred among forty typhoid patients who were given doses of 0.5 or 0.6 gm. three to four times a day. *The hematuria did not seem in any case to influence* the typhoid unfavorably and it stopped when the hexamethylenamin (urotropin) was discontinued.

79 Heating the Ether for General Anesthesia. (La narcose à l'éther chauffé.) C. Julliard.

75. **Emotions, Psychanalysis and Psychotherapy.**—Dubois here describes his conception of the causes of psychopathies, the *théorie intellectualiste* which for years he has been teaching. He reiterates that every sentiment is an emotion; every sentiment generates at once a tendency to motion, toward or away from, and this reaction of attraction or repulsion is the primary phenomenon of life—the instinct of self-preservation. Whether the individual is conscious of it or not, the process is always the same. There is first perception of the stimulus, then the brain passes logical judgment *on the stimulus and it is only after the stimulus has been thus weighed and judged that the emotion follows*, bringing with it the action. Dubois insists that logic is a single and absolute rule which every one obeys, everyone without exception. The mind works like an adding machine that always gives the same sum, given the same figures to add. This logic of the human *mind is impeccable* in old and young, great and small, unless the brain is profoundly diseased. But the premises on which the logical conclusion is based differ for all, and these premises are the result of multitudes of conscious and rudimentary ideas inherited or imprinted by education. The premises depend on our capacity for estimating things in their true proportions. The inability to estimate events at their true value entails a morbid judgment, and this is the cause of the exaggerated emotivity of psychopathic patients. Rational educative psychotherapy and prophylaxis aim to train them to formulate their premises more correctly; with correct premises comes sound judgment.

The psychopath regards minor happenings and reacts to them as the normal regard and react only to serious tragic events. The emotional crisis is an actual orgasm which sets a whole series of organic apparatus at work; this activity *entails fatigue*—and emotional fatigue, Dubois adds, is about the most pernicious. The fatigue brings with it a number of disagreeable sensations which fix anew the worried attention of the patient. The physiologic disturbances caused by the psychopathic exaggerated reaction, gastro-intestinal disorders, tachycardia, neuralgia, headache or the like, add a new source of emotions to the original one, and the original phobia is followed by phobophobia. There is besides this the physiologic law that repetition occurs more easily each time. It is not necessary to dig into the past for a sexual trauma, as Freud does; *the obvious cause will generally suffice* for effectual psychotherapy, convincing the patient that his premises are erroneous. Then the whole structure of his phobia falls to pieces and he is cured. A frequent phobia Dubois has encountered is the dread of microbes; most of these patients have never seen microbes *under the microscope and have no idea of* their actual size. One of his patients had a phobia that his tailor had sewed tubercle bacilli in with the silk in making buttonholes. The simple dread of contagion or an exaggerated idea of the toxicity of certain poisons *explains many such cases without search for an erotic factor.*

The psychasthenic imagine absurd things and they sometimes know this. Treatment aims to prove to them that it is their emotional state which impairs their logic. This tranquilizes them *as they realize that they* will estimate things at their true value better when their emotion has quieted down. He gives a number of concrete examples to illustrate these views.

80 *Duodenal Ulcer in Children. L. Cheinisse.

80. **Duodenal Ulcer in Children.**—Bichat and Imfeld have reported a successful operative case of duodenal ulcer in a girl of 14 and a boy of 15, and Cheinisse states that duodenal ulcers have been found at necropsy of very young *children*, even infants. Helmholz and Schmidt have reported *finding* evidences of healed ulcers at necropsy of children who had died from other causes. In Schmidt's case the child was only five weeks old. In Bichat's case an interval of twenty-four hours had elapsed between the perforation of the duodenal ulcer and the operation and yet the child recovered.

87 By-Effects of Salvarsan. (Ueber Salvarsanstörungen.) W. Gennerich.

81. **Treatment of Syphilis.**—Bering insists that every physician who has anything to do with *the treatment of syphilis* should familiarize himself with the technic for detecting the spirochetes so that he can seek for them at once without waiting for symptoms to develop. Another point on which he lays great stress is that local treatment of primary lesions and skin and mucous membrane lesions should never be omitted; they should be cut out when possible. If excision is not practicable, he injects a 1 per cent. solution of mercuric chlorid, applies the thermocautery and dusts afterward for a long time with calomel. Otherwise the spirochetes are liable to lurk for years in or around these lesions. In one of his cases a woman was *infected by her husband ten* years after his primary chancre. The Wassermann reaction is more likely to be positive when the syphilitic manifestations are numerous and extensive; with monosymptomatic syphilis it was positive only in 37 per cent. of his cases. He is convinced that even reinfection is no guarantee that all the spirochetes from the primary infection have been exterminated.

The cerebrospinal fluid findings in 285 cases are listed to illustrate the remarkable frequency of changes in the fluid in all stages of syphilis, even the very earliest, possibly while the blood-Wassermann is still negative. Besides its diagnostic value, lumbar puncture often has a decided therapeutic influence on headache and other signs of abnormal pressure on the brain. He regards salvarsan as superior to mercury in the primary stage, but three or four repetitions of a dose of 0.3 or 0.4 gm. are necessary. He warns against ever going above *this dose; in later stages he prefers 0.1 or 0.2 gm., repeated* eight or ten times. The older the syphilis the less effectual is salvarsan, and mercury is superior to it in the secondary and third stages; he combines the two but pushes the mercury. Inadequate treatment does actual harm, merely rousing the spirochetes without exterminating them. The discovery of the spirochete is by far the greatest progress realized in the matter of syphilis to date, he declares. This enables us to differentiate the disease when it has just got a foothold and root it out at once.

83. **Electric Treatment of Obesity.**—Carulla reports a case in which he applied Bergonié's method and reduced the weight of the patient, a man of 40, from 174 to 108 kilograms, a reduction of over 145 pounds. The method is based on the muscular contraction that follows an electric discharge, and Bergonié has evolved a technic which permits such extensive and repeated contractions of different groups of muscles that the muscles get a maximum of exercise with the minimum of fatigue, thus providing ideal conditions for correcting the tendency to obesity. He uses the secondary current from an induction coil with a tension of 8 or 10 volts, the current interrupted by a metronome with a beat of 120 to the minute. *This current is brought to the body through electrodes* which cover large parts of the body. They are kept moist, and are held in contact with the body by means of bags of sand. The current of 40 up to 100 milliamperes is applied at first for fifteen or twenty minutes once or twice a day and later for fifty or sixty minutes each time. After four or six weeks the treatment is suspended for six months and then the course is repeated. During the interval the patient generally loses 20 or 30 pounds, and during the second course loses still more, so that the weight is usually reduced on the whole from 60 to 88 pounds and the tendency to obesity seems to be permanently conquered; of course the electric treatment has to be aided by rational dieting. Carulla's patient had an electric apparatus installed in his home for the purpose. The galvano-faradic current was applied through two large metal electrodes covering most of the abdomen and held in place with elastic bands. The galvanic current was reduced after a time and the faradic increased and varied during the nine months of the courses and intervals. There has been no tendency to an increase in weight *during the three months* since the close of the courses although the patient does not restrict his diet.

84. **Thrombosis in Measles.**—Lutz states that in eight of a recent series of twenty-two fatal cases of measles extensive *thrombosis* was found at necropsy; the pulmonary arteries were particularly involved in six and in two also the cerebral arteries. In five cases the veins or right ventricle was also involved, in one the portal and mesenteric and in one the portal vein and sinuses in the brain. He has been able to find only eleven other cases on record of thrombosis in measles.

86. **Splenectomy in Pernicious Anemia and Other Blood Diseases.**—Eppinger concludes from his experience with splenectomy in ten cases that it is liable to have a curative action whenever there is destruction of the blood from any cause. Not only *in hemolytic jaundice but also in pernicious anemia,* benefit may be derived from splenectomy. He performed the operation in two cases of hemolytic jaundice; in two of pernicious anemia; in three of Banti's disease; in two of cirrhosis of the liver and in one of severe catarrhal jaundice threatening transition into acute yellow atrophy of the liver. The result in the hemolytic jaundice and pernicious anemia cases was surprisingly good; the urobilin in the stool dropped from 3.95 before to 0.62 a week later in one of the former cases and from 0.65 to mere traces in one of the pernicious anemia cases, while the reds increased from 1,160,000 to 4,900,000 *in six weeks and the weight by 8.8 pounds. The spleen* was not enlarged in either of the pernicious anemia cases. During the five and six months since the men have continued to gain in weight and feel perfectly well.

Eppinger's experimental research throws further light on the hemolytic properties of the spleen and his experience confirms the importance of the urobilin content of the stools as an index of the destruction of red corpuscles going on. The findings in some cases of valvular disease and cardiac insufficiency indicate that destruction of red corpuscles is an important factor in the syndrome presented here, as also in the syndrome of cirrhosis of the liver. Congestion and stasis of the blood favor destruction of the reds, and this is particularly evident with cirrhosis of the liver. The accompanying enlargement of the spleen incriminates the latter as the organ mainly involved in the hemolysis, and the improvement in his cases after splenectomy confirms this. Most of the patients in this liver *group had been sent* to the hospital with the diagnosis of gall-stone colic but the biliary passages were found normal. Congestion in the liver or spleen or both was probably responsible for the paroxysms of pain in these cases. Eppinger adds a warning that with an apparently harmless catarrhal jaundice connected with some gastro-intestinal intoxication, the spleen may become enlarged and the temperature may rise, but contrary to ordinary catarrhal jaundice, the stools are not clay-colored. There are large proportions of urobilin and urobilinogen in the urine, and the patients are liable to succumb suddenly with symptoms of acute yellow atrophy. He has recently lost two patients under these *circumstances.* In a more recent case the trouble had lasted for two months with headache and vomiting along with the jaundice. Two days after splenectomy the urine was free from urobilin, the jaundice promptly subsided, and the patient seemed restored to complete health. (See abstract 161 below.)

96 *Minimum Albumin Requirement. (Studien über Eiweissminimum.) M. Hindhede.

96. **Minimum Requirement of Albumin.**—Hindhede has been experimenting for seventeen years with a diet poor in nitrogen. He lived for a month on a diet of new potatoes, butter and strawberries. His children have grown up on a diet low in albumin, and are in the best of condition physically and mentally. He gives tables showing in detail the results of his experiments. Both he and a laboratory assistant lived for long periods on potatoes and oleomargarin, with a daily nitrogen excretion of 5 gm. He found that a nitrogen balance could be maintained on 20 gm. of digestible albumin to 3,000 calories. He agrees with Chittenden's well known low estimate as to the nitrogen requirement. He mentions Kumagawa's conclusion that the lower classes in Japan who live chiefly on rice are stronger than the upper classes who eat meat.

113 *Essential Fragility of the Bones. (Zur Pathologie der idiopathischen Osteopsathyrose.) D. G. Zesas.
114 *Rational Pneumopexy in Surgery of the Thorax. G. Lerda.

107. **Injury of the Crucial Ligaments in the Knee-Joint.**—Goetjes adds seven cases to the twenty-three he has found on record and devotes sixty-nine pages to discussion of the conditions and operative repair when the crucial ligaments are ruptured or crushed. He refers to Robson's work in this line mentioned in The Journal, 1903, xl, p. 1539.

113. **Essential Fragility of the Bones.**—Zesas reports a case of idiopathic osteopsathyrosis in a woman of 57, constantly healthy until the last four years, when she noticed that her arms were weak and tired very easily. The shoulder and arm muscles were atrophied and one humerus and both ulnas showed signs of old fracture. The patient had no knowledge of the fractures but remembered a period two years before when she had had supposed rheumatic pains in her forearms. She died suddenly with symptoms of cerebral hemorrhage, but there was no necropsy.

114. **Rational Pneumopexy in Surgery of the Thorax.**—Lerda gives an illustrated description of the technic with which the lung is fastened to a broad opening in the skin and thus held artificially expanded. All agree that the lung bears suturing remarkably well, and the pneumopexy prevents threatening collapse and shriveling. The incision he recommends for the purpose is along the base of the pleural cavity, cutting but not resecting the ribs. The incision is carried from the sixth interspace, outside the nipple line, to the ninth interspace. The wall of the chest then gapes and affords ample access to the lung, diaphragm and mediastinum. He has had no clinical experience as yet with this technic.

121 Increase of Trabeculae in the Spleen in Rachitis. (Ueber das Verhalten der Gitterfasern in der Rachitismilz.) A. Hayaski.

118. **Effect of Carbohydrate Excess in the Diet.**—Children fed on infant foods containing an excess of carbohydrates may seem well nourished and gain in weight for a long time. Finally, however, there is a loss in weight extending sometimes to extreme atrophy but masked frequently in the terminal stages by edema. Frank and Stolte believe that the harm is due not so much to the excess of carbohydrate as to the lack of other elements found in the normal food of the infant. Nitrogen and mineral salts are found in much greater quantity in milk than in the oat or wheat flours that form the basis of so many infant foods. Tables are given showing the percentages. Lipoids and fat are also lacking, but the fat deficit can be made up to some extent from the carbohydrate. The bodies of infants so fed contain more water than normal, and they are more susceptible to infection. Analyses of the livers from four cases are given, supporting these conclusions.

119. **Raynaud's Disease and Inherited Syphilis.**—Bosanyi describes two cases of congenital syphilis in which Raynaud's disease was present. It disappeared simultaneously with the symptoms of syphilis under luetic treatment, and in one case returned later with a recurrence of the manifestations of the syphilis. He cites similar cases from the literature and draws the conclusion that Raynaud's disease may safely be regarded as one of the manifestations of hereditary syphilis.

122. **Chronic Peptic Ulcer Near the Pylorus.**—A similar article by Faber was summarized in The Journal, 1913, lx, p. 638. He here brings the history of some of his cases down to date, and emphasizes anew the diagnostic importance of intermittent stenosis of the pylorus. Spasmodic closure of the pylorus, with intervals of complete freedom from stenosis, is a sign of ulcer close to the pylorus, whether on the stomach or duodenum side or encroaching on both. According to his experience the hunger pains coming on not until two hours after eating are not pathognomonic for duodenal or gastric ulcer but may occur with various intestinal affections. He warns not to suggest by one's questions the character of the pains felt by the patient, and he insists on the necessity for objective findings before accepting a peptic ulcer. There must be evidence of gastric hypersecretion, especially 200 c.c. or more of acid stomach content after an Ewald test-breakfast, delay in evacuation of the stomach after the Bourget-Faber retention test-meal, and blood in stomach or stools, visible or occult. With a juxtapyloric peptic ulcer, operative treatment is necessary if a tendency to spasm of the pylorus persists, even in a mild form, after a thorough course of internal treatment of the ulcer. He found that in over 50 per cent. of all his chronic ulcer cases the ulcer was close to the pylorus, and that all disturbances vanished at one stroke after a gastro-enterostomy. The attacks of spasm of the pylorus may be so mild that they do not attract the patient's attention, but certainty can be obtained by the stomach-tube showing much retention at one time and little, if any, at others.

123. **Etiology of Arteriosclerosis.**—The main point which Herz emphasizes is the importance of grief and worry in the origin of arteriosclerosis, and the necessity for the physician's being a true friend of the family and adviser in order to better conditions in this respect. Far too little attention is paid as a rule to the nervous or psychic factors contributing to arteriosclerosis. Physicians are liable to scoff at the idea that one can die of a broken heart, but humanity at large and many general practitioners know that this does occur. Herz has recently had a case of the kind in his practice: A woman whom he knew to be perfectly healthy was actually consumed by grief and died of coronary sclerosis when her daughter went wrong. Women die from grief; men from worry over business. The effect of emotions on the vascular system is most serious when the vessels involved are connected with the brain, heart or kidneys. The physician who does not apply psychotherapy in treatment of arteriosclerosis neglects one of the most effectual means at his command. With cerebral-neurasthenic arteriosclerosis, iodin is the main reliance; with coronary trouble, theobromin and nitrites; but all these are of little if any use when the arteriosclerosis affects the cardiorenal vessels. Dieting is the reliance here.

Herz adds that even if alcohol and tobacco may be factors in the vascular trouble, yet any benefit from dropping them entirely is far outbalanced by the patient's longing for his accustomed stimulant. Everything should be done to make the patient placid, comfortable and cheery. An alcohol rub in the morning before rising is an important aid. If he dreads balneotherapy, do not insist on it or on anything that will annoy or distress him. Herz declares in conclusion that prophylaxis of arteriosclerosis should begin in childhood. Children are generally driven as being naturally lazy and ambitionless, but he insists that this is a mistake. Most people, even children, try to do too much; they work and worry too much. Children should be trained to recognize that they owe a duty to themselves, to seek fun as a recompense for fulfilling their ordinary duties. Joy does not come to us as sorrow does; we have to seek for it, and few understand this. We physicians, for example, are far too much slaves to duty, we overwork and ruin ourselves. (. . . *viel zu sehr Pflichtmenschen, wir überarbeiten und ruiniren uns.*)

126. **Differentiation of Organic and Functional High Blood-Pressure.**—Deussing eliminates all the functional factors possible by taking the blood-pressure in the morning before the patient gets up and while he is still fasting. This not only excludes psychic and physical factors, but it also excludes any possible mechanical influencing of the heart by the full stomach. Organically high blood-pressure is the same under these conditions as ot other times, but a previously functional high blood-pressure will be found practically normal.

134. **Expectant Treatment of Eclampsia.** — Lichtenstein believes that the expectant treatment by bloodletting and narcotics is to be preferred to operative interference in eclampsia. He gives his statistics for ninety-four cases, with the histories in twenty-four of the most severe cases. He had five deaths, a mortality of 5.3 per cent. None of the deaths could be attributed to the form of treatment. The infant mortality was 37.3 per cent. as against 38.8 per cent. for active treatment in previous years. Psychoses occurred in 2.1 per cent. as against 6.75 per cent. for the active treatment. In 54 per cent. of the cases the attacks ceased after a single venesection; 42 per cent. of the women with antepartum attacks recovered before labor came on. Seventy-four successive cases were treated without a death. Naturally, with either method of treatment, the results are the more favorable the earlier it is begun. He recommends the lateral position, as respiration is freer and there is less pressure on the abdominal vessels and ureters than in the dorsal position.

135. **Laparotomy for Interruption of Pregnancy and Sterilization.**—In cases in which it is necessary to interrupt pregnancy and sterilization is indicated, Sellheim opens the abdomen, incises the uterine wall, empties the uterus, closes the uterine wound and excises the tubes. He has operated in ten cases in this way and believes it is more favorable to the patient than emptying the uterus by the vaginal route and performing a salpingectomy afterward, as the latter method involves two anesthetizations.

148 *Bronchotetany, Asthma and Asthmatic Bronchitis in Infancy. H. Rietschel.

140. **Development of Artificially Fed Infants.**—Phillippson gives the weight curves of twenty-three infants fed artificially for periods of more than two weeks during 1912. With the exception of two who have died, all the children made satis-

factory gains in weight and none suffered from severe rickets. As compared with breast-fed infants, however, the curves do not show as great gains. They were fed on a simple dilution of sweetened cow's milk. In some cases beet sugar was used and in others Soxhlet's sugar with no appreciable difference in results. Phillippson prefers this simple nourishment to albumin-milk, malt, buttermilk, or any of the more complicated formulas frequently used.

142. **Dosage of Calcium Salts in Spasmophilia.**—Blühdorn here brings down to date the report of his experiences with calcium chlorid, previously summarized in The Journal, July 19, 1913, p. 228. He has applied this treatment now in twenty-six cases. The little patients were all between 4 and 12 months old except one of 2 years and one of 4½. The last mentioned child had repeated attacks of spasm of the glottis and they did not return after ten tablespoonfuls of the 10 per cent. solution had been taken within twenty-four hours. The dosage advocated was decided on after study of the effect of tentative dosage on the electric irritability of the median nerve tested between 9 and 10 a. m. and 6 and 7 p. m. He reiterates that large doses are necessary the first day, 2 or 3 gm. of the chlorid or bromid at a dose, up to 4 or 8 gm. in the course of twenty-four hours. This will stop convulsions and other symptoms of the spasmophilia but does not have much effect on the electric excitability of the muscles. The same dosage, he states, should be given where calcium salts are used in other diseases, such as constitutional eczema, asthma or tendency to hemorrhage. The effect is soon manifest with this dosage but it disappears quickly. It is really a symptomatic improvement which ceases as soon as the medication is discontinued. No change in diet need be made. The comparative efficacy of the various salts depends partly on their calcium content and partly on the ease with which they are absorbed.

143. **Pulmonary Tuberculosis in Infants.**—Lederer describes five fatal cases of pulmonary tuberculosis in infants and three in which the children recovered. In all the fatal cases there was miliary tuberculosis of various internal organs. He believes that the infection was of air-borne origin, the primary focus being in the lung with involvement of neighboring lymph-nodes. The prognosis in early infancy is extremely unfavorable, but he gives the three cases of recovery to show that it is not hopeless. The difference in the outcome is due partly to the severity of the infection, partly to the environment of the child as to light, air, food, etc., and partly to predisposition, as he believes that there is such a thing as congenital tuberculosis.

145. **Calcium Lactate in Digestive Disorders of Infancy.**—Aschenheim is convinced that the use of the so-called albumin-milk is a tremendous advance in infant feeding. It is, however, difficult to make and expensive, and he has been looking for a cheaper substitute. In many cases of mild or moderate dyspepsia he has found calcium lactate answer much the same purpose. He feeds a mixture of milk and water or milk and oatmeal and water, enriched on the second day with a little cream. In severe cases no sugar is used; in milder cases Soxhlet's sugar. In addition he gives from 7 to 10 gm. calcium lactate per day, that is, 70 to 100 c.c. of a 10 per cent. solution. He regards calcium lactate as a valuable aid in the management of dyspeptic conditions in infants, basing his conclusions on its results in sixty-one cases.

146. **Surgical Scarlet Fever.**—Hahn gives histories of seventeen cases of scarlet fever occurring in his surgical clinic after wounds or operations. The most of them followed burns or operations for empyema. The eruption began in most cases around the wound and the typical picture of scarlet fever then developed. It was, however, milder than ordinary scarlet fever. In only one case was there any ear affection or swelling of the lymph-nodes. There was no nephritis or heart affection in any case. He attributes this to the fact that the infection was probably with an attenuated virus.

148. **Bronchotetany.**—Lederer described in the *Ztschr. f. Kinderhlk.*, 1913, vii, 1 (abstract in The Journal, 1913, lx, 1931), a condition which he called bronchotetany. The most characteristic feature of it is the extreme dyspnea caused by spasm of the bronchial musculature, preventing the access of air. He gave the differential diagnosis from pneumonia and asthma and described six cases.

Rietschel here reports a case of almost a month's duration, ending in recovery. He thinks the differential diagnosis from true asthma is more difficult than would appear from Lederer's article, and emphasizes the importance of making the distinction, as the treatment for spasmophilia is of a different nature and far more hopeful than that for true asthma.

149. **Pancreas Secretion Dependent on Stomach Secretion.**—The experiments were made on a large dog whose gall-bladder had been connected with the small intestine after severing the common bile duct. A tube was worn in the duodenum through which gastric juice was injected. Injection of a small amount of normal or hyperacid gastric juice was followed by profuse secretion of pancreatic juice. On the other hand, injection of the stomach secretion from patients with gastric cancer or simple achylia was followed by little if any secretion in the pancreas. The latter is evidently the result of several factors. When the most important factor—the chemical stimulus from the hydrochloric acid—drops out, the inadequacy of the remaining factors is liable to lead soon to severe impairment of pancreas functioning.

151. **Vital Staining of Spirochetes.**—Meirowsky describes the stain with which he has been able to color living spirochetes without apparently impairing their vitality. He was surprised to find with this technic that the *Spirocheta pallida* sprouts one or more buds and that new spirochetes spring from these buds. The buds can be seen dividing like the nucleus of a true cell into two, four or more parts, and the young spirochetes develop from these fragments, regardless of whether the buds are still connected with the body of the mother spirochete or whether they have been detached from it. If further research shows that the spirochete belongs to the protozoa, the propagation is here of an asexual type. There is of course a possibility that the spirochete may prove to be a plant structure which proliferates by production of spores. The budding has interesting features as he shows with an illustration of over seventy-four different types. The vital staining seems to be possible with any methyl violet. The budding is visible also in the ultramicroscope and with the spirochetes of balanitis and stomatitis.

153. **Lymphosarcoma.**—Fabian presents evidence from his own experience and from the literature that a lymphosarcoma limited to its site and the regional lymph-nodes may sometimes be cured by a radical operation. Occasionally an inoperable or generalized lymphosarcoma may become arrested and even retrogress, passing into a latent stage, but to date no instance is known of an actual complete cure. These retrogressions have followed an intercurrent infectious disease, partial operations, radiotherapy or injection of Coley's fluid; they

have thus been observed after the most varied measures or without any medical measures. Fabian reports two cases: In the first an inoperable lymphosarcoma of the jaw and cheek retrogressed under arsenic and the Roentgen rays, and examination thirteen months after the course of treatment showed that the retrogression then realized had been permanent, nothing being left of the growth, only extreme atrophy of the tissues in its place. The patient, a woman of 56, had gained 10 pounds in weight. In the second case a robust man of 65 had the lymphosarcoma develop on the nose in a few weeks. The growth was excised and there has been no sign of recurrence during the two years and three months since, although the depths of the tumor had not been reached. Such cases teach the necessity for prompt and energetic treatment as giving some hope, although the prognosis should always be extremely guarded.

156. **Psychology of the Testimony of Persons Injured in Accidents.**—Foerster declares that the testimony of persons who have passed through an accident is liable to be incorrect and misleading even at the best. At the moment of the injury, and on account of the injury their perception of what is going on may be impaired. What was noticed may be forgotten later, while the gaps in the memory are filled up by vague memories of what occurred, by reasoning backward from the injuries observed, by unconscious assimilation of the descriptions of other persons, and by analogous experiences in other circumstances. In the elderly and those with clouded minds, the actual occurrences may be incorrectly interpreted. The fright alters the conception of time: when there is pain, the interval seems longer; or the fright may obliterate the interval between the events.

163 Refrain from Endonasal Operations Unless Strictly Necessary. B. Goldschmidt.

161. **Splenectomy in Treatment of Pernicious Anemia.**—Klemperer and Hirschfeld report two cases of pernicious anemia in which they removed the spleen and marked improvement followed. This brings to six the total number of cases on record in which splenectomy has been done in treatment of pernicious anemia. They based the procedure on the fact that a previous patient with Banti's disease, severe anemia with splenomegaly, developed pronounced polycythemia in a year and a half after splenectomy. The reds then numbered seven and eight millions with hemoglobin over 120 per cent. There are also a number of other cases on record in which polycythemia followed splenectomy done for rupture of the spleen. Eppinger's report of two cases is summarized above, abstract 86. He removed the spleen on the ground that in hemolytic anemia there seems to be a pathologic excessive destruction of the reds in the spleen. As splenectomy has given good results in hemolytic jaundice, he applied the same measure in pernicious anemia and his results were much more favorable than those reported in the *present article*.

It is possible that the splenectomy acts better when the pernicious anemia is of recent date. In the two cases here reported the blood picture changed at once showing an essential influence on the regeneration of the bone marrow. No such powerful reaction on the part of the bone marrow has ever been obtained by any other measure applied in treatment of pernicious anemia. The hope that the splenectomy would stimulate the new production of red blood corpuscles was fully realized, although the blood still has certain features of pernicious anemia, especially the presence of numerous megalocytes. The most interesting point in the case-histories is the immediate flooding of the blood after the splenectomy with nucleated reds, a blood crisis of an intensity never observed before. Time alone will show whether the benefit is durable. The greatest improvement both subjectively and objectively was in the case of a tuberculous woman of 36; the hemoglobin content rose from 30 to 55 per cent. in one month and to 80 per cent. by the second month.

162. **Iodin in Prophylaxis of Diphtheria.**—Strauch applies as a routine measure tincture of iodin to paint the tonsils when diphtheria bacilli are still found in the throat a week after the close of an attack of diphtheria. In sixteen out of fifty cases after one or two applications of the iodin on a cotton pledget no further diphtheria bacilli could be detected; in twenty others none could be found after three applications; in two cases four applications were necessary, and in four other cases, including three with diphtheria of both nose and throat, the bacilli could still be cultivated from the tonsils. He commends this systematic iodin treatment as a useful means to control the further spread of the infection, even though it is not invariably successful. The most striking results were observed in some cases in which chronic bacilli carriers were freed from the bacilli in a few days under the iodin. No harm or by-effects were ever noticed, except the disagreeable but transient taste of the iodin in the mouth.

170 *Dietetic Treatment of Urticaria. H. Salomon.

164. **Fluctuations in Receptivity of the Syphilis Spirochetes.**—Buettner concludes from his extensive research that the activity of the spirochetes and the avidity with which they take up the drugs used in treatment of the syphilis run a parallel course. In the early stages the spirochetes are most active and at the same time most susceptible to drugs. Among the arguments in favor of this view are that drugs are most effectual in the florid stage; also the fact that mild syphilis cannot be cured with correspondingly mild measures, while general paresis is liable to follow the mild early forms; also that the drugs are more effectual in the early than in the later stages; that the cure is not proportional to the amount of the drugs used, and, lastly, the fact that certain germs in other diseases display this same propensity to become less susceptible to drugs in time. Among other conclusions drawn from this research is the necessity for arousing the avidity, stimulating the appetite, of the spirochetes for the drugs. He suggests for this giving small doses of mercury for a few days to activate the virus before commencing the actual therapeutic course. Or one small dose of salvarsan might be given first, before the intravenous therapeutic dose. Activating measures in the form of sweating procedures, iodid, thiosinamin, etc., have long been advocated by some, and he thinks they are logical. He is inclined to regard the Herxheimer reaction as merely the result of activation of the virus.

166. **Acute Necrosis of the Pancreas.**—Gobiet reports seven cases in less than three years in which he has operated on the diagnosis of acute necrosis of the pancreas. Four of the patients had gall-stones and one inflammation of the gallbladder without stones. Five of the patients were inclined to

obesity, but in the two most severe cases the patients were quite thin. In only one case could syphilis be incriminated. The clinical picture is that of sudden and violent intoxication, in the severest cases speedily fatal. The prognosis depends on the amount of toxins produced which in turn depends on the local extent of the process. The diagnosis is based on the symptoms of toxic action accompanied with severe shock and peculiar pains in the epigastrium, more intense than gallstone colic, and the frequent distention of the transverse colon. Operation without delay is imperative—incising and tamponing the pancreas. Even if the biliary passages are diseased, it is not necessary to open and drain them unless there is severe suppuration. Only in mild cases of necrosis of the pancreas is it advisable to operate on the biliary apparatus at the same time. As a rule, it is better to remove the gallstones at a second operation, to prevent return of the pancreas affection.

167. Prophylaxis of Diphtheria.—Delyannis expatiates on the necessity for searching out and isolating the carriers of diphtheria bacilli as the only means to stamp out epidemics. He gives a number of concrete examples to show the small numbers of diphtheria-bacilli carriers and the comparatively short periods during which they require isolation. This renders prophylaxis along these lines comparatively simple and easy. He cites Wolff's experience with endemic diphtheria in two villages, affecting 20 per cent. of the total population and resisting all attempts to stamp out the disease until the bacilli carriers were sought out and isolated when at one stroke the epidemic was conquered and no further cases developed. although all other prophylactic measures were dropped. Delyannis thinks that the same system of prophylaxis should be enforced for diphtheria as for typhoid.

170. Dietetic Treatment of Urticaria.—Salomon writes from von Noorden's clinic at Vienna, to call attention to the striking results he has obtained in treatment of rebellious urticaria by having the patients drop all albumin from their diet for two weeks. In his experience the urticaria did not return after this dietetic restriction for two weeks, although the patients afterward gradually resumed milk, eggs, cheese and meat, still keeping the albumin ration, however, rather below the usual amount. The diet he permitted consisted only of tea, coffee, bouillon, lemon and grape juice, potatoes, rice, cereals and plenty of butter and sugar, and about 200 gm. of bread made of coarse flour.

180. Cancer of the Testicle.—Maragliano urges the importance of removing the lymph-nodes along the abdominal aorta, as they connect directly with those linked with the testicle, as an important aid in warding off recurrence. He reports a case.

181. Mobilization of the Pelvic Mesocolon as Aid in Entero-Anastomosis.—Vignolo calls attention to the advantages of the technic he applied in a recent case and studied further on the cadaver. In resecting a cancer in the colon near the sigmoid flexure, a wide gap was left between the stumps and they could not be brought together until he cut across part of the mesentery of the lower stump at its base. This freed the lower stump so that it could be brought up easily and joined with the other. In two weeks the bowels were functioning practically normally and recovery was soon complete.

182. The Thermo-Cautery Before Plugging Cavities in Bones.—Fioravanti reports only two cases but the results were so unmistakably excellent, as also on rabbits and dogs, that he advises as a routine measure the use of the actual cautery as a preliminary to Mosetig's filling. It aids in hemostasis while it dries out the cavity and helps to sterilize it.

183. Traumatic Abscess in the Liver.—D'Agostini's patient was a boy of nearly 6, who complained of pain in the right side at the point where he had been punched in the side by one of his mates eight days before. He kept on at school for ten days when chills and remittent fever developed and a small tender bunch could be palpated in the side, gradually increasing to the size of an orange. There was no jaundice nor diarrhea nor vomiting. The large fluctuating tumor was opened under ether and smooth recovery followed. The pus had the odor characteristic of colon-bacillus pus. D'Agostini was able to find in the literature only one other case of traumatic liver abscess; this was in a robust man who slept in an iron-framed cot, the hard edge of which traumatized his right side.

GASTROSCOPY *

HENRY H. JANEWAY, M.D.

NEW YORK

It is unnecessary, in a paper attempting to enlist interest in gastroscopy, to emphasize the frequency of cancer of the stomach and how rarely this disease is diagnosed in an early stage. Only one question presents itself for discussion. Is gastroscopy an efficient and practical method of viewing the interior of the stomach? By an efficient method is meant one which permits the details of the mucous membrane of a sufficient portion of the stomach to be seen clearly. By a practical method is meant one which is not dangerous and does not entail too much inconvenience or suffering on the part of the patient, and, perhaps, one which furnishes more information than other existing methods of objective examination.

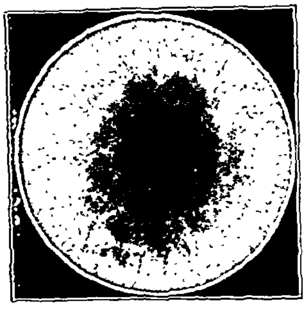

Fig. 1.—Cardiac sphincter—direct view.

No one, for instance, would question the value of inspecting the interior of the stomach or the obligation which rested on the physician of insisting that patients with new gastric symptoms should submit to an examination of this character if he believed that the procedure was really efficient and practical in the sense just defined.

It is the object of this paper to show to the members of this Section how much of the interior of the stomach can be seen, how clearly it can be seen, and with what little inconvenience in the normally formed person.

Although I believe that anyone who witnesses this demonstration would be forced to admit that on this patient, at least, gastroscopy is an efficient and practical method of viewing the interior of the stomach, the fact nevertheless remains that for more than thirty years numerous attempts have been made to improve the technic of gastroscopy without gaining for this method of examination even a small part of that recognition which cystoscopy has acquired. This consideration naturally reflects some doubt on any claim to improvement which would place gastroscopy on a new plane of efficiency.

Figure 1 represents the cardiac sphincter. Figures 2 and 3 represent the entrance to the pyloric region of the stomach at the place of transition from the vertical portion of the stomach to the horizontal portion. Figure 4 represents a view in the opposite direction toward the fundus or cardiac region. It illustrates the anterior and posterior walls of the stomach separated by a central cleft-like cavity. Figures 2, 3 and 4 are seen through an indirect telescope viewing the mucous membrane at right angles to the direction of the instrument. Figure 5 represents the stomach in the direction of the greater curvature viewed directly. It must be quite evident to anyone that, if views of such a degree of clearness can be obtained within the stomach, the method of examination is not only of positive, but also of negative diagnostic value. The character of these views depends alone on efficient illumination. I have tried four other types of telescopes, but have been unable to obtain the satisfactory view of the interior of the stomach here demonstrated until I had constructed the lamp and lens system of the instrument used in this demonstration. The lamp is as large as the caliber of the sheath of the instrument and furnishes sufficient light to illuminate the whole of the distended stomach.

The use of so large a lamp is made possible by the device for pressing it to one side after it has been introduced into the stomach. I have compared its degree of illumination and the views possible by it with those obtained by the indirect type of instruments made on the plan of the indirect cystoscopes and am convinced that the latter type of instrument will not enable one to see distinctly within the stomach. The lens system does not afford a view through a wide angle, but enables the eye to see clearly up to within 4 inches from its surface.

When suspicious appearances are found the direct view telescope may be focused on the area, as illustrated in Figure 5, and a piece removed for microscopic examination. Up to the present I have made a positive diagnosis by one or the other of these methods in twenty cases of cancer of the stomach. The roentgenoscopic examination was negative in two of these cases. The field of usefulness of the Roentgen examination of the stomach and of gastroscopy are not quite the same. But the two methods complete each other well. Roentgenoscopy furnishes accurate information regarding the condition of the pylorus. This is, of course, the most important region of the stomach in which the largest number of ulcers and carcinomas originate. On the other hand, gastroscopy furnishes exact information, both positive and negative, about the condition of the vertical portion of the stomach. This includes by far the largest portion of the stomach and the region of the lesser curvature, but not the region, perhaps, in which the majority of ulcers and cancers originate. It does, however, include a region occupied by a large proportion of cancers and those which

---

* From the Department of Experimental Surgery of New York University and Bellevue Hospital Medical College.

are particularly difficult to recognize clinically or by any other method of objective examination, even including Roentgen cinematography. One can, therefore, see inside the stomach with a degree of clearness which completes in a needed manner other existing objective methods of examination. It is possible, moreover, in the normally formed person, to make the examination without undue discomfort and with safety.

I am convinced that, if proper gentleness and carefulness of technic are exercised, it is possible to diagnose cancer of the cardia simply with the aid of cocainization of the pharynx and without causing pain or an amount of discomfort to which a normal person would object.

Some discomfort, except in rare persons, is experienced and the nervous apprehension of the average patient at the thought of having a rigid instrument inserted into the stomach is such that I have concluded that the examination in a large percentage of patients is more satisfactorily conducted under a general anesthetic. For this purpose we have in intratracheal anesthesia, a new method which makes possible in gastroscopy that which previously has not been possible. For gastroscopy it is superior to intravenous or rectal anesthesia because it prevents any obstruction to the elimination of the ether which may be caused by pressure of the gastroscope on the trachea. It is possible, moreover, to conduct the whole examination after the administration of a small amount of ether under nitrous oxid and oxygen by a method perfected for this purpose and about to be described. I believe that the possibility of conducting gastroscopy under nitrous oxid and oxygen anesthesia introduces a new consideration in gastroscopy which, if it proves uniformly successful, will remove the last objection to the routine use of this method of examination on the ground of discomfort to the patient. Certainly, if it is possible to examine the interior of the stomach in a patient anesthetized with an anesthetic associated with so few unpleasant after-effects as those which follow nitrous oxid anesthesia, there should be no objection to the routine application of a gastroscopic examination when what it reveals may mean so much to the patient.

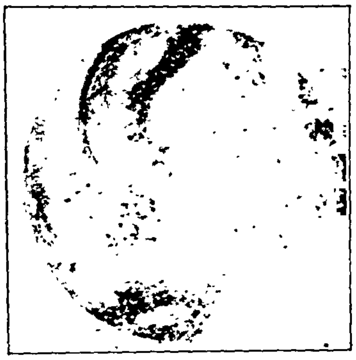

Fig. 2.—Entrance to the pyloric region of the stomach at the place of transition from the vertical to the horizontal portion—indirect view.

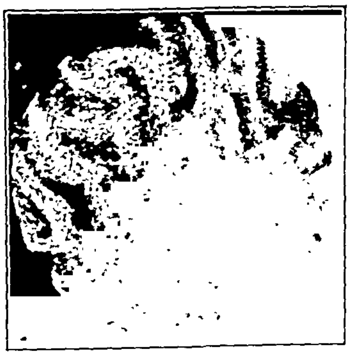

Fig. 3.—Entrance to the pyloric region of the stomach at the place of transition from the vertical to the horizontal portion—indirect view.

As regards the safety of gastroscopy, are there any dangers connected with passing a rigid tube into the stomach? Dr. Chevalier Jackson long ago proved that the procedure is devoid of danger; and how can it be otherwise if the eye of the observer is always kept on the distal end of the instrument? If the end of an instrument which is inserted into the esophagus and then into the stomach is never allowed to progress except where the folds of mucous membrane fall away before it by air distention in its passage down the esophagus, how can any injurious trauma be caused? Except in the case of one patient at the very beginning of the work when my technic was faulty, I have never had any unpleasant consequences.

The late diagnosis of gastric cancer, particularly of cardiac cancer, has long been a blot on the reputation of medicine. I believe that we now have two methods, Roentgen cinematography and gastroscopy, which do not cover the same field, but which complement each other, and by which it is possible to make the diagnosis of carcinoma of the stomach when the presence of this disease is suspected. It is no longer a question of inability to make the diagnosis, but, in the words of Dr. Jackson, of "looking and seeing."

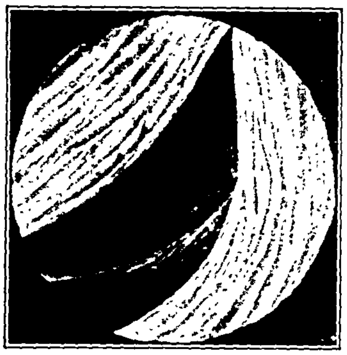

Fig. 4.—View toward the fundus or cardiac region—indirect view.

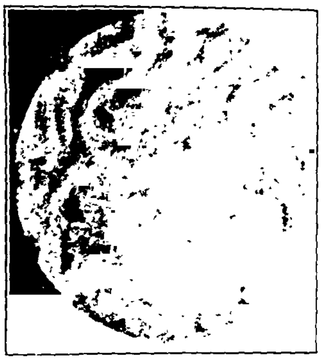

Fig. 5.—The stomach in the direction of the greater curvature, viewed directly.

It may perhaps be a question of the patient's complaining of symptoms early enough, but if gastroscopy and roentgenoscopy are made a routine in cases in which the diagnosis of cancer is among the possibilities, a large proportion of carcinomas of the stomach will be found in a stage in which it is possible to do something for them. Of not less importance, perhaps, is the consideration that we shall be discharging an obligation which we owe these patients.

It is surely desirable to be in possession of the information afforded by these two methods of examination before resorting to exploratory incision. If this rule is followed the exploratory operation may prove unnecessary, or, if this is indicated, the surgeon will be in a better position to proceed with a radical operation.

ONE HUNDRED CASES OF WATER-TRAP STOMACH *

G. REESE SATTERLEE, M.D.
AND
LEON THEODORE LeWALD, M.D.
NEW YORK

In the examination of a patient with an apparently severe digestive condition, the first essential point is to determine which part of the digestive tract is particularly to blame for the symptoms. This can be accurately ascertained only by means of a most searching roentgenologic examination. Diagnosis by symptoms, as well

---

* From the Edward N. Gibbs Memorial X-Ray Laboratory, New York University, and the Roentgen-Ray Department of St. Luke's Hospital, New York.

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

as by many of the clinical tests, has been found very misleading. In a large number of cases a general visceroptosis can be diagnosed in the course of a physical examination, especially in multiparas with lax abdominal walls and protuberant abdomens, but even here mistakes can be made, as proved by roentgenograms.

There are two theories of ptosis generally accepted:

1. Glénard's theory, according to which it is a nutritional disease and "hepatic diathesis" with atrophy and prolapse of the small intestine. This would practically condemn the sufferer to everlasting invalidism.

2. Stiller's theory, according to which it is a universal asthenia, characterized by weakness and laxity of the viscera, and is manifested by degeneration. Surgical procedure would, therefore, be useless. Against this theory is the fact that enteroptosis is rare in men and frequent in women.

We believe the water-trap stomach to be a morphologic entity, a deformed organ which gives rise to a certain definite train of symptoms.

The factors generally acknowledged as causing the disease are misuse of corsets, tight lacing and changes due to pregnancy and childbirth. These factors are undoubtedly very strong, but the congenital side has usually been overlooked or underestimated. Rövsing has divided the subject into virginal and maternal coloptosis. Virginal coloptosis, he says, begins in the first or second year after puberty, and is characterized by persistent constipation, cardialgia and the eating of many small meals.

This condition, we believe, is due largely to congenital causes, such as faulty development of the gastro-intestinal tract associated with abnormally long mesenteries of the stomach or colon, and the very common condition of a long pelvic colon. Given these conditions, bad habits and bad intestinal hygiene may bring on the symptoms found in these patients. The influence of corsets and tight lacing have, we believe, been greatly overestimated. As a rule, when one asks the question as to tight lacing the patient replies, "No, I never could lace tight; the pressure on my stomach made me too uncomfortable." On the other hand, there is the other type in which tight lacing may have been one of the strong factors, as shown by the depression of the ribs and the elongated flattened liver.

In these virginal cases the patients show almost invariably a very long bony thorax and narrow costal angle, and a comparatively large pelvis. There is too little room in the upper abdomen for the organs that naturally belong there. The abdominal muscles in these patients are usually well developed, with firm recti and no lax bulging abdominal wall. These patients often have the type of organ about to be described—the water-trap or drain-trap stomach.

The chief characteristic of this stomach is the relatively high, but normally placed, pyloric outlet, which is well held up by the gastrohepatic ligament and the retroperitoneal tissue to the spine. The vertical diameter is always long. In sixteen of our cases which we studied in detail, the longest diameter, usually nearly vertical, varied from 23 to 38 cm. (from 9 to 15 inches), averaging 26 cm. (10½ inches). The distance from the junction of the first and second portions of the duodenum to the most dependent portion of the greater curvature is abnormally long. This portion of the stomach, briefly referred to as the pyloric arm, varied from 13.5 cm. (5¼ inches) to 24 cm. (9½ inches). In other types of stomach this distance varied from 4 cm. (1½ inches) to 8 cm. (3 inches), which length is in itself sufficient to rule out deformity of water-trap type. The average length of the pyloric arm in the sixteen cases referred to was 16.5 cm. (6½ inches). The distance from the umbilicus, or from a line drawn across the upper level of the iliac crests varied from 7.5 to 20 cm. (from 3 to 8 inches). This distance in normal stomachs averages 3.5 cm. (1½ inches). These measurements were made on roentgenograms taken from one to five minutes after the administration of a bismuth meal consisting of 90 gm. of bismuth subcarbonate suspended in 600 c.c. of fermented milk. The water-trap stomach might almost be considered as a ptosed organ, with the first portion of the duodenum and the pylorus fixed in proper position, giving the characteristic long pyloric arm and resemblance to a water-trap. The colon in the sixteen cases cited was ptosed in amount corresponding to the degree of ptosis of the greater curvature of the stomach.

In practically every case of water-trap stomach the colon is either ptosed or there is a very long loop in the transverse portion, which corresponds in contour to the greater curvature of the stomach. In our classification of colons we consider the colon ptosed only when the cecum and hepatic flexure are ptosed, for it is the exception to find the colon high when the cecum is ptosed.

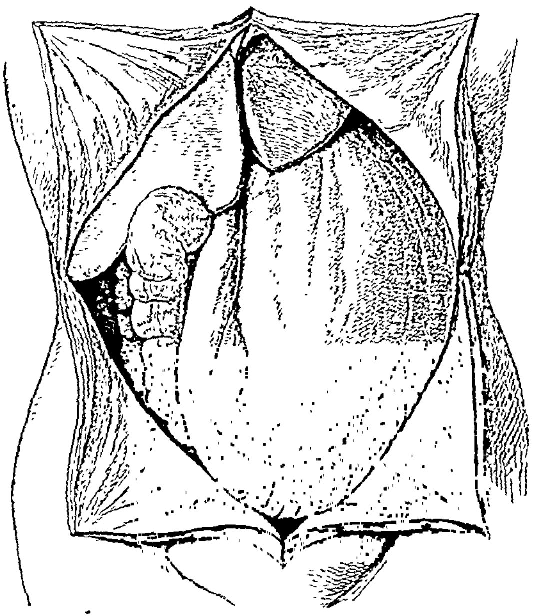

Fig. 1.—Water-trap stomach; from an anatomic dissection.

This paper is entirely too short to give the detailed reports of the one hundred cases studied, so we give a summary of the important facts merely.

TABLE 1.—ANALYSIS OF ONE HUNDRED CASES OF WATER-TRAP STOMACH

	No. of Cases
Males	4
Females:	
Married	47
Single	49
Between ages of 15 and 19	4
Between ages of 20 and 29	28
Between ages of 30 and 39	37
Between ages of 40 and 49	20
Between ages of 50 and 59	10
Over 60 years	1
Total	100
History of vomiting obtained in only 35 cases.	
Residue shown	55
Colon ptosed shown	84
Constipation shown	45
Operated on	18

It will be noted that the water-trap deformity is extremely rare in men. It is of paramount importance to note that child-bearing can have little or no relation to the lesion, because half of our cases have occurred in unmarried women. Only four out of the sixteen cases especially studied were multiparas. While these patients have invariably suffered for years with symptoms erroneously diagnosed as neuralgia of the stomach, ulcer of the stomach, nervous indigestion, neurasthenia or dyspepsia, the limit of endurance has been reached only after about fifteen years of suffering. And while we have observed the water-trap deformity of the stomach in early youth and a tendency to the condition in childhood and often in infancy, as shown by roentgenograms, the usual time at which these patients present themselves for radical treatment is between the ages of 30 and 40. It is conceivable that this condition of the stomach is aggravated by faulty living, improper food and constipation, but it is more probable that the true water-trap stomach has a close analogy, for example, to inguinal hernia, which is now universally conceded to be of congenital origin with trauma superimposed. If this be true, it is at once evident that the water-trap deformity when of marked degree is as surely amenable to surgery as is an irreducible hernia. Vomiting is shown by Table 1 as infrequent, and was rarely a marked symptom. Residue in the stomach was much more frequent, and part of the symptoms could often be traced to this condition. Coloptosis was nearly always present, although about 16 per cent. showed no ptosis, and 4 per cent. showed an abnormally long colon without any ptosis. Constipation is, apparently, not so strong a factor as is generally supposed. We know that constipation is improved and, in some cases, relieved by suspension of the stomach and colon. There is ground to believe that this may in part be due to the increased amount of water turned into the colon, or to reestablishment of the normal activating processes of the peristaltic enzymes. Water has been shown, experimentally, by Draper[1] to be absorbed vicariously from the stomach under conditions of intestinal obstruction. When these stomachs are successfully operated on, they empty completely within a few hours, so that the water which previously was absorbed from the stomach now has a chance to reach the colon and thereby prevent constipation.

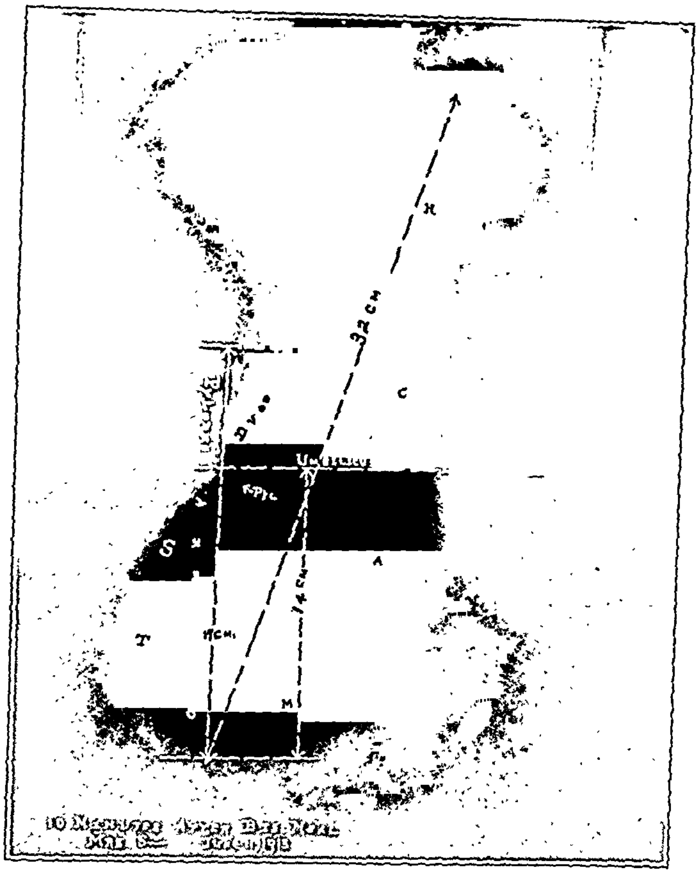

Fig. 2.—Typical water-trap stomach. Pyloric arm 19 cm. (7½ inches).

Furthermore, in considering the shape and position of the viscera, and in studying the symptomatology, there appeared to be a very constant drag of the ptosed, hollow viscera on the visceral nerves and blood-vessels, and this drag must be an important symptomatic factor. Another factor is the presence of a residue in the stomach long after the usual emptying time. Such a residue was demonstrated in the roentgenograms in 50 per cent. of the cases. The muscular action and the resulting emptying coefficient in practically all of these patients are below par.

Eighteen of the one hundred cases were treated by abdominal section. As these cases are of extreme interest, one case will be reported in detail:

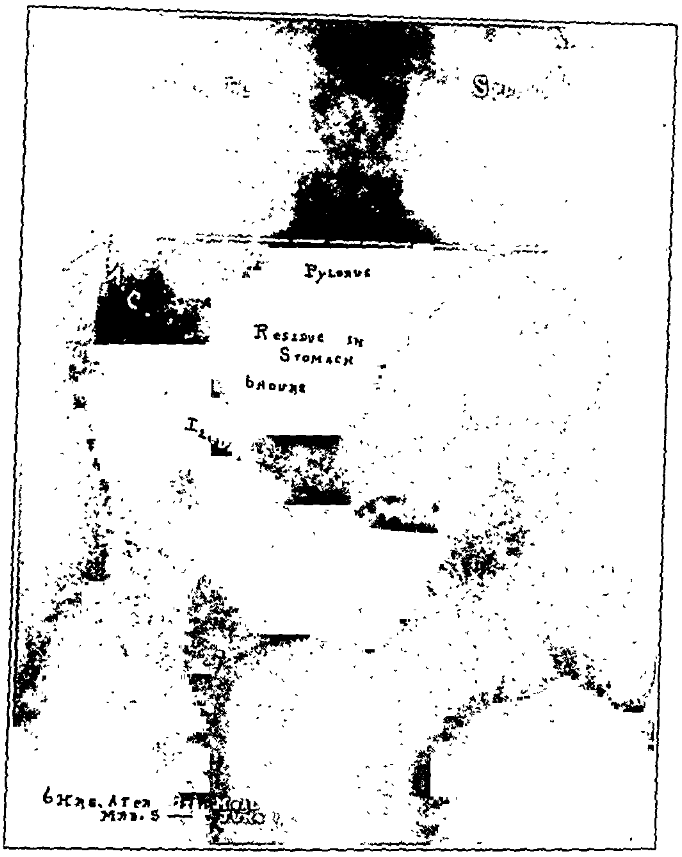

Fig. 3.—Same case as Figure 2. Large residue. Findings confirmed two weeks later, followed by an immediate operation.

Mrs. L. E., aged 31, nullipara, with severe progressive neurasthenia and hysteria for years, variously diagnosed as nervous indigestion, neurasthenia, hysteria, anemia, etc., when seen, had periodical attacks of vomiting occurring every two weeks. She had lost about 40 pounds and was extremely emaciated. After one severe vomiting attack, lasting two days, roentgenograms showed a very marked water-trap stomach and coloptosis. Medical treatment had absolutely no effect, and after another severe attack of vomiting with bright blood in the contents, laparotomy was performed. The condition as outlined by the roentgenograms was verified, the lesser curvature being found well below the umbilicus and the pyloric extremity fixed in normal position.

The ventral surface of the stomach was sutured to the abdominal wall and the mesentery of the transverse colon was also sutured to the abdominal wall just above the level of the umbilicus. The results have been very satisfactory. The gastric symptoms have gradually disappeared, the neurasthenia and hysteria are completely cured, the constipation is relieved and there has been a gain in weight of 15 pounds. Roentgenoscopy one year after operation showed the stomach and colon in place, and to-day, two years after operation, the patient is well and without medical attendance.

---

[1] Draper: Personal communication.

In practically every case in which a thorough form of suspension technic was employed the patient has, up to date, done well. Operation is apparently the only rational treatment in certain selected cases. Gastropexy and colopexy are safe procedures. Gastro-enterostomy may cure, but is not to be preferred. Suspension will give instant and possibly permanent relief, if a careful and well-studied technic is followed. The symptoms that have been relieved are the drag, intestinal indigestion as shown by flatulence, neurasthenia and in many cases constipation. In four of these operative cases previous appendectomy had given no relief in symptoms. In the sixteen special cases, previous appendectomy had given no relief to symptoms in five cases. In nine cases the appendix was not removed during the operation, and the results have been good. In one case, with a water-trap stomach, appendectomy alone without suspension of the stomach was performed with no improvement following the operation. Later a gastro-enterostomy was performed which relieved the patient's sufferings.

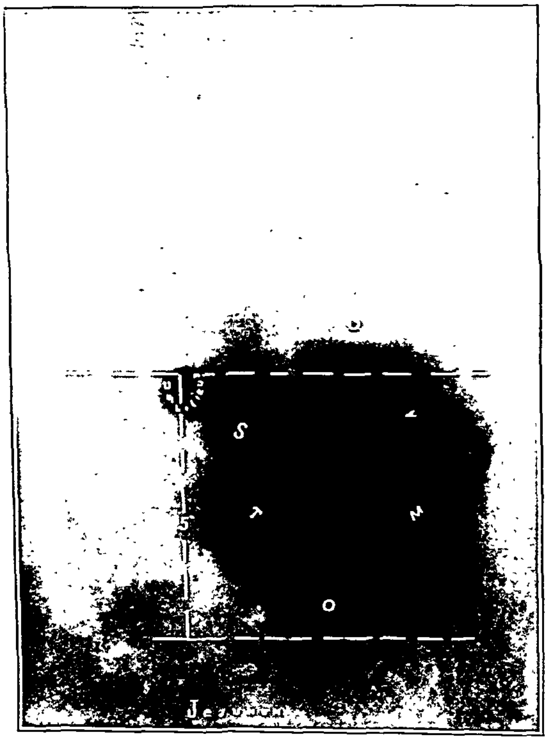

Fig. 10.—Miss M. W., aged 30. A case of well-marked water-trap stomach with residue.

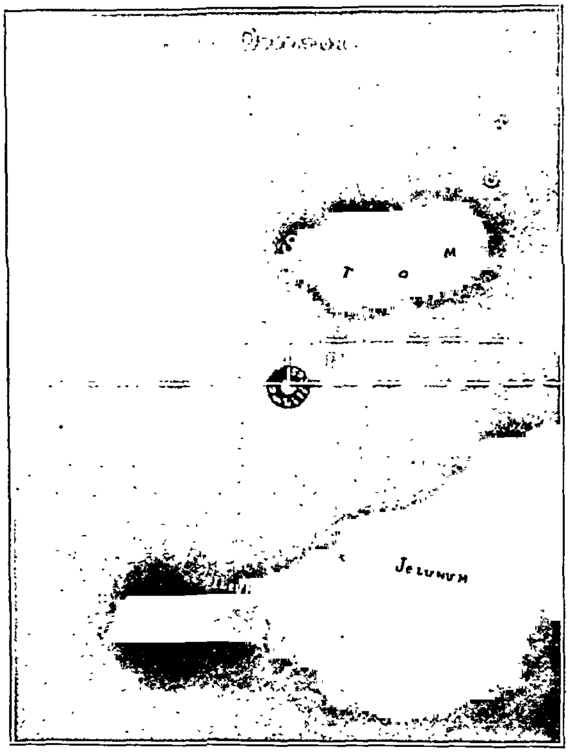

Fig. 11.—Same case as Figure 10, after operation—gastropexy and colopexy. Also appendectomy and fixation of both kidneys.

MEDICAL TREATMENT

After localization of the trouble by roentgenoscopy, the examination is completed by means of analysis of gastric contents, feces and urine. After the exclusion, then, of the more serious and perhaps operative conditions of ulcer, malignancy or obstructions, and since ptosis is probably the most important factor, the first thing is to endeavor to relieve this condition. Operation is indicated in special cases, which will be described later. Nearly every patient will be benefited and sometimes entirely relieved by wearing a properly fitting abdominal belt or corset. The selection is important. When there is small discrepancy between the circumference at the waist and that at the pelvis, a corset with an abdominal flap (a surgical corset) will act well; but when the conditions are reversed, as in one patient who measured 22 inches at the waist and 34 inches around the pelvis, the corset is inefficient. In patients with this figure we have used a web abdominal support reinforced with a colon pad. This is also the type of support used for male subjects.

The corset and supports should be applied the first thing in the morning, with the patient on the back and pelvis elevated, and should be worn all through the day as long as the patient is on the feet, and removed before retiring. Another aid is to raise the foot of the bed, gradually, from 1 to 5 inches or more. This takes advantage of nearly one-third of the twenty-four hours to allow the stomach and colon to gravitate to their proper places. With a water-trap stomach, the patient should lie on the right side, with the foot of the bed slightly elevated, for about an hour after meals. This allows the stomach to empty, and it is of material aid. One patient with this condition gained 17 pounds in six months following these instructions, even without an abdominal support. The effect after a short time is to relieve the feeling of drag in the abdomen and also aids the constipation.

The treatment of the constipation is the next step. This is the most difficult procedure. Regulation of the diet by avoiding the constipating foods and giving those most likely to have a laxative effect should be carried out. All laxative drugs should be stopped, and the most that should be allowed is an occasional enema. The colon should at first be thoroughly emptied in the following manner: With the patient in the knee-chest position, from 6 to 8 ounces of warm cottonseed oil are given by rectum the last thing at night, and allowed to remain in the bowel over night. The next morning the bowel is flushed out first with 2 quarts of ox-gall solution, from 2 to 4 drams to the quart, which is followed by two quarts of normal saline solution. This process is repeated in three positions: (1) on the back; (2) on the side, and (3) in the knee-chest position. The immediate results may not be much, but in a few hours there is usually a copious evacuation. In some cases, when the fecal matter is high up, 1 ounce of castor oil every night for three nights is given.

The correction of the stomach abnormality is next considered. When the hydrochloric acid content is diminished or absent, prolonged administration of dilute hydrochloric acid is often of great assistance and may alone offset the constipation. After employment of this treatment for several months the gastric juice has returned to normal.

Massage regularly applied to the colon, which has been definitely mapped out by roentgenoscopy, is very helpful. Vibration, carried out in the same manner, is even more helpful in some cases. Among the preparations given by mouth, agar-agar, powdered or granulated, has been the most successful. This should be given in teaspoonful doses three times a day, with meals. If there is stasis in the pelvic colon, this portion of the bowel should be cleaned out at regular intervals.

The question of exercise should be regulated by the amount of ptosis. In severe ptosis, overexercise, especially without abdominal support, does harm. Moderate exercise and fresh air will do much more good. Patients with ptosis in which sedentary life and nervous influences play an important part, should live where outdoor life will help to keep them in good condition.

SURGICAL TREATMENT

The indications for and against operation may be summarized as follows:

1. Care should be taken not to operate on a simple, ptosed stomach, with or without dilatation. This rule is subject to occasional modifications.
2. The typical water-trap stomach of mild degree which does not yield to medical treatment should be operated on.
3. The typical water-trap stomach of marked degree, which shows a large residue in the stomach after six hours, should be operated on when diagnosed.

CONCLUSIONS

1. Water-trap stomach is a morphologic entity which gives rise to a certain definite train of symptoms.
2. Its origin is probably embryologic and developmental.
3. It should be distinguished from a simple gastroptosis, with or without dilatation.
4. It occurs most frequently in women, but as frequently in nulliparas as in multiparas.
5. It is not infrequently wrongly diagnosed as ulcer of the stomach or duodenum.
6. Its exact diagnosis is impossible without the aid of roentgenoscopy.
7. In the mild grades medical treatment may be sufficient (analogous to the treatment of a hernia by means of a truss).
8. In severe grades operation offers a means of radical cure (analogous to the radical cure of hernia).
9. In the most severe grades operation is life-saving (analogous to the operation for strangulated hernia).

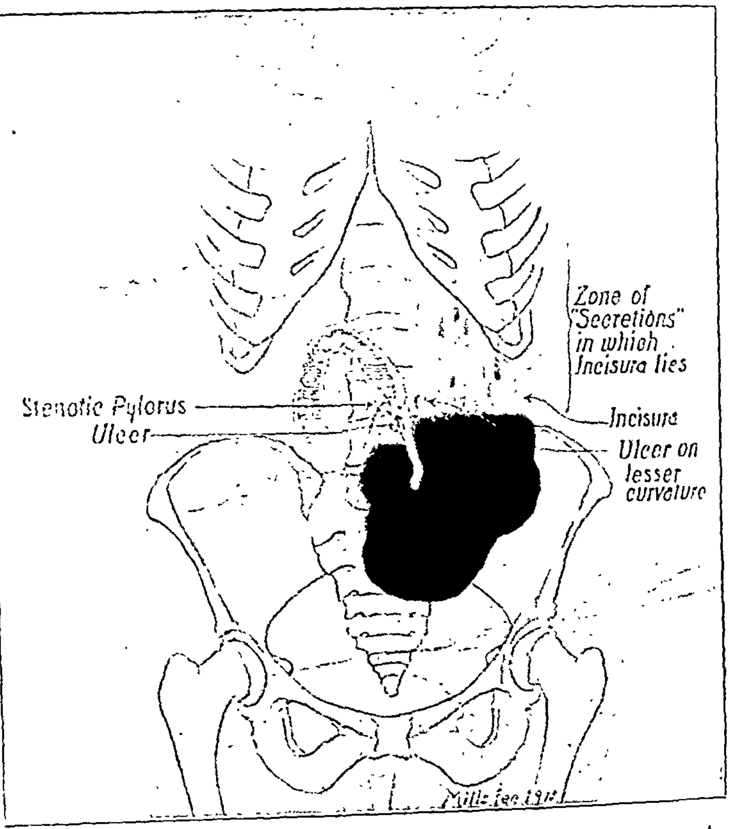
POINTS OF VALUE IN ROENTGENOSCOPY OF THE GASTRO-INTESTINAL TRACT *

R. WALTER MILLS, M.D.
Instructor in Medicine, Washington University Medical Department
ST. LOUIS

The ordinary methods of physical examinations have never been satisfactory when employed to determine the normal and pathologic topography, conditions and activities of the gastro-intestinal tract. Percussion, on account of the abdominal gases and solids, furnishes only the crudest information and is often actually misleading. Auscultation rarely furnishes evidence indicative of specific conditions; there are no normal sounds of constancy that may act as a means of comparison. Inspection furnishes no information not better elicited by palpation, with the exception of the observation of visible peristalsis. Palpation is of much value when suitable conditions exist.



Zone of "Secretions" in which Incisura lies
Stenotic Pylorus
Ulcer
Incisura
Ulcer on lesser curvature

Fig. 5.—Schematic drawing from fluoroscopic tracing and roentgenograms showing a compensated dilatation due to pyloric ulcer obstruction. The stomach shows approximately normal form and position, though dilated, a true megalogastrium (compare Fig. 8). An incisura occurred on the greater curvature opposite its ulcer, and above the level of the bismuth, necessitating palpation for its (fluoroscopic) visualization (see Fig. 6). The case illustrates the value of the Roentgen-ray in establishing and locating multiple ulcers.

Into this situation is now introduced a method approaching precision for the purposes mentioned—the visualization of the gastro-intestinal tract by the Roentgen ray through the ingestion of an opaque substance, usually bismuth—a method which appeals to the most accurate of the senses, sight, and at once accomplishes much that we have been attempting to force from the ordinary methods of physical examination.

It is my object to review those points in gastro-intestinal roentgenoscopy which seem best established and of

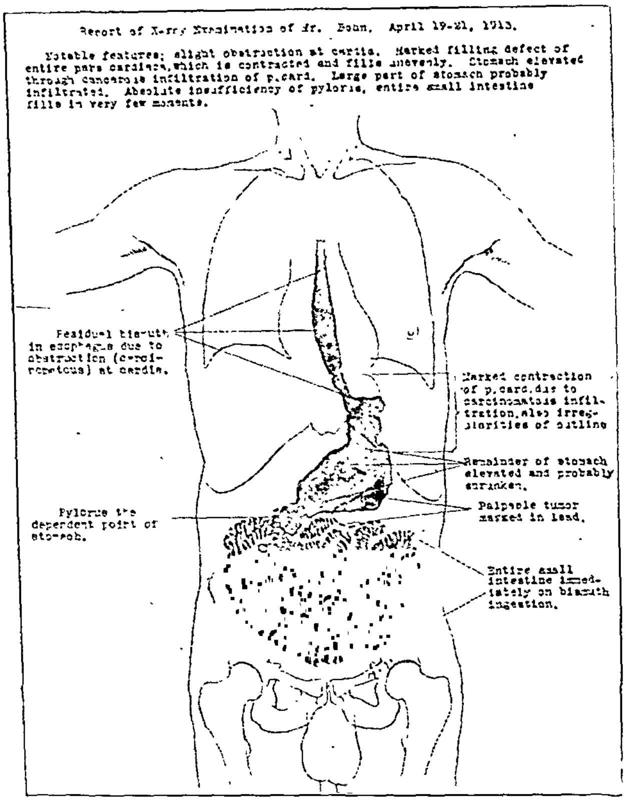
* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

* Because of lack of space, this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints.

most value. The cases shown are from the Washington University Hospital and Outpatient Department. I desire to thank Drs. Dock, Murphy and Myer, from whose services the cases have been largely recruited, for permission to use them.

Roentgen examination of the esophagus gives the most accurate and constant findings of any part of the alimentary tract. Its chief value is in conditions resulting in obstruction or in those in which diverticulum is present. The point and degree of an obstruction may be located; often information is afforded as to its nature and extent by changes in the form of the esophageal lumen, by the size and form of the dilatation, or by hyperperistalsis proximal to the obstruction.



Report of X-ray Examination of Mr. Bohn, April 19-21, 1913.

Notable features; slight obstruction at cardia. Marked filling defect of entire pars cardiaca, which is contracted and fills unevenly. Stomach elevated through cancerous infiltration of p. card. Large part of stomach probably infiltrated. Absolute insufficiency of pylorus, entire small intestine fills in very few moments.

Residual bismuth in esophagus due to obstruction (carcinomatous) at cardia.
Marked contraction of p. card. due to carcinomatous infiltration, also irregularities of outline
Remainder of stomach elevated and probably shrunken.
Pylorus the dependent point of stomach.
Palpable tumor marked in lead.
Entire small intestine immediately on bismuth ingestion.

Fig. 11.—Hospital report showing reduction in size of stomach and deformity as a whole resulting from general carcinomatous infiltration. Insufficiency of the cardia (esophageal regurgitation) as determined later at necropsy and not stenosis of the cardia as indicated on the report. Also extreme insufficiency of the pylorus (entire small intestine filled almost instantaneously) are manifested. Post-mortem two months later showed small intestine canalizing a cancerous mass (colloid) and that the "palpable mass" corresponded to a mass of cancer-infiltrated omentum; note that in the figure it does not register with the stomach.

In uncomplicated diverticulum, marked localized extra-esophageal retention occurs with little interruption as to the continuity of the bismuth stream through the lower esophagus and a gastric filling in approximately normal time.

It is difficult to obtain a plate that shows the diverticular efferent stream (Fig. 1). In carcinoma, characteristic findings are localized obstruction in the passage of bismuth through the esophagus, retention and dilatation above, and irregularity at the esophageal lumen at or below this point (Fig. 2). Obstruction at the cardia is manifested by gross unlocalized esophageal retention and varying grades of dilatation and hyperperistalsis. Esophageal retention due to aneurysm or pressure from other extra-esophageal cause may be detected; visualization in this way of the esophagus may be of aid in determining the topography of the impinging structure.

The Roentgen ray has radically changed our ideas with regard to the form and position of the stomach. The stomach extends far lower and is more vertical in most persons than was supposed. It is fixed only at the cardia and at the first portion of the duodenum by the gastrohepatic ligament. There is no gastroptosis; the cardia is never ptosed. In so-called gastroptosis we have a pendulosity, a sagging of the middle portion of the stomach, and a pyloroptosis dependent on atony, and a congenital or acquired lack of normal intra-abdominal or abdominal muscular support, or skeletal deformity (Fig. 3).

The stomach is an organ of the widest variation as to form and position in different persons; this is true also with regard to gastric tonus. By tonus we mean that resilience or elasticity of the living stomach under natural conditions which enables it to hold up its contents in a columnar form, one of the chief factors in giving form to the stomach. Lack of tonus, atony, is accurately shown by the Roentgen ray (Fig. 15). The Roentgen ray has shown that the stomach is no larger than its solid or liquid contents, no matter how small, and that when empty, in life under normal conditions, it is tonically contracted, probably to a tubular form. The observation of gastric peristalsis by the Roentgen ray is a method of precision, but is a most difficult one and so far relatively unfruitful in its interpretation.

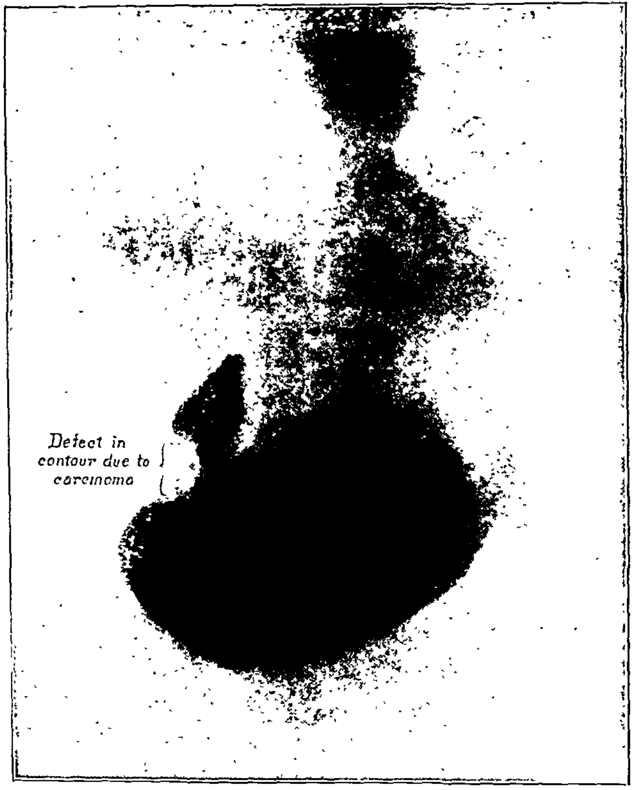


Fig. 12.—A filling defect due to the small localized carcinoma immediately proximal to and slightly involving the pyloric ring. Carcinomatous degeneration of an old stenosing pyloric ulcer is suggested by the degree of dilatation (i. e., increase in the right median distance) which is greater than I have seen developed in a recent (carcinomatous) condition. Resection by Dr. N. B. Carson. Referred by Dr. Walter Fischel from the Skin and Cancer Hospital. Very slightly retouched.

Each person possesses a stomach that fits his body; there is no normal type of stomach; I believe that the form of the stomach under normal conditions may be anticipated from an observation of the person's physique and strength. The same is true of gastric tonus and the rate of motility or clearance. In persons of sthenic habitus the stomach is of high and more transverse position, of strong tonus and quick motility. In those of asthenic habitus, so-called congenital enteroptotics, it is low in position, vertical, weak as to tonus, and slow in motility. If, however, it adequately serves its purpose, it is normal for its owner. Views of the stomach from different angles are of use in locating pathologic lesions (Fig. 4).

In ulcer of the stomach the Roentgen ray may give characteristic findings. The proportion of cases in which this occurs is probably about 75 per cent. In the future it will be larger. These are chiefly changes in tonus with resulting anomalies of form, or primary changes in form. Ulcer of the approximately vertical portion of the stomach gives most of the definite findings.

Ulcer of this location may cause a sharply localized tonic spasm of the circular muscular fibers at its level,

The crater of an ulcer may be visualized by the Roentgen ray through virtue of the bismuth it contains, provided that it is situated on the periphery of the stomach shadow or that it is possible to so turn the patient as to silhouette its outline (Fig. 7). Chronic penetrating ulcer results in spectacular roentgenoscopic findings. Ulcers penetrating adjacent parts thus allow access of the gastric digestants to unprotected tissue. A cavity adventitious to the stomach may thus be excavated. Such a diverticulum will be graphically shown by the Roentgen ray as a small usually circular shadow capped by a gas-bubble without the main stomach mass. Organic hour-glass stomach can be diagnosed by the Roentgen ray. The picture is that of two atypical gastric ventricles connected by an irregular isthmus. The filling of the lower sac takes place slowly by seepage.

Ulcer of the pars pylorica seems often to result in no characteristic changes unless obstructive. If ulcer or its cicatrix obstruct the pyloric lumen a dilatation of the stomach results which the Roentgen ray graphically shows. If the obstruction be uncompensated the stomach enlarges in all its lower lateral diameters, especially in the right median distance (Fig. 8). If there be a compensatory hypertrophy of the gastric walls, the stomach seems, certainly in some cases according to my experience, to resume its normal position and form, though dilated, a true megalogastrium (Fig. 5).

Little has been learned of gastric ulcer by a study of gastric peristalsis; considerable from a study of its resultant motility. In pyloric obstruction peristalsis is periodically markedly increased, though in the lesser grades not more so than in certain non-obstructive conditions. Normally the stomach empties itself of a bismuth meal in from one and one-half to six hours, depending primarily on the type, as to physique, of the person. In asthenics this time may be extended (bismuth media). In ulcer, motility is sometimes delayed; in pyloric obstruction for obvious reasons, and in non-obstructive ulcer at times on account of true pylorospasm due to superacidity. In organic obstruction I have seen a considerable amount of bismuth in the stomach forty-five hours after ingestion. The physique of the individual must be considered in judging motility.

The Roentgen ray is of value in locating and otherwise correlating for diagnostic purposes painful and pressure sensitive points due to ulcer. Such pressure sensitive loci are due either to reflex hyperesthesia in the abdominal wall or an irritation of the parietal peritoneum through ulcer-evoked perigastritis. A reflex pressure-sensitive locus does not overlie an ulcer, or does so only as a coincident. The parietal peritoneum can localize an irritation, so clinical symptoms of perigastritis add much to the probability that a pressure-sensitive point overlies an ulcer. This is still more probable if the point registers with a site suggested by roentgenoscopy as the seat of ulcer. The great majority of pressure-sensitive points in ulcer subjects are found to fall without the shadow of the filled stomach. They are reflex, and so far of no clinical value.

The most valuable single feature of gastro-intestina roentgenoscopy is that it offers aid in the early diag nosis of cancer of the stomach; yet it is unfortunatel true here as in the clinical examination that the earlie the growth the less positive its manifestations. Gastri cancer manifests itself roughly as either an irregularit of outline, at times amounting to an obliteration of som portion of the stomach (Fig. 9); as a local excavatio on the periphery of the bismuth shadow (Figs. 10 an 12), or as an irregular diminution in the size the shadow as a whole (Fig. 11). It may be evinced only by a change in density of the bismuth shadow. Associated with any of these, confusing tonic spasmodic contractures may occur excited by involvement and irritation of the gastric circular muscular fibers (Fig. 10). One cannot in a few moments even suggest the possibilities. Figure 12 shows a very slight defect due to early carcinoma. The diagnosis was aided by clinical evidence of pyloric obstruction, though probably no operation would have been attempted but for the roentgenoscopy, which showed most of the gastric wall intact. A very small cancerous mass was found at the spot indicated, an ideal case for operation.

I have attempted to develop a method for correlating abdominal physical findings, such as tumefaction, pressure-sensitive loci or areas of visible peristalsis, with those of the Roentgen ray. Such clinical findings are marked in lead on the patient's body before the roentgenoscopy; especially interesting results are obtained in the case of tumefaction in or near the stomach. Figures 3, 9 and 11 illustrate the method of recording these findings for hospital histories; they are made from routine reports. Each figure is exactly that of the patient in question reduced to scale; the stomach and intestines likewise. All abdominal landmarks, physical and Roentgen ray findings bear their actual relations.

Other gastric tumors give findings similar to those of carcinoma. Figure 13 shows an obliteration of the pars media by syphilitic infiltration resulting in marked obstruction.

Ulcer of the duodenum gives less valuable Roentgen-ray evidence than does gastric ulcer. Most duodenal ulcers occur in the first portion of the duodenum, recognized roentgenoscopically as the "cap." A persistent deformity of this cap may indicate ulcer. The cap may be drawn out of position or deformed by adhesions secondary to ulcer periduodenitis. Overprompt initial gastric motility has been repeatedly mentioned as an indication of duodenal ulcer, possibly due to an interference with the tonic closure of the pyloric sphincter that exists before the onset of the later, more powerful, pyloric acid reflex. It is so far the most valuable indication of duodenal ulcer. Such hypermotility occurs, however, in other conditions, notably those causing hypo-acidity. The form of the stomach in duodenal ulcer seems different from that of gastric ulcer, being higher and more transverse. Hyperperistalsis is another usual accompaniment. A pressure-sensitive point overlying the ulcer seems more constant in duodenal than in gastric ulcer. It can only be a reflex whose registration with the ulcer region is coincident.

Stenosis of the duodenum, if distant from the pylorus, may be diagnosed by the Roentgen ray. In stenosis large rhythmical ball-like waves may be seen proximal to the point of obstruction. Figure 15 shows these due to obstruction of the terminal duodenum from involvement in an ulcer mass. Figure 16 shows apparently a dilatation of the stomach in an infant, in reality a common dilatation of duodenum and stomach, due to a congenital stenosis in the third portion of the duodenum.

The points of value with regard to Roentgen-ray examination of the jejunum and ileum are so far practically limited to lesions causing obstruction and the observation of motility. Unusual difficulty is offered by the attenuation of the bismuth column in the small bowel and the rapidity of its passage. Certain findings lead one to entertain the idea that the rate of gastric clearance controls the rate of passage through the small intestine. I have seen a case in which the entire small intestine was almost instantly canalized when extensively involved by colloid carcinoma (Fig. 11). Another in which this occurred in seven minutes as the result of an overpatent gastrojejunostomy (Fig. 17).

The field opened by the Roentgen ray for the investigation of conditions of the colon is so vast and as yet so far from exhausted that even generalities are difficult. Investigations are conducted after, or better, during the administration of a bismuth-containing enema, less desirably by the feeding test except in cases of obstruction. A bismuth enema given with an ordinary rectal tip will in a few moments canalize the entire colon, proving the high enema an absurdity. The colon, like the stomach, is subject to great anatomic variation, especially as to length and the arrangement of its various parts; the two flexures alone are fixed. So-called redundancy is probably normal for persons in whom it occurs. Figure 18 shows the cecum and proximal transverse colon adherent in an old appendiceal abscess mass.

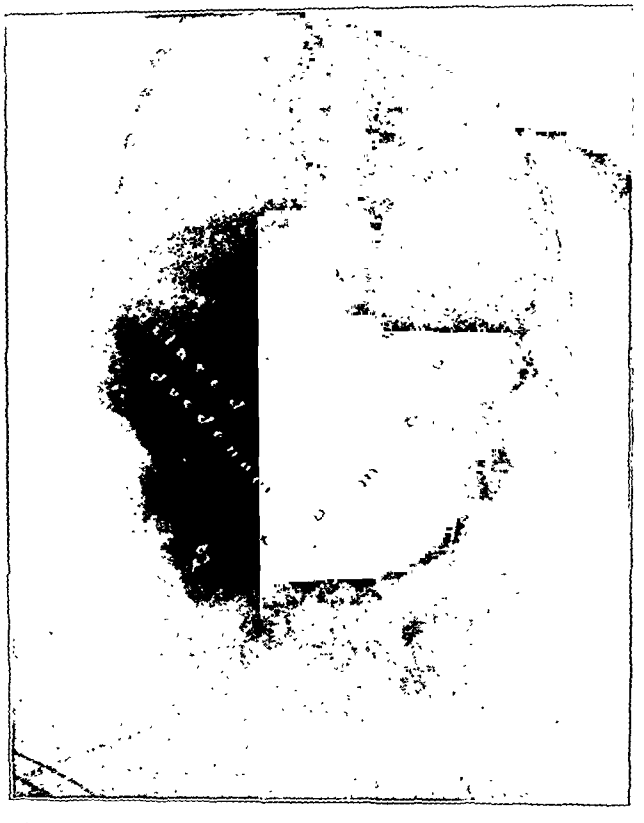

Fig. 16.—Roentgenogram showing findings in a case of common dilatation of stomach and duodenum in an infant, due to a congenital obstruction in its third portion. In other plates taken later the duodenum is shown as filled, while most of the stomach is empty.

The different types of constipation give interesting findings on roentgenoscopy both as to the portion of the colon in which the motor delay occurs and the associated anomalies of tonus. In spastic constipation, the hypertonicity is graphically indicated. Probably the two most valuable points so far established in Roentgen-ray examinations of the colon are that it affords a means of studying the motility of the different portions of the colon, and of determining points of obstruction, both benign and malignant.

It is self-evident that the Roentgen ray may be of great aid to the internist and surgeon in the diagnosis of gastro-intestinal affections. It will be of great value in problems of surgical interest. It is of value in locating gastric lesions and at times establishing their nature; for instance, in determining the presence of multiple ulcers, as has occurred several times in my experience (Fig. 5). It is of great use in establishing the patency of a gastro-enterostomy opening (Fig. 17) of the pylorus after surgical treatment, or of the condition of the stomach after resection. It is of aid in locating points of intestinal obstruction and of determining their nature. The Roentgen ray should limit the number of useless exploratory laparotomies in gastric cancer in which the stomach is extensively involved, as it gives valuable information regarding the operability.

CONCLUSIONS

With considerable hesitancy I shall offer certain conclusions. The subject is new and undeveloped. There is a large amount of careful work necessary, anatomic, physiologic and clinical, before its true value can be established. I realize that our knowledge of to-day is fragmentary and will be in part the ignorance of to-morrow.

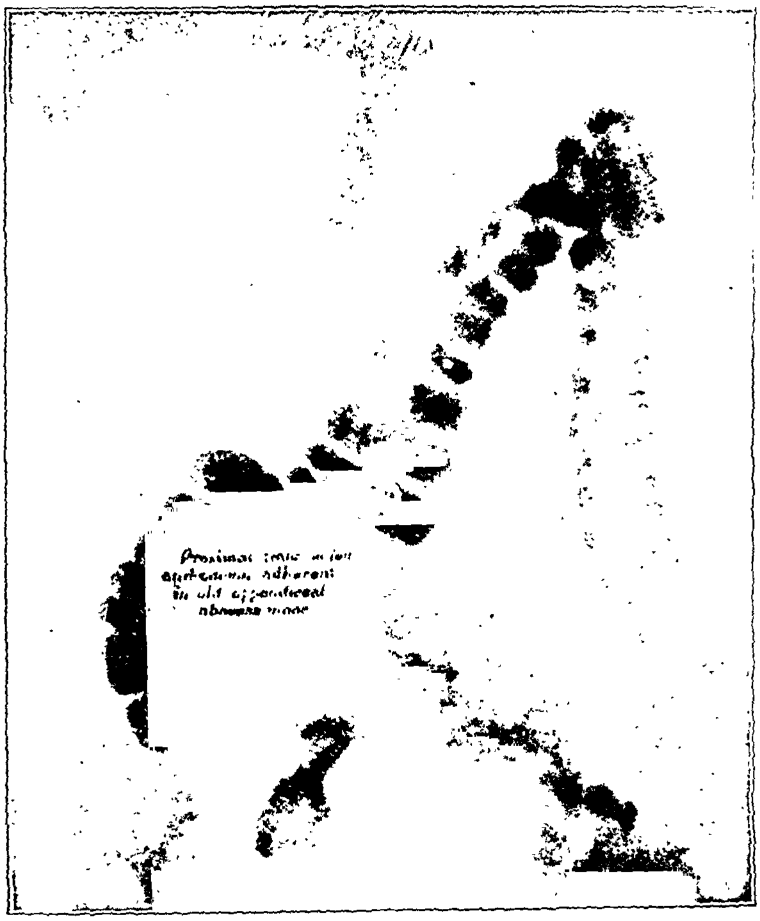

Fig. 18.—Roentgenogram showing cecum and proximal transverse colon adherent in an old appendiceal abscess mass; palpable tumor corresponding to such.

I believe gastro-intestinal roentgenoscopy of great value. Never previously in the history of medicine has a means of physical examination of so great possibilities been so suddenly developed. I should rank it only secondary to the anamnesis in the diagnosis of non-acute gastro-intestinal disease.

The method can be of greatest worth only if correlated with the clinical findings. To estimate its value alone is decidedly interesting and furnishes a check to overenthusiasm but does not indicate its true efficiency. Roentgenoscopic evidence if unsupported by clinical findings must be overpoweringly suggestive to gain recognition. This means that, at present at least, the medium can be most effective only if used conjointly by clinician and roentgenologist, and if both realize that clinical training is the essential in the correct interpretation of Roentgen-ray findings. Regarding the question of the relative value of fluoroscope and plate in gastro-intestinal roentgenoscopy, I believe that the two used conjointly more than double the value of either alone; but of the two, that the fluoroscope is of decidedly greater worth.

The need for conservatism in the interpretation of Roentgen-ray gastro-intestinal findings is very great; the personal equation is unavoidably a considerable one. Deductions should be controlled by operation or postmortem, and in conditions from whose nature this is not possible, by irrefutable clinical evidence.

Wall Building.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. JANEWAY, SATTERLEE AND MILLS

Dr. Chevalier Jackson, Pittsburgh: It would be idle to say that gastroscopy is easy to any one except the skilled esophagogastroscopist. The difficulties can be classed under two heads: first, the instrumental difficulties; second, the technical difficulties. The instrumental difficulties have been practically overcome by the work of Dr. Janeway whose gastroscope accomplishes gastroscopy in a practical manner. On the two different occasions I obtained a most beautiful view of the stomach through this instrument. The respiratory movements, the transmitted pulsatory movements and the various reflex contractions keep the gastroscopic field constantly shifting; but the man who studies the stomach in a careful way gets practical views of the interior and valuable clinical findings. The important point, however, is that the Janeway gastroscope is a practical instrument. The need now is for endoscopists who will use it. In order to overcome the technical difficulties of gastroscopy, the gastroscopist must be a mechanician. He does not need to be able to build a gastroscope, but he must be able to manage it. I know of a man who tried three different times, by esophagoscopic methods, with general anesthesia each time, to get a coin out of the esophagus near the upper orifice. Dr. Ellen J. Patterson took out that coin in a fraction of a minute without any anesthesia, general or local. The physician asked where he could get the instruments, and what they cost. He never thought of asking where he might get a few lessons on esophagogastroscopy. He thought that it was all in the instrument and that if he had had a better instrumental equipment his success would have been easy.

The second class of technical difficulties concerns the introduction of the instrument. While acquiring technical skill the operator tears up the mucosa of the pharynx, though not that of the esophagus or stomach. In regard to the results of gastroscopy: In preparing statistics for the International Medical Congress, I collected almost one thousand cases, out of which the mortality was practically nil; the various tints of the normal gastric mucosa have been discovered; diagnoses of various diseases have been made, including gastroptosis, gastrectasia, chronic gastritis, superficial erosions, round ulcer, indurated ulcer, carcinoma of the cardia, pyloris, greater curvature, lesser curvature and gastric syphilis.

I wish to ask Dr. Mills if he does not think it would be wise in mentioning cardiospasm, to classify it into hiatal esophagismus, abdominal esophagismus and cardial esophagismus. The latter, in my experience, has been exceedingly rare.

Dr. John W. Draper, New York: I have watched the development of Dr. Satterlee's and Dr. LeWald's work in regard to the water-trap stomach. It seems to me that it is conservative to look on it as a morphologic entity. You are, of course, familiar with the variations in the morphology of the stomach, as studied by Professor Kerr of Cornell University. He photographed 100 stomachs immediately after death and found that the variation was much greater than in some of those which have been shown here. Nevertheless, it does seem to me, from careful observation of this work, that the water-trap stomach is different from the ordinary dilated stomach.

One can be pardoned for believing that the surmise is correct, which Dr. LeWald suggested to me, that the origin of the thing is somewhat similar, perhaps to the origin of inguinal hernia; that it is a congenital defect, but one which is potential, and not kinetic, until some trauma occurs. My interest has been centered in the cause of the symptoms. These stomachs give symptoms when they have residue. We do not believe that the residue itself causes the symptoms; that is, we do not believe that they are caused by the decomposition of the food, or the material that is put into the stomach at all; possibly that is a small factor: but we believe that the main factor is, in a measure, analogous to the condition which obtains after partial or complete intestinal obstruction. Perhaps that condition itself is explained by an interference with the enzyme interchange in the intestine

The improvement is extraordinary, after the water-trap stomach has been suspended, and the constipation stops at once. From the point of view of physiologic surgery I have been particularly interested in the cause of the cessation of the constipation. We know that water is vicariously absorbed by the stomach in partial or complete intestinal obstruction. It may be, therefore, that after the stomach is raised and allowed to empty in the normal period, there is less tendency to absorption of the fluids, and that, therefore, the colon gets more nearly its normal share. The other factor, however, we believe to be more patent, namely, that the activating enzymes and hormones, productive of peristalsis, are allowed to take their normal course through the canal.

Dr. L. G. Cole, New York: I have seen Dr. Janeway make this examination on several occasions. The ease with which it is accomplished is surprising, and the patient suffers less discomfort than is caused by the ordinary cystoscopic examination and ureteral catheterization. It is remarkable how perfectly this definite method of viewing the stomach dovetails with the examination of the stomach by means of the Roentgen ray. If there is a weak place in the radiographic diagnosis of gastro-intestinal lesions, it concerns the cardiac end of the stomach. The lumen of this portion of the stomach is large and the peristaltic contractions broad, so that any obstruction to their passage is a defect not readily observed. Dr. Janeway's examination of this region is a complete supplement to the careful radiographic examination, and the two examinations combined offer a method of diagnosing gastro-intestinal lesions which excels all other methods.

Dr. M. L. Graves, Galveston, Tex.: I was impressed with one of the conclusions that Dr. Mills drew, and that is, that great conservatism is necessary in interpreting these results. If those of you who are attempting to make diagnoses of gastro-intestinal conditions will follow up your gastric analyses and your radiographic pictures with exposures of stomachs in cases in which diagnosis of gastroptosis has been made by the surgeon, you will often receive a shock when the abdomen is opened. These patients present a symptom-complex similar to neurasthenia; and 80 or 90 per cent. of them are women. They are anemic, with between three and four million blood-cells, a proportional reduction of hemoglobin and a number of reflex nervous symptoms. In making these examinations I frequently distend the stomach with air, and often find the lesser curvature at or below the umbilicus and the greater curvature down toward the pelvic brim.

Then I subsequently refer these patients to the Roentgen-ray department, this particular form of gastroptosis, with an apparently dislocated stomach is at times shown, and then if the patient is operated on the stomach may not be found in the indicated location at all. The greater curvature is found at about the level of the umbilicus, perhaps just above. It is easy, in cases of chronic ulcers with adhesions or with marked obstruction to the outflow from the stomach, to show a dilated stomach or a gastroptotic stomach associated with dilatation; but these cases with the neurasthenic symptom-complex are frequently misleading. Most of the patients in whom water-trap stomachs are diagnosed will be found to have a pyloric or a duodenal fixation. These cases are rather easily diagnosed by roentgenoscopy.

Dr. Fenton B. Turck, New York: The problem brought out to-day was largely that of the congenital character of many of these dilatations of the stomach. We have here not a mere disturbance produced by some anatomic deformity, but rather some disturbance of the musculature of the stomach.

By means of experiments on dogs I succeeded in producing these identical conditions of fatigue of the muscular wall, both acute and chronic. Acute fatigue was produced by placing the animal under anesthesia and distending the stomach for four or five hours, until complete dilatation was observed. We then made sections of the gastric wall and found evidences of Zenker's degeneration of fatigue. We then carried on experiments looking to the production of chronic fatigue by feeding the animals with extracts of beef and decidual bacteria, dilating the stomach by forced feeding and finally obtaining dilatation with retention, and also found in the muscle walls evidences of Zenker's degeneration of fatigue. This series of experiments I have already published.

Clinical study demonstrates that some individuals are slow to recover from fatigue of the gastric muscles. This probably accounts for most of the symptoms in this class of cases; and the evidence shows that treatment should be along the lines of rest and exercise. The rest method must include suitable diet. We find that many patients, even after operation, fail to recover permanently, in that they have a return of this symptom, and that, therefore, in addition to the purely mechanical treatment of these cases, some other method must be devised, either making operation unnecessary or as an adjunct to operation.

The method followed in our clinic is first to withdraw all food for from forty-eight to seventy-two hours; then to give food slowly at long intervals, increasing the amount and shortening the intervals gradually until finally these patients are given each day two meals of a quality suitable to pass readily through the pylorus. The food should be of such a quality that its resultant assists peristalsis and passes readily through the colon. We found many cases which were aggravated by retention of contents in the colon, toxins being produced which acted injuriously on the musculature. Hygienic treatment in addition is applied to the colon and at the same time colonic lavage, with pneumatic gymnastics of the colon (wave movements of a column of air, produced within the colon by use of a Politzer bulb); if these combined local and general treatments are simultaneously carried out, it usually renders operation unnecessary, except in cases of mechanical obstruction.

It is important to note the line of demarcation between purely mechanical obstructions and those due to weakness of the musculature, for the latter are physiologic and should receive physiologic treatment.

Dr. Henry Janeway, New York: It is necessary to caution against drawing a conclusion in regard to the diagnostic value of gastroscopy which is unsupported by facts. The subject is still in its infancy and is susceptible of much improvement; but this much at least may now be claimed; namely, that we have in gastroscopy a practical means of diagnosing lesions involving the vertical portion of the stomach, especially the cardiac region. This is the region of the stomach in which cancer so long remains latent. I believe that we have in gastroscopy a method of making an absolute and an early diagnosis of cancer in this region. The only question that presents itself is how early will patients complain of their symptoms. It is undoubtedly true, however, that a large majority of them do complain of symptoms early enough to enable us to arrive at a diagnosis while the lesion is still capable of being successfully eradicated.

We owe Dr. Jackson credit for the most important development of gastroscopy. He has not only been the pioneer in this field in America but has also been responsible for definite advances. I have simply followed his lead, and I wish to acknowledge my indebtedness to him for a great deal of assistance and many suggestions.

A very important consideration concerns the amount of discomfort experienced during gastroscopic examinations conducted under local anesthesia and the indications for a general anesthetic. Many gastroscopic examinations, probably 50 per cent., can be conducted under local anesthesia without causing the patient serious discomfort. As a test of the amount of discomfort which such an examination may cause, I have been in the habit of asking a patient whether he really objected to the procedure, and whether he would be willing to undergo it again. If a patient expressed a willingness to undergo another examination, if necessary, or if he stated that he did not have an undue amount of discomfort, it was concluded that the procedure had not been particularly painful. I think that it is going to be possible, however, to utilize intratracheal anesthesia to great advantage in gastroscopy under nitrous oxid.

Dr. G. Reese Satterlee, New York: I was much pleased to-day to see the general trend of speakers toward embryologic influences as a cause of some of these intestinal conditions. I wish to emphasize again the fact that the water-trap stomach is not an enteroptosis. This condition has not received proper consideration or diagnosis. We found in our own experience that many cases were not recognized at all, or were treated for neurasthenia, hypersensitive stomach, ulcer of the stomach, anemia or some other indefinite condition. Dr. Graves has spoken about the gastroptosis cases. We are not discussing the gastroptotic cases. The stomach that we have spoken about is not a gastroptotic stomach, although enteroptosis may coexist, but it is distinctly one due to an embryologic condition with the pyloric arm situated high. We do not want to leave the impression that these cases are all operative. The eighteen operative cases referred to were all followed very carefully with the Roentgen ray and at operation, and in every one of them the lesser curvature was below the umbilicus. Often the pancreas was visible above the lesser curvature.

Dr. Mills brought out one very important point, which also bears out the embryologic theory; he says that there is no normal stomach; that the stomach follows the shape of the body. That is what we find. We think that after a while we are going to be able to diagnose these cases without the Roentgen ray, on account of the long, narrow thorax and the narrow upper part of the abdomen.

One more point, in regard to treatment, showing what can be done in these cases medically. I had one woman with a marked water-trap stomach, a long stomach and a long pyloric arm. She was told to use an abdominal belt, to raise the foot of the bed as high as she could with comfort at night, to take advantage of the night's rest and let the stomach and the colon go up toward their proper place and to lie down on the right side of the body after a meal. I saw her about eight months afterward. She said that she did not have the money to get the belt, but that she had raised the foot of the bed and had rested regularly on her right side after a meal. When she had the symptoms of residue in the stomach which at night gave her pain and nausea, she would turn over on the right side and empty the stomach, and the pain and nausea would cease; thus, by this simple procedure, without any belt, without any operation, she had gained 18 pounds, and was doing well.

Dr. L. T. LeWald, New York: In reference to the question of operation not confirming the findings of the Roentgen-ray examination made one or two days previously, I cannot understand how such a discrepancy could occur, except that I have seen a similar apparent discrepancy when the surgeon operates on a hernia, and the hernia has been reduced by a change of position. The point is simply this: As soon as the patient assumes a horizontal position with the stomach empty it may pass to the upper part of the abdomen, where the surgeon may find it. I have seen instances of this sort in which it could be easily drawn down outside the incision, as far as the symphysis pubis, confirming the Roentgen-ray findings as determined by radiographs taken in the vertical position.

Dr. R. Walter Mills, St. Louis: I am a firm believer in Stiller's views on the subject of the habitus. I believe that its observation constitutes the most important single sign in medicine, considering the universality of its application.

The words enteroptosis, ptosis, atony and dilatation are not used correctly. There should be a perfectly clear and definite understanding with regard to each of these terms, for they mean different conditions.

The findings at operation do not correspond with those found before. One can save himself much difficulty and humiliation by recognizing that this depends chiefly on the fact that owing to general anesthesia, or the opening of the abdomen, tonus is destroyed. I tried to emphasize the point that the stomach is an organ that has this peculiar attribute of tonus, on which under normal conditions in life its form largely depends. The organs of the cadaver, do not possess it; hence, filling the stomach in cadavers gives misleading results; it does not give us the pictures we find in life. That this same tonus is abolished at operation may be suggested by observations which lead us to conclude that the stomach in life must be contracted for one reason, because when empty it has practically no gas content; at operation this is certainly not the case. Each saccule and haustra of the intestines will show its individual gas content, if present, in the plate. I repeat that the most important thing in reaching conclusions is a clarity with regard to such points. At the basis of everything is the ability to individualize and realize that there is no normal type of stomach, but that each normal person has a stomach that fits his body, just as his nose usually fits his face.

THE NEW IMMIGRATION AS IT AFFECTS ORTHOPEDIC SURGERY *

WALLACE BLANCHARD, M.D.
Assistant Clinical Professor in Surgery (Orthopedic), Rush Medical College; Orthopedic Surgeon to The Home for Destitute Crippled Children and to The University Hospital
CHICAGO

A larger number of severe rachitis deformities of the legs have been rapidly corrected by bloodless osteoclasis in Chicago than in any half dozen other cities in the world. The records of the Chicago free orthopedic hospitals and dispensaries show that the new immigrant gives them eight times their normal ratio of rachitic deformities, four times their normal ratio of scoliotic deformities, and twice their normal ratio of tuberculous deformities. Chicago is perhaps the only city in the world having winters of ice and snow that harbors twenty thousand new emigrants from tropical or semitropical countries every year, and very bad rachitic deformities are almost peculiar to the children of recent immigrants from hot to cold climates.

The people from Northern Europe huddle closely. Their children double our tuberculous joint deformities. The German and Russian Jew girls are especially prone to scoliosis. Dr. Peter Roberts, in his book[1] presents a map of the United States, with a line drawn from Atlantic City to Cairo, Ill., and thence to the northwest corner of Minnesota, and says that 80 per cent. of the new immigrants remain north and east of those lines, which mark off only one-sixth the area of the country.

In the year 1911 the highest immigration point was reached with one and a quarter millions. The majority of these people flock to our large cities and settle in the poorer quarters. Their sick and injured fill our free hospitals and dispensaries. Statistics show that in the year 1911 Chicago held eighty-four thousand new immigrants from across the Atlantic Ocean, and it is estimated that one in every five or six comes from a hot country.

The records of three thousand orthopedic cases treated in Chicago hospitals and dispensaries show some interesting points as to the susceptibility of different nationalities to different deformities.

---

* Read in the Section on Orthopedic Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

* Because of lack of space, this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints.

[1] Roberts, Peter: The New Immigration, The Macmillan Co., 1912.

Approximately, one-third of all the cases treated were tuberculous deformities, one-third were rachitic deformities, and about one-third were congenital and acquired other than rachitic, and included the infantile paralysis deformities.

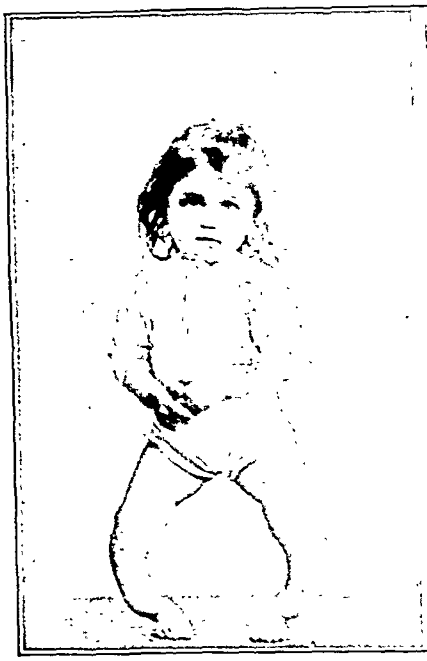

Fig. 1 (Case 1).—Lizzie H., aged 4. Bow-legs. The extreme deformity made locomotion difficult.

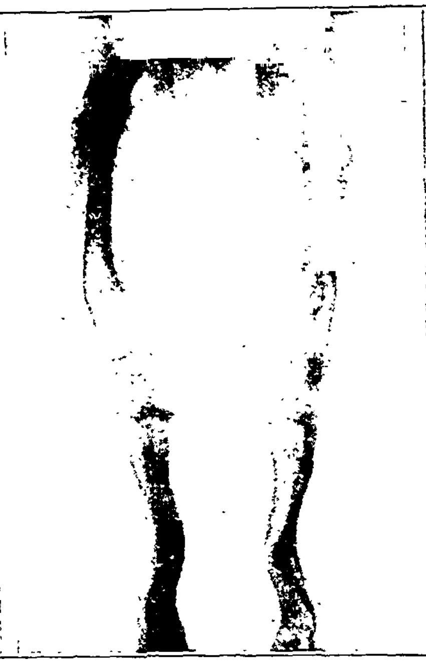

Fig. 2.—Roentgenogram of Case 1 after rapid bloodless osteoclasis and overcorrection at one point only.

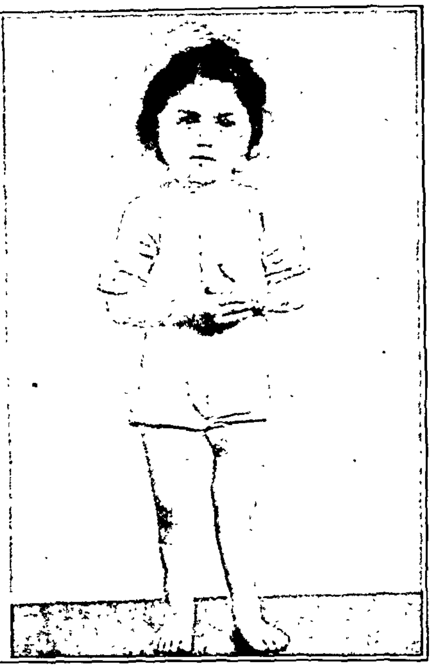

Fig. 3 (Case 1).—Lizzie H., six weeks after osteoclasis, and showing that overcorrection has neutralized the other outbends, producing symmetric legs.

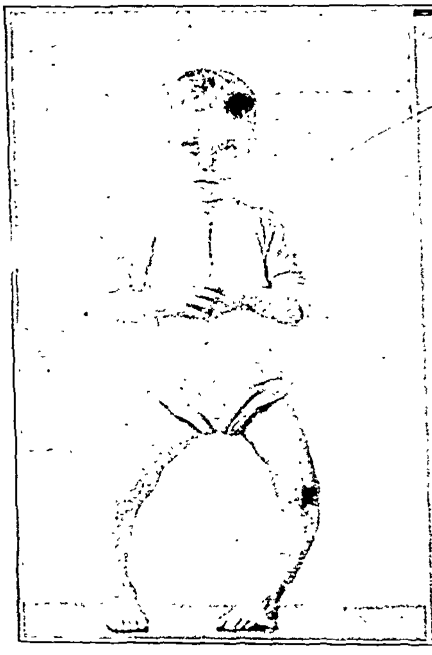

Fig. 4 (Case 2).—Emitt F. Bow-legs, with an inward twist in the shaft of the left tibia and a toeing-in of left foot.

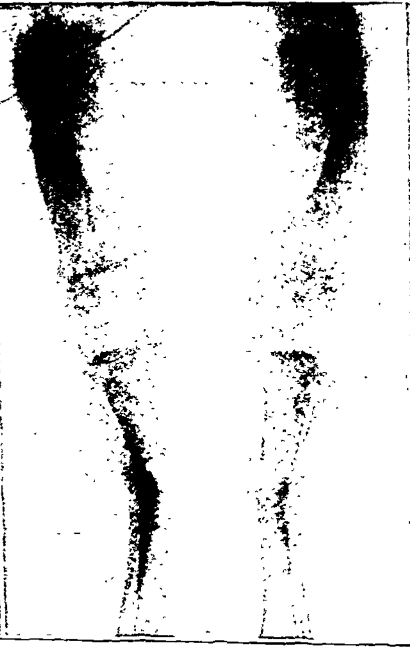

Fig. 5.—Roentgenogram of Case 2 after osteoclasis. Shows overcorrection at apices of deformity bends and rotation out of lower fragment of left tibia.

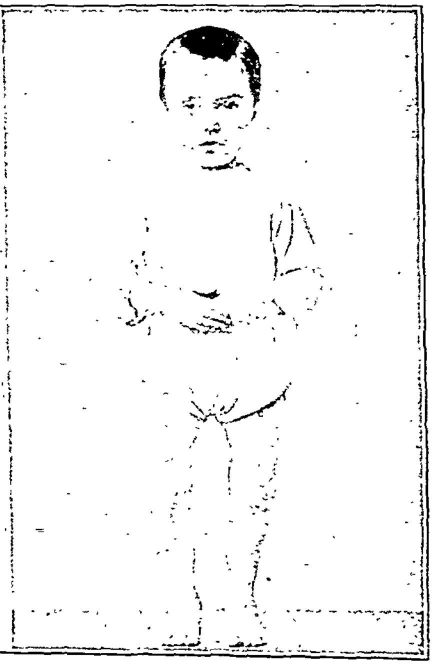

Fig. 6 (Case 2).—Emitt F., six weeks after rapid bloodless osteoclasis, and showing symmetric and useful legs.

My statistical findings may not be exact, but they vary only slightly from those previously presented by Dr. F. C. Test.[2] Of all the patients classed as American, 42 per cent. present tuberculous deformities, while the English, Irish, Scandinavians and Poles show an average of about 48 per cent., and the Germans 35 per cent. Occasional cases of badly twisted rachitic, so-called "grape-vine" legs are seen in the children of colored people from the far South. Notwithstanding the susceptibility of the colored race to pulmonary tuberculosis, only 17 per cent. of joint tuberculosis is shown. The Italians, Greeks, Syrians and other tropical people are almost exempt from tuberculous joint disease, with a showing of only 4 per cent. The Americans lead slightly in congenital deformities, with 12 per cent. The German and Russian Jewish girls develop scoliosis in large numbers. They make up 66 per cent. of all the recorded cases. The most surprising record is given by the Italians, Greeks, Syrians and other tropical people, with 80 per cent. of the rachitic deformities.

---

[2] Test, F. C.: Chicago Med. Recorder, February, 1904.

Why the new immigrant gives us nearly half of our free treated tuberculous joints, two-thirds of our scoliosis and a great majority of our bad rachitic deformities and how the emergency is met will be briefly considered.

The people from northern Europe largely seek work in our clothing and other factories and do piece work at home. These are essentially indoor people, and their children furnish a large share of the cases of tuberculous joint disease. At the Home for Destitute Crippled Children, Chicago, all the acute tuberculous joint cases are treated in an open roof-garden and the convalescent patients are sent to the Country Home, which is largely an open-air structure on a hill, twenty miles from the city. Five years ago the Home had a long line of then incurable chronic sinuses of tuberculous joint disease. My paper[3] on "The Passing of Bismuth Paste," shows that I was the first to report any large number of old sinuses of tuberculous joint disease cured by sinus flooding.[4] The Home cases soon demonstrated the dangers of bismuth and of flooding acute sinuses.

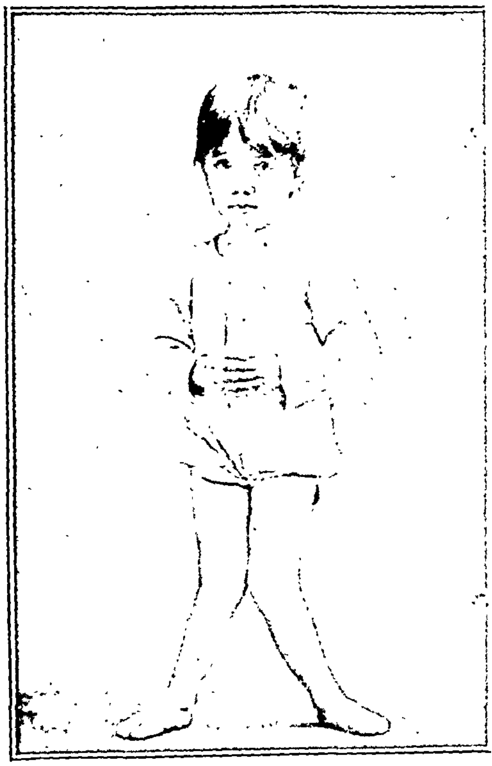

Fig. 7 (Case 3).—Ada S. Knock-knees, so severe as to make locomotion difficult.

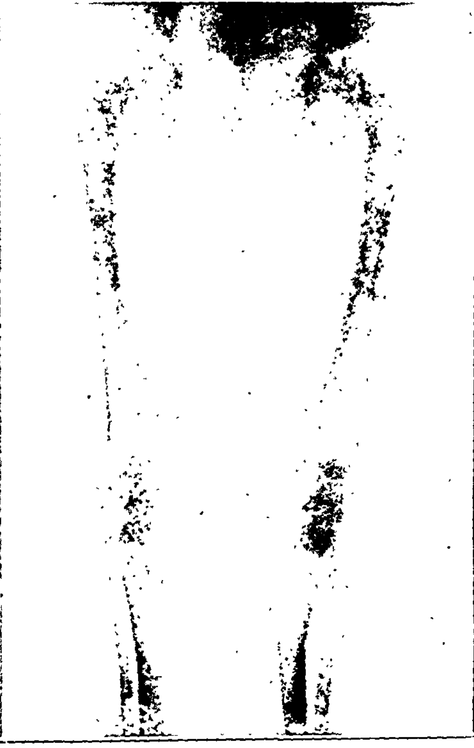

Fig. 8.—Roentgenogram of Case 3 after supracondyloid bloodless osteoclasis and redressment.

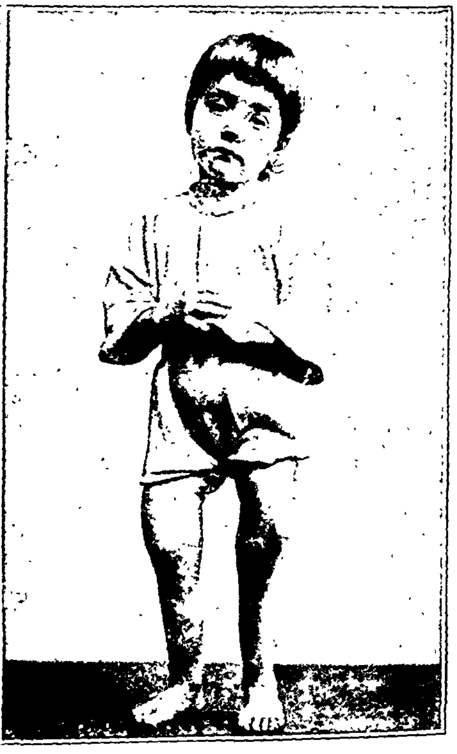

Fig. 9 (Case 3).—Ada S., six weeks after bloodless osteoclasis, showing the knock-knees corrected.

That 66 per cent. of all the cases of scoliosis should be in Jew girls is easily explained. The Jewish mother in a strange land fears to let her young daughter out of sight. The girl sews early and late on shop work, until a vicious posture becomes fixed.

The Abbott treatment for scoliosis has been used for one year and seems to promise comparatively quick and satisfactory results.

A remarkable history is presented by a Syrian colony that was left stranded in Chicago at the close of the World's Fair in 1893. In Palestine they had known nothing of rickets. But a few months of the changed conditions of climate, food and habits had the effect of producing rachitic children. Curiously enough, the children born abroad did not develop rickets. Even babies in arms, but a month old at the time of leaving their old home, escaped deformity. Only the Chicago-born children were attacked, and they suffered so excessively that at one time 80 per cent. had rickets. The rickets was of a severe type, producing bow-legs and knock-knees of great deformity, and also in many cases distortions of the chest, deformed spines, rachitic coxa vara, and curvature of the clavicles and bones of the arms. This condition prevailed for several years. Then, as these people became adapted to the climate and diet of their new home, the rickets began to abate, and in about seven years from its onset it was practically extinct in the colony.

This is a typical rachitic history that is being constantly repeated and amplified.

The unprecedented accumulation of severe rachitic deformities of the legs forced the Chicago orthopedists to get away from the slow and uncertain methods of mechanical devices and repeated osteotomies. So it comes that I am able to report on nearly two thousand bad rachitis bow-legs, knock-knees and anterior bent tibias straightened by rapid osteoclasis; that is, by eight-second bloodless correction in the osteoclast, eight minutes for redressment of the deformity and application of the plaster of Paris, five weeks in plaster, and walking in six weeks on symmetric legs.

The large cities of Europe have nearly stationary inhabitants and none have the conditions that produce bad rachitic deformities. I recently spent six months in the large orthopedic clinics of England, Germany, Austria, Italy and France, and did not see altogether as many bad rachitic deformities as I might have seen at my own clinic in a week.

Professor Adolf Lorenz, of Vienna, strongly favors osteoclasis, though his osteoclast is not to be compared for accuracy with the Grattan. The Grattan osteoclast gives nearly absolute precision in the breaking-point, and the pressure-bar may be moved considerably in either direction from the center without affecting the rule. The term "rapid osteoclasis" is used because osteoclasis that is not rapid is always a failure and brings the osteoclast into disrepute.

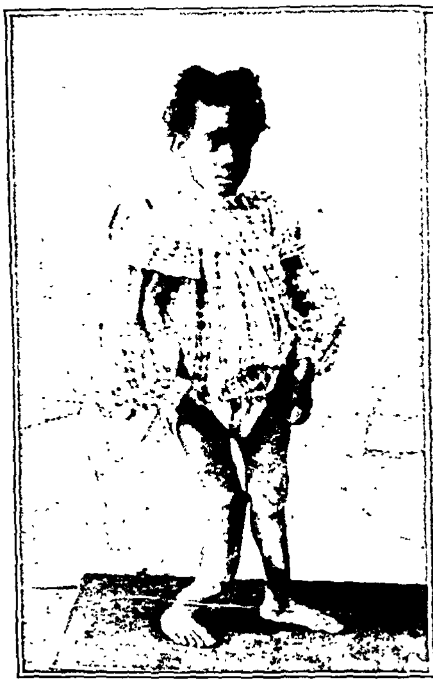

Fig. 10 (Case 5).—Lucy V., with a combination of anterior bent tibias and knock-knees, making "grape-vine legs."

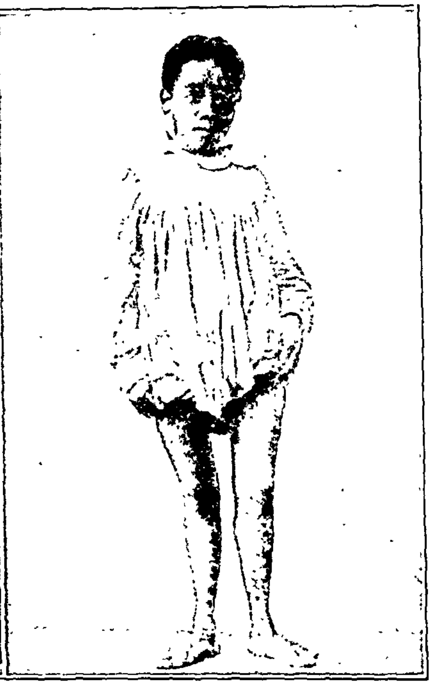

Fig. 11 (Case 5).—Lucy V., after rapid bloodless osteoclasis, showing symmetric legs.

After osteoclasis the bone unites firmly in half the time taken after an osteotomy. Bones bend more or less in the osteoclast before breaking, and the bending contributes toward symmetry of the leg, while osteotomy leaves only an angular correction. I have frequently demonstrated in the correction of bad anterior deformities of the tibia that cuneiform osteotomy on a child 6 to 10 years of age shortens the leg about 1 inch, while osteoclasis of a similar leg lengthens the leg about 1 inch. Two inches difference in height is of great importance to a child already dwarfed by rickets. When the tibia is to be lengthened considerably, the Achilles tendon must be tenotomized as a preliminary step, to allow it to lengthen correspondingly.

In bow-leg with several contributing curves, the apex of the most prominence is usually selected for the operative point and overcorrection is made not only sufficient to correct the curve attacked, but continued sufficiently to neutralize the two minor deformity curves, so that when the plaster of Paris sets it looks like a case of knock-knees. In the same manner, when a supracondyloid osteoclasis has been done for the correction of knock-knees, the legs are held overcorrected and when the plaster has set it looks like bow-legs. An extended experience with rapid osteoclasis has demonstrated better results in six weeks than can be usually obtained in from six months to three years by the older methods.

Osteoclasis should not be done on rachitic bone until it has eburnated. Eburnation represents entirely different characteristics from the slow process of ossification. Normal bones of young children are pliable until ossification, while rachitic bones are friable until eburnation. Eburnated bone is strong, brittle and unyielding. Eburnation may be delayed by disease or insufficient nourishment for weeks or years, but with favoring conditions of fresh air, raw and fatty foods it is quite certain to come, and when it does, it comes suddenly, perhaps in a month, and possibly in a week. Normal bone of a child of 4 years will bend a long way under pressure of the osteoclast before it goes to an osteokampsis or partial fracture, while eburnated bone breaks hard and complete like cast iron. These rules of eburnation cannot be found in either German or English literature, but they are founded on practical experience with several thousand cases.

The mild, non-rachitic bow-legs of small children that are frequently corrected in the course of normal development have nothing in common with the cases reported in this paper.

The emigrant woman has nearly twice as many children as the American-born woman, statistics showing 4.7 against 2.9 per cent. Bad rachitic deformities, tuberculous joints and scoliosis in the young of these new emigrants means a large element of helpless pauperism for the future. Congress has taken steps toward the establishment of a government station in Chicago for the temporary care and protection of immigrants. If the government and the community could be roused to the necessity of caring for the welfare of the immigrant mother for the first year or two in her new home, it would be a great uplift for the future American citizen.

ABSTRACT OF DISCUSSION

Dr. Reginald H. Sayre, New York: There is no question that the changes in the environment, mode of life and diet of a race have a great bearing on their nutrition. Some years ago a number of articles appeared in the medical journals stating that rickets was unknown in Japan and that if we were all to live on rice, as the Japanese do, we should not have rickets. I notice now, however, that it is being discovered that the Japanese have rickets. How much of this is to be attributed to the great strain that has been put on that nation as the result of the war with Russia, and the consequent impoverishment and reduction in the diet of its people, may be a subject for consideration. There is no question that since immigration from Europe to this country has increased the number of cases of rickets has vastly increased. In New York it was a rare thing to find a case of rickets when I first began the practice of medicine, while at the present time deformities of all sorts caused by rickets are frequently encountered.

The Italians and negroes furnish the greatest number of cases of this disease. It seems to me that I saw a great many cases of rickets in Bologna. In fact, the orthopedic hospital there is called the Rachitic Institution, showing that rickets has furnished a large quota of the patients. I understood, however, from Dr. Blanchard's paper that there were, apparently, few cases of that kind there when he went through the institution; when I was there they had rickets of all kinds and descriptions.

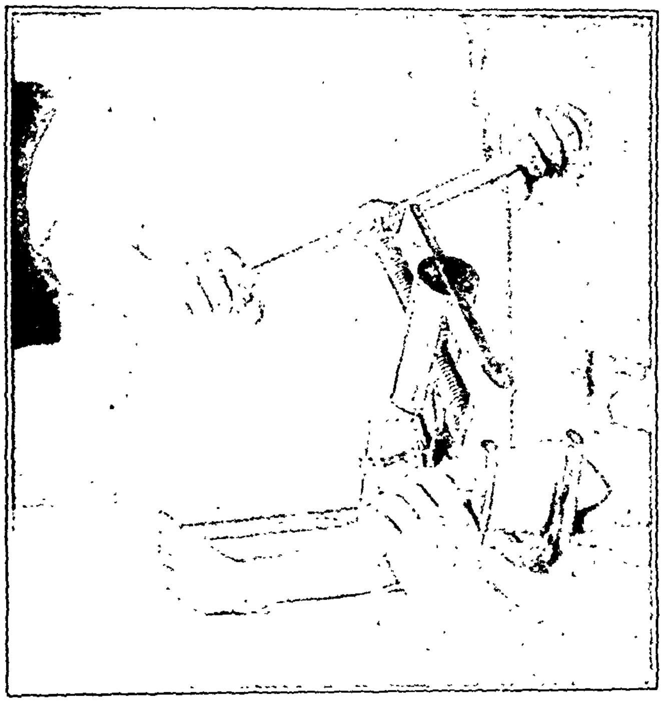

Fig. 13.—The Grattan osteoclast in position to fracture the femur close to the condyles for the correction of knock-knee.

I agree with Dr. Blanchard that the Grattan instrument is a useful osteoclast. I do not understand, however, what he means by "rapid osteoclasis," because I think that, if you exert the force for more than a short time you will damage and lacerate the tissues extensively. All the bone-breaking machines with which I am familiar are based on the principle of a rapidly exerted pressure, rather than a slow, squeezing force, which would certainly do great damage.

In working close to a joint, I believe that you can do better with an osteotome than with an osteoclast, because it is necessary to get a certain amount of leverage in an osteoclast. It seems to me that it is better to make the correction at the point of the deformity rather than at an intermediate point.

Dr. Wallace Blanchard, Chicago: I have spoken of "rapid osteoclasis" in this paper because in my earlier observation of work done with the osteoclast, I found that the pressure was exerted slowly and that the instrument did a great deal of damage simply for that reason. Therefore, I always want to make a point of the fact that eight seconds is the longest time that pressure with an osteoclast should be exerted.

LOCAL AND SPINAL ANESTHESIA IN GYNECOLOGY AND OBSTETRICS *

GEORGE GELLHORN, M.D.
ST. LOUIS

That there is in surgery a field for anesthesias other than by way of the ordinary ether drop-method is so indisputable a premise that I need not waste the few moments at my disposal with argumentation. Suffice it to say that there are no statistics in existence which give a true picture of the alleged harmlessness of the open ether-inhalation narcosis. The exact number of fatalities due to ether will never be known, nor has the rôle of ether in the causation of postoperative complications which endanger life and health of the patients ever been exhaustively considered. Few men have the courage to publish their failures, and the medical journals, as Sellheim remarks, "serve as a medium for recounting accidental success rather than the reverse."

Of the large number of new modes of anesthesia and modifications of old ones, gynecology has been particularly benefited by the two methods which I wish to discuss more in detail—local and spinal anesthesia.

We know both from clinical observations and anatomic researches that the cervix uteri is but meagerly supplied with sensory nerve-endings. Scarifications of the vaginal portions or excisions of small pieces for microscopic examination can usually be done without causing any pain. Under these circumstances it seems to be somewhat out of proportion to employ the heavy artillery of an ether-inhalation narcosis when the injection into the cervix of a small quantity of cocain, novocain, alypin or other drugs will produce an analgesia sufficient for the performance of most of the minor gynecologic operations on the uterus. There is, of course, the objection that the patient retains her consciousness and may therefore suffer a psychic trauma. This objection is largely theoretical. It is undoubtedly a difficult matter to break away from long-established habits. If local and spinal anesthesia—for the same objection has been raised against the latter method and may as well be anticipated here—if, I repeat, local and spinal anesthesia had by chance been discovered earlier than ether narcosis, we may well assume that most of us would look on a state of unconsciousness as a disquieting and questionable innovation.

We must further bear in mind that, though the patient is conscious during local or spinal anesthesia, her sensibilities are not nearly so acute as those of the operator or the audience. Any anesthesia should begin at least a day prior to the operation. Excessively nervous patients should receive bromids, valerian or other sedatives as soon as they enter the hospital. Veronal should be given on the evening preceding the operation to insure sound sleep, and hypodermic injection of morphin-atropin, morphin-scopolamin, or the like, should be administered one-half hour before the time set for operation. Before the patient enters the operating-room, the eyes should be covered with a mask, and the ears filled with cotton saturated with olive-oil. By this preparation the patient's apprehension is dulled, and, if there is no sensation of pain during the operation, there can be no psychic shock. A single trial of these methods will disarm even the most profound skeptic. After all, preparations of

* Because of lack of space, this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints.

* Read in the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

this kind should precede any anesthesia, whether local or general, and it is to the lasting merit of Crile that he has formulated in so precise and scientific a manner the principles of anoci-association toward which many of us have groped empirically.

LOCAL ANESTHESIA

The technic of local anesthesia is simple. In my first operations a solution of cocain, varying in strength from 0.25 to 0.50 per cent. was used. These cases were reported by Dr. J. S. Wolfermann.[1] Warned, however, against the toxicity of the drug by a case of marked idiosyncrasy, I have, for the past months, used novocain exclusively. This drug, combined with a very small quantity of suprarenin, is put up in tablets which are dissolved in normal saline solution so as to represent a concentration of 1.25 per cent. The total amount of solution needed hardly ever exceeds 10 c.c. A strong metal syringe with fine hypodermic needles, of the kind used in dental work, is also required. Both the solution and the syringe are sterilized by boiling.

For injection, I have frequently adopted the technic of Hertzler,[2] who injects small quantities of his solution around the periphery of the cervix and into the broad ligaments blocking the nerves before, or at their entrance into, the cervix proper. In other cases I have simply thrust the entire length of the hypodermic needle into the substance of the cervix at the four points of the compass.

There are no other departures from the usual procedure. The patient is prepared as for any vaginal operation and is then placed in lithotomy position.

The blanching of the cervix due to the action of the suprarenin, which occurs within a minute or two, indicates that analgesia is accomplished and that the operation may commence. All of the operations done in this manner consisted of, or else started with, a curettage. The cervix is slowly dilated with steel dilators, and I have repeatedly been surprised at the ease with which the internal os yielded to the dilatation. After the desired degree of dilatation is obtained, curettage is performed in approved fashion. Occasionally it has been necessary to inject an additional syringeful of the solution into the cervix a little nearer to the mucosa or to insert a narrow strip of gauze saturated wtih the novocain solution into the uterine cavity for about five minutes in order to render the curettage absolutely painless. In the majority of cases, however, these additional precautions are not needed. After the curettage, trachelorrhaphy or amputation of the cervix as indicated in a given case is performed without causing the slightest degree of pain. In like manner a pinhole os may be incised or the Dudley operation for pathologic anteflexion performed. Wound healing was perfect in all cases observed, for it must be remembered that the small amount of fluid used does not produce an infiltration which might interfere with primary union.

When subjected to thorough excochleation patients with inoperable cancer of the uterus suffer rather severely, as a rule, from the combined shock of the inevitable hemorrhage and the ether. These patients do much better under local anesthesia. Novocain has not been satisfactory in these cases. We still employ in this class of cases a cocain solution of 0.5 per cent. In one case in which a 1 per cent. solution of cocain was used, the patient complained of numbness in one leg lasting twenty-four hours. The excochleation is the first step in the acetone treatment, which in itself is quite painless if properly applied.

In a case of vesicovaginal fistula I obtained complete analgesia by injecting a 2 per cent. novocain solution through the urethra into the bladder. The escaping fluid sufficiently anesthetized the edges of the fistula to permit of a painless operation which resulted in permanent cure.

In obstetric work injection of novocain solution into the cervix is an ideal method in cases of incomplete abortion. Reduced by fever and weakened by hemorrhages, these patients often stand an ether narcosis so badly that the cleansing of the uterus of ovular remnants almost assumes the character of a major operation. I prefer the use of very large curets, both sharp and dull, too large to cause perforation; the necessary degree of dilatation of the cervix, softened, as it is, by pregnancy, is exceedingly easy and absolutely painless after injection of novocain. Since resorting to local anesthesia in these cases of abortion, we have observed a much more rapid convalescence, without having to resort to artificial stimulation either by drugs or proctoclysis.

The injection of novocain has been very helpful in cases of induction of labor by means of bags because the necessary dilatation could be secured without any discomfort. Further experiments will have to show whether or not the painfulness of the first stage of labor can be reduced by this method.

Summarizing, then, I may say that by the injection of novocain into the cervix it is possible to perform a number of minor gynecologic operations without danger and discomfort to the patient, and that in obstetric practice the proper treatment of incomplete abortion has been considerably improved by the use of local anesthesia. This method also offers a promising outlook for the management of cases at or near full term.

SPINAL ANESTHESIA

Spinal anesthesia is, at present, passing through a renaissance in the very country which gave it its birth. Not until sixteen years after Corning of New York had discovered spinal anesthesia, and only after Bier of Berlin had independently discovered the same method and Tuffier of Paris had demonstrated its wide applicability before the International Congress in 1900, was the new method adopted in this country, and our medical literature of twelve years ago reflects the wave of enthusiasm that had spread through most of our large surgical amphitheaters. Disappointments, however, which usually travel in the wake of a novel method used too enthusiastically and indiscriminately during its infancy, brought about an inevitable reaction, and spinal anesthesia was denounced as unreliable and dangerous with the same vehemence with which it had been praised before. The failures and fatalities of Jonnesco, which were so closely watched during his visit to our country, were laid at the door of the method, instead of at the door of that surgeon's personal technic. Then followed silence, and the American literature of the last six or seven years would have been sterile except for the contributions of Morton of San Francisco, who steadfastly clung to his convictions. In the most recent past, however, the papers by Allen,[4] Babcock, Bainbridge and a few others have revived the proposition.

In Germany the majority of the general surgeons rejected spinal anesthesia after Hohmeier and Koenig had collected statistics from 2,400 cases, with a large proportion of deaths and other serious complications. The gynecologists, on the other hand, not only retained the method but also perfected its technic. Sellheim,[5] in 1909, reported one thousand major gynecologic operations under spinal anesthesia with but one death and few disturbances. Kroenig,[6] in 1912, recorded 2,542 spinal anesthesias with no fatality or complication except two asphyxias, which yielded promptly to appropriate treatment. Figures of this kind can no longer be ignored or challenged because of the failures of earlier days. An impartial consideration, therefore, of the value of spinal anesthesia, particularly in our special field, is timely; but we must profit from the past and refrain from bringing discredit on the method by too extreme enthusiasm, and we should carefully weigh its limitations and realize that the success of the new method depends on close attention to even the minutest details of the technic.

[4] Allen, Freeman: Spinal Anesthesia, THE JOURNAL A. M. A., Nov. 23, 1912, p. 1843.

To the younger generation of physicians who have grown up in the use of lumbar puncture the idea of injecting a fluid into the spinal canal is not altogether foreign. The fundamental principle of spinal anesthesia is this: to render analgesic those segments of the spinal cord which supply the innervation of the regions on which we wish to operate. If we inject an anesthetic into the space between the second and third, or the third and fourth, lumbar vertebrae, only the sacral plexus and the lower part of the lumbar plexus are affected. This means for our gynecologic work that, in the main, only the external genitals can be operated on without pain. For laparotomies or for vaginal celiotomies higher spinal segments must be anesthetized. In order to accomplish this object, we must drive the anesthetic within the spinal canal upward from the point of injection. There is a limit to this upward extension, for, if the anesthetic reaches the medulla oblongata, it will paralyze the respiratory center and the patient will cease to breathe. Spinal anesthesia has this danger in common with inhalation narcosis, for in the latter the narcotic agent enters the circulation and may, if pushed too hard, paralyze the centers for the heart and lungs.

We succeed in anesthetizing the spinal segments as required for our purposes and yet avoid affecting the medulla by observing the following precautions:

1. Only a small quantity of a highly diluted anesthetic is used.
2. The specific gravity of the anesthetizing solution must be higher than that of the cerebrospinal fluid so that it may ascend within the latter. This progress is facilitated by a slight upward current in the cerebrospinal fluid which was first demonstrated experimentally by Quincke[7] in 1872.
3. To prevent too rapid an ascent, the fluid must be injected very slowly.
4. For the same reason the patient should remain motionless in sitting posture for at least three minutes after the injection, because Straub and Gauss[8] have shown that within this period of time the greater part of the anesthetic becomes chemically bound to the substance of the spinal cord. Such an affinity between nerve substance and cocain was first observed by Mosso and Franck[9] in 1892.
5. The remainder of the anesthetic is permitted to reach higher parts of the spinal cord by changing the sitting position of the patient into the dorsal position and slowly raising the lower end of the operating-table. If this entire change is made too abruptly, the current within the cerebrospinal fluid will be increased and the anesthetizing solution may be precipitated toward the medulla. Failure to observe this caution accounts for many of the collapses which occurred so often during the experimental stage of the new method.

Some of these precautions may be merely theoretical, but the fact remains that, by observing them, the disastrous complications of former days have practically disappeared in the work of competent observers, and one can only agree with Kroenig when he demands that reports of complications due to spinal anesthesia must hereafter contain all details of the technic employed before they can be admitted to serious consideration.

After these more general remarks, the various steps of the procedure, as I practice it, may be enumerated.

At the appointed hour the patient is placed on the operating-table in a sitting posture bent forward as much as possible, and the lower part of the back is painted with iodin solution. An imaginary line connecting the crests of the iliac cones crosses the fourth spinous process which enables us to quickly locate the desired spot for injection. Many authors prefer the space between the second and third vertebrae; I have usually selected the space between the third and fourth. The spinal cord, as a rule, terminates at the upper end of the second lumbar vertebra; it may, however, extend lower down, usually in children, occasionally in women; and in such an anomaly an injury to the cord itself seems possible. Below the termination of the cord the nerve trunks, as is well known, are arranged in two large strands with a small intervening open space filled with spinal fluid. It is in this free space that we wish to inject the anesthetic. The needle is then inserted immediately below the spinous process and exactly in the median line. The injection through the skin and the strong interspinous ligament is slightly painful, and the patient must be warned to keep her position lest the needle be broken by the pressure of the spinous process during a sudden jerk. Then the needle is pushed in an inward and at the same time slightly upward direction until the arachnoidal sac is entered, which is evidenced by the escape of colorless fluid. Only a few drops of this fluid are permitted to escape. The syringe previously filled with the anesthetizing solution is at once connected with the needle and the solution diluted in the syringe by drawing the cerebrospinal fluid into it. After a preliminary trial with stovain, I now use exclusively 2 c.c. of a 10 per cent. novocain solution which contains 5 drops of a 1:1,000 solution of suprarenin.† The diluted solution, measuring in all 6 or 8 c.c., is then slowly injected into the spinal canal, the needle withdrawn, and the site of injection quickly covered with gauze or cotton and sealed with collodion. The patient remains bent forward three minutes more and is then slowly laid down in the dorsal position. The final disinfection of the abdomen, or in the case of vaginal operation, of the vulva and vagina, is attended to immediately, the lower end of the table is raised slightly and the operation can begin at once.

The way in which spinal anesthesia affects the patient follows a certain order. She first notices that the feet feel heavy and "sleepy." The sense of pain becomes abolished first while the sense of touch as yet persists; then this sense, too, disappears. Gradually the recognition of differences of temperature, tendon reflexes and finally the mobility of the legs is lost. At last the peritoneum loses its sensibility. The patients breathe quietly and regularly and the intestines are not pressed out of the wound. The abdominal walls relax completely so that abdominal retractors can be used without difficulty.

[8] Straub and Gauss: Quoted from Doederlein and Kroenig's Operative Gynaekologie, ed. 3, Leipzig, 1912.

[9] Mosso and Franck: Arch. de physiol., 1892, p. 562.

† I am now injecting, with equally good results, 3 c.c. of a 5 per cent. solution of novocain with suprarenin.

The analgesia lasts, as a rule, from one to one and one-half hours; in some of my cases it has lasted as long as two and one-half hours. The sensibility of the peritoneum is the first to return, the sensibilities of the other structures following in quick succession. The analgesia lasts longest in the region of the external genitals.

Since my report of the first forty operations performed by me in the manner described I have done twenty-three additional operations under spinal anesthesia. In two other cases spinal anesthesia was attempted but not carried out, in one because only blood was drawn, in the other because of too small a quantity of spinal fluid to dilute the novocain solution.

LAPAROTOMIES

14 panhysterectomies for inflammatory disease of the adnexa (pus-tubes; tubo-ovarian abscess).
10 hysterectomies for fibroids.
2 hysterectomies for fibroids and pyosalpinx.
2 radical operations for uterine cancer.
1 operation for ovarian cancer.
1 operation for postoperative hernia.
1 operation for ectopic pregnancy (ruptured).
2 operations for fixed retroflexions with extensive adhesions.
1 operation for fixed retroflexion, tubo-ovarian cysts, hernia, and appendicitis.
1 operation for enormous hydrosalpinx and appendix.
2 operations for appendicitis.

VAGINAL OPERATIONS

5 radical hysterectomies for uterine cancer.
3 hysterectomies for fibroids.
1 vaginal cesarean section for exophthalmic goiter in pregnancy.
1 operation for complete tear in patient with exophthalmic goiter.
1 hysterectomy for prolapse.
1 Watkins-Schauta operation for cystocele.
1 Vineberg operation for retroflexion and cystocele.
1 hysterectomy for fixed retroflexion and tumor in parametrium.

In several of the vaginal cases plastic operations on cervix or perineum were done in addition. The age of the patients ranged between 17 and 64 years. Of these sixty-three operations, analgesia was altogether insufficient in one case, that of a complete tear in a woman with exophthalmic goiter. This happened to be the first case in which I attempted to operate under spinal anesthesia. I used stovain for the first (and last) time, and the solution was apparently too weak. Two years later I performed vaginal cesarean section on the same patient. This time I injected novocain and had a perfect result.

In three other cases the analgesia was imperfect.

In six of the remaining forty-seven cases a few whiffs of ether had to be given; in two cases in the beginning because of great nervous excitement of the patient; in the other four at the end of long and severe operations when the suturing of the abdominal walls was under way.

In all other operations, forty-one in number, there was a complete absence of pain. Now and then I had an assistant give a few drops of alcohol on a mask for the sake of suggestion when the patient did not fall asleep at once, but for the most part the patients were perfectly comfortable and were roused only by questions put to them in a loud voice. They paid little or no attention to any remarks made by the operator or assistants and it is altogether a mistake to speak in whispers or to maintain an unbroken silence. "The best plan," says Allen, "is to act as naturally as possible, assuming that the patient is all right and not disturbing her with questions as to her sensations or lack of them. If the patient is nervous or in a communicative mood it is a good plan to detail some agreeable nurse or assistant to sit by her and act as mental anesthetist."

The symptoms which may arise during anesthesia require particular consideration. The most dreaded complication is that of collapse, which figured so prominently in the earlier publications on spinal anesthesia. I have observed a collapse of this kind in one of my earliest cases, that of a stout and asthmatic woman with nephritis and a flabby heart in whom vaginal hysterectomy was to be performed. In this case, a typical collapse occurred when the patient was brought from the sitting into the dorsal position even before the operation had commenced. An injection of strychnin and the introduction of oxygen quickly revived her, and the operation was successfully and painlessly carried out. In another case, that of a poorly nourished prostitute whose vitality was greatly lowered, air-hunger occurred twice in the course of a tedious operation of almost two hours' duration, but it subsided without any treatment.

Vomiting took place in a large number of cases, usually when the peritoneum was incised. This vomiting varied from simple retching to emesis of copious quantities of fluid, but never persisted.

The behavior of patients during an undisturbed spinal anesthesia differs favorably from that of patients operated on under ether and gives the operator a pleasant feeling of security. After operation, this difference is even more marked. All postoperative phenomena occur, as a rule, in mitigated form, and the resisting power of the organism is not reduced by any late effects that might occur after an inhalation narcosis. The wound pain alone is not materially lessened when once the effect of spinal anesthesia has worn off. It is significant that nurses have repeatedly assured me that these patients are more easily taken care of.

The most annoying sequel to spinal anesthesia used to be an intense and intractable headache lasting for hours or days. I have observed this complication but once, in the case of vaginal hysterectomy for multiple fibroids previously referred to when spinal anesthesia was insufficient and a good deal of ether had to be added. It existed from the third to the ninth day after operation, but finally yielded to hot packs. The comparative freedom from these distressing headaches in my cases may be explained in this way: (1) The instruments for injection are boiled in plain water instead of soda solution; (2) the cerebrospinal fluid is not permitted to escape so that the pressure in the spinal canal is not lowered. Conversely, patients from whom from 6 to 10 c.c. of fluid are taken by lumbar puncture for examination always suffer from severe headaches.

Backache lasting one or two days was noted in five of my cases. In two instances the bed-side notes recorded numbness in the legs, and one patient complained of pain in the feet on the day following the operation. Usually, however, free mobility of the legs is regained within an hour or two after operation.

All these disturbances become insignificant when compared with the great advantages of spinal anesthesia. If we consider the 2,542 cases of Kroenig without a fatality, the one thousand operations of Sellheim with but one death and numerous other large series of cases in literature with an equally low mortality, we may be tempted to conclude that spinal anesthesia should be the method of choice and in practically all major gynecologic operations. As a matter of fact, Doederlein and Kroenig draw just this conclusion. They regard as the chief advantage of spinal anesthesia over inhalation narcosis the fact that in the former we have to deal in the main with a local anesthesia in which the greater part of the poison is deposited around the site of the injection and is thus rendered harmless, while in every inhalation narcosis the poison enters the circulation and produces undesirable toxic effects on the other organs, particularly the heart and lungs. They emphasize further that postoperative cardiac disturbances and pneumonies occur far less frequently after spinal anesthesia than after inhalation narcosis. Patients with bronchial troubles or heart lesions bear a spinal anesthesia better than inhalation narcosis. The latter, it is true, is free from postoperative headaches, but since these do not materially alter the general condition of the patients and do not endanger life, they cannot be considered as an absolute contra-indication to the use of spinal anesthesia. Kyphoscoliosis, on the other hand, and other anomalies of the spinal column contra-indicate spinal anesthesia.

These authors, then, prefer spinal anesthesia over inhalation narcosis in all operations with a high mortality, such as operations for cancer and fibroid; but since there is a certain degree of risk in any laparotomy, they use spinal anesthesia in all abdominal operations in preference to inhalation narcosis.

The list of contra-indications as formulated by other authors, who, in the main, concur with Kroenig and Doederlein, also includes fever of unknown origin, sepsis, lesions of the central nervous system, syphilis, pressure-points along the spinous processes which might indicate abnormal conditions within the arachnoidal sac, such as adhesions or lack of cerebrospinal fluid, arteriosclerosis, hysteria, great nervousness and prejudice against the method.

From my own experience, limited as it is, I feel that syphilis need not exclude the use of spinal anesthesia. A large percentage of the patients operated on in the City Hospital and the Barnard Free Skin and Cancer Hospital presented strongly positive Wassermann reactions, yet had no subsequent disturbance attributable to the injection. The amount of cerebrospinal fluid was, however, so small in three of them that in two instances the attempt to inject the novocain solution was given up. It would be interesting to investigate whether or not syphilis reduces the amount of spinal fluid.

I can also assert that psychoses do not necessarily militate against the success of spinal anesthesia, for in two maniacal patients, inmates of the City Insane Asylum, the result of spinal anesthesia was perfect.

With these contra-indications in mind I have employed spinal anesthesia in all cases in which distinct cardiac or pulmonary lesions rendered inhalation narcosis plainly inadvisable. I have furthermore made use of it in patients whose general condition was so weakened either by sickness or age as to render any operation more or less hazardous and finally in complicated conditions in which a severe and tedious operation could be foreseen. These guiding principles find their expression in the list of operations given before, which comprises but few uncomplicated cases. It can thus be seen that I have put spinal anesthesia to a particularly severe test. Furthermore, the fact that only one-sixth of all the patients operated on were subjected to spinal anesthesia shows that the method has not been used indiscriminately.

The time is not yet ripe to form a definite estimate of a method that has been in practical use for less than thirteen years. Spinal anesthesia is not applicable in all cases, but neither is there any other method of anesthesia that would be universal. It would, indeed, be contrary to all our principles of individualization in medicine if we were to depend on any one mode of subjecting our patients to operation. It is true that in a certain small percentage spinal injection fails to produce the necessary analgesia. Whether this is due to the nature of the anesthetic used, faults of technic or to factors still unknown, the future will show. It may be possible to still further diminish this small percentage. There are also a number of undesirable by-effects which have steadily decreased with growing experience and will perhaps be reduced later to a negligible minimum. All these shortcomings of the method have been dwelt on in the foregoing pages in order to make an accurate presentation of the problem before us. On the other hand, spinal anesthesia presents many undeniable advantages over inhalation narcosis and, taken all in all, seems to offer an element of safety which would add greatly to the achievements of modern surgery, particularly in the field of gynecology. In view, then, of all that has been said of both local and spinal anesthesia, it is permissible to contend that he who rejects these two methods a priori deprives himself and his patients of valuable means to render his operative endeavors still more efficacious.

Metropolitan Building.

SPINAL ANESTHESIA IN GYNECOLOGY, OBSTETRICS AND ABDOMINAL SURGERY *

W. WAYNE BABCOCK, M.D.
Surgeon to the Samaritan Hospital
PHILADELPHIA

In 1885 Dr. J. Leonard Corning[1] of New York published the first article on spinal anesthesia. Not considering it feasible to introduce the solution within the arachnoid, Dr. Corning injected a solution of cocain between the spinous processes in the lower dorsal region of a man and a dog. Although in both instances there were evidences of anesthesia, and although Dr. Corning considered the feasibility of operating under this method, nearly fifteen years elapsed before August Bier at Bonn, Germany, first produced intradural anesthesia. Bier had the experiment made on himself and later injected his assistant, an example of medical heroism that recalls Sir James Y. Simpson's demonstration of the anesthetic value of chloroform. Despite the warning from Bier, the intradural injection was promptly tried in many of the clinics of the world but soon was abandoned from imperfections in the technic and disadvantages attending the use of cocain. In 1902, with the discovery of a series of synthetic alkaloid-like bodies having local analgesic properties, the method was revived and came into larger use. Of these substances

* Because of lack of space, this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints.

[1] Corning, Leonard J.: New York Med. Journal, Oct. 3, 1885.

stovain[2], tropacocain and novocain are at present chiefly employed. Cocain has been discarded.

I have employed spinal anesthesia at the Samaritan Hospital since 1904, and our experience is based on over five thousand operations performed under spinal anesthesia by my associates and myself. Except where indicated, I shall here refer only to a personal experience of something over three thousand operations on the abdomen, pelvis and adjacent parts. As a proportion of the patients were subjected to repeated or multiple operations, the number of patients is less than the number of operations. With a similar technic, and with the position of operator and patient reversed, I myself would have accepted spinal anesthesia; and the method is one that has repeatedly been selected by my medical associates, assistants and nurses for operations on themselves or members of their families. This must be my excuse for a rather extensive employment of spinal anesthesia. Cocain, alypin and eucain lactate were used in a small series of cases, and tropacocain and novocain several hundred times each, but stovain has been chiefly employed. The action of a sufficient dose of each of these substances is so similar that a general description will suffice.

PHYSIOLOGIC ACTION

When a solution of a local anesthetic is introduced within the dura it promptly falls or ascends according as its specific gravity is greater or less than that of the cerebrospinal fluid. Cerebrospinal fluid has perhaps the most constant specific gravity of any of the liquids of the body, and in a study of over a hundred specimens taken from patients of different ages and under different conditions we found that the specific gravity almost invariably ranges between 1.0055 and 1.0065. As the slightest variation in specific gravity causes the substance introduced into the cerebrospinal fluid to rise or fall it is not practicable to prepare anesthetic solutions that will remain stationary when introduced within the dura. It is desirable, therefore, to use solutions either distinctly heavier or lighter than that of the cerebrospinal fluid. As the fluid rises or falls it comes in contact with the motor and sensory nerve roots and arrests their power of conductivity. There follow anesthesia, motor paralysis and sympathetic paralysis in the segments affected. The cord proper surrounded by the pia is only superficially influenced, and the columns within the cord may continue to functionate under spinal anesthesia. The autonomic system is practically uninfluenced. Immediately after the injection the patient usually notices a sense of paresthesia in the feet followed in a very few seconds by complete loss of sensation and almost complete loss of motion. The small muscles of the toes and the ileopsoas muscle group succumb last to the influence. As would be expected, the area of epicritic (pain) loss is much greater than the area of protopathic (touch) loss. If the analgesia is not deep the patient may therefore feel the knife although the incision is not painful. The motor paralysis and loss of motor sense are secondary to the loss of sensation and indicate the full intensity of the action of the drug, the anterior nerve roots being less sensitive to the action of the anesthetic than the posterior roots. Analgesia may be present without complete muscular relaxation, especially if the solution be weak, or a weaker drug like novocain used.

With a sufficient dosage the patient is entirely oblivious of the movement or position of the affected part. The action begins a few seconds after the injection, reaches intensity in fifteen or twenty minutes and then gradually disappears, the total duration of the analgesia varying directly with the dosage, being from fifteen to ninety minutes.

Abdomen.—Under spinal anesthesia the abdominal walls become relaxed, the abdomen more scaphoid. Abdominal breathing is largely abolished. The anal sphincters relax, and the gaseous and liquid content of the large intestine escapes. The intestinal tube contracts and shows active peristalsis. Except in certain forms of mechanical obstruction, ileus is usually promptly relieved by the injection. The influence on the intestinal tract may be explained largely by the release from intestinal inhibition. The vasomotor sympathetic nerves, the source of intestinal inhibition, are blocked, and the stimulating autonomic influence from the vagi and the stimulus from the ganglia of Auerbach are unopposed.

Operative manipulations within the abdomen are greatly facilitated by the relaxed parietes and contracted intestine, and the expulsion of gas and fecal matter before the patient leaves the operating-table is especially helpful in the forms of ileus. The stomach in some degree shares in the peristaltic stimulation. If the upper dorsal segments are involved, nausea is often noticed, due probably to cerebral anemia. The patient may be unable to vomit with the head raised, from paralysis of the abdominal walls. If present, the nausea is usually very transient. It may also result from mental impressions.

Urinary System.—While we have not made careful estimations of the urinary excretion under spinal anesthesia, it is evidently distinctly diminished as a result of lowered blood-pressure. The ureters show periodic peristaltic waves that are increased in frequency by mechanical stimulation. We have not observed incontinence of urine under spinal anesthesia. A slight or moderate degree of priapism is only occasionally observed, evidence that a marked influence on the lumbar cord is inconstant.

Circulation.—Spinal anesthesia is characterized by a fall in the blood-pressure and a slowing of the pulse that are proportionate to the height and intensity of the anesthesia. With involvement of the upper dorsal nerve roots the pulse may drop to 40 or 30 and the blood-pressure to zero at the wrists, while an involvement of only the lower spinal segments may produce only a slight reduction in the pulse-rate and blood-pressure. The action on the circulation begins soon after the motor paralysis reaches its acme or in about fifteen or twenty minutes, and gradually passes off. The influence on the circulation may be explained by the following factors:

1. The pressor influences to the cord are interrupted and there is a vasomotor palsy in the involved segments.
2. The limitation of respiratory movements reduces the normal aspirating influence on the venae cavae, and the right auricle fills slowly and therefore the other cavities of the heart fill slowly.
3. The inhibitory influence of the vagi on the heart continues and is largely unopposed.
4. The powerful normal stimulus to vigorous heart action—the *vis a fronte,* is largely lost with the fall in blood-pressure.

A blood-pressure of zero at the wrist may be harmless if the respirations are well maintained. The hypotonus. however, favors cardiac arrest in certain forms of myocardial disease, as well as in thoracotomy and other operations causing sudden changes in intrathoracic tension. The depression of the heart varies directly as the height of motor paralysis. In aneurysm, threatened decompensation in valvular disease, in the excessive tension of eclampsia, in labor, nephritis and advanced arteriosclerosis the vasorelaxation of spinal anesthesia may be protective. Hemorrhage from divided vessels and from the open uterine sinuses is greatly reduced under spinal anesthesia, while there is no increased tendency to reactionary hemorrhage. No other anesthetic produces such a complete vasomotor relaxation, and for this reason spinal anesthesia should be used with care or avoided in conditions of marked hypotension, while it is indicated in forms of hypertension. During severe shock, spinal anesthesia should not be employed. It accentuates preexisting shock although it prevents to a remarkable degree the production of shock by operative measures carried out under its influence. With most other anesthetics the shock of a prolonged operation is reinforced by the progressive toxemia of the anesthetic. With spinal anesthesia the emergence of the nerve roots from the anesthesia as the operation proceeds usually results in the patient's leaving the operating-table in better condition than he was during the early stages of the operation.

---

[2] Stovain is named in honor of its discoverer, Fourneau, the French selecting as more euphonious the English translation of *fourneau*—a stove.

The best antidote for the fall of blood-pressure is the intravenous injection of physiologic salt solution containing epinephrin. From 2 to 10 minims of epinephrin should be added to each funnel (6 ounces) of the saline solution, the flow being interrupted as soon as the pulse returns to the wrist. The amount of epinephrin to be used depends on the effect produced; in some instances 2 minims is excessive: in others 70 minims are hardly sufficient. For patients in extremis it is wise to fasten the transfusion needle in a vein before starting the operation as complete cessation of the circulation for over seven minutes seems to be incompatible with life. In certain instances cardiac massage, best carried out through the diaphragm, must also be used.

Respiration.—The respiratory movements diminish in amplitude according to the height of paralysis of the respiratory muscles. With paralysis of the lower dorsal segments the respirations become diaphragmatic in type but are without the coordinate movements of the abdominal walls. As the thoracic walls relax the patient sometimes complains of a sense of weight or oppression on the chest. The skin, although pale is usually dry and of fair color. If, however, the fourth cervical segments supplying the phrenics be influenced, although the patient may continue to make ineffectual respiratory movements with the accessory respiratory muscles of the neck, asphyxia rapidly develops and the patient will die unless efficient efforts at artificial respiration be instituted. If a solution of stovain be applied to the floor of the fourth ventricle of a dog the respirations are almost instantly arrested but the animal may eventually recover, provided artificial respiratory movements be continued until the centers emerge from the influence of the drug. A similar condition occurs in the human being in anesthesia of the cervical segments, and one should not hesitate to continue artificial respiration for forty minutes or even longer. The respirations under spinal anesthesia are usually slow, and rather shallow. Their small amplitude is favorable to the performance of abdominal operations. Cyanosis is ominous. Respiratory movements are best gaged by a wisp of cotton fastened to the tip of the patient's nose, and this is the best indicator of the efficiency of artificial respiratory measures. If artificial respiration is necessary it can conveniently be carried out by rhythmic compression of the thorax or by forced artificial respiration. A simple emergency method of forced artificial respiration is by intermittently blowing through a soft rubber hose applied over a tracheotomy tube. Resuscitation by the intratracheal insufflation of Meltzer is less convenient and in my experience, less positive. It is absolutely essential that the upper respiratory passages are kept open.

Uterus.—Uterine contractions continue under the anesthetic, but being without the normal aid of the voluntary expulsive forces, they are, as a rule, inefficient even when supplemented by the associated relaxation of the pelvic outlet. The blood-pressure in the uterine sinuses is greatly reduced. Hemorrhage during delivery or during curettment for miscarriage is distinctly less than that seen under chloroform or ether anesthesia. When emptied, the uterus contracts promptly, and I know of no instance of secondary hemorrhage after delivery.

Skin.—Except with the relaxation of high spinal anesthesia, the surface of the body is pale or of normal color, and dry. The suffusion of the skin, drenching sweats and heat radiation of ether are absent.

It is evident that spinal anesthesia has a different physiologic action than that of any other anesthetic. It is of chief value when its application is based on its peculiar physiologic action and when it is used in conditions that render the employment of other anesthetics dangerous.

PERSONAL EXPERIENCE OF THE AUTHOR

In detail, my personal experience is as follows:

TABLE 1.—OPERATIONS ON THE UPPER ABDOMEN

	No. Cases
Stomach:	
Complete gastrectomy for cancer	3
Partial gastrectomy for cancer	10
Resection for ulcer	7
Occlusion perforated ulcer	18
Gastrostomy	6
Gastro-enterostomy	19
Gastroplication or gastrorrhaphy	14
Exploration for cancer, and miscellaneous	51
	128
Liver, Gall-Bladder and Ducts:	
Cholecystectomy	49
Cholecystostomy	68
Choledochotomy, choledochoduodenostomy	6
Operations on liver for rupture, abscess, tumor hydatid cyst and ptosis	31
Miscellaneous	19
	173
Acute Pancreatitis with Fat Necrosis:	
Cholecystostomy and drainage	5
Spleen:	
Wound	2
Splenectomy for acute leukemia (13½ pounds), massive infarction, Banti's disease	5
Omentum and Mesentery:	
Resection, excision of lymph-nodes, chylous cyst, etc.	19
Total operations on the upper abdomen	332

It is more difficult to produce efficient spinal anesthesia in the upper abdominal segments without depression and the analgesia is associated with certain disadvantages not present when only the lower abdominal segments are involved. The anesthesia usually involves the lower thorax and often reaches the level of the third or fourth rib. This interferes in part with the respiratory movements and increases the fall in blood-pressure, and if sufficiently high may cause nausea and symptoms of shock; while if the analgesia be low, traction on the stomach and manipulations near the diaphragm produce discomfort and nausea. It is desirable in many of these patients, therefore, to produce unconsciousness by the preliminary injection of narcotics, but in the weak and debilitated the use of narcotics increases the danger of respiratory failure. The conjoint use of a small quantity of ether at times is less objectionable. In about 80 per cent. of my cases narcotics have been used and in perhaps 5 or 10 per cent. the action of spinal anesthesia has been supplemented on the operating-table by the use of ether. Usually from ½ to 2 ounces of ether will be sufficient for a fairly prolonged operation.

TABLE 2.—OPERATIONS ON THE LOWER ABDOMEN

	No. Cases
Appendix:	
Catarrhal, chronic or incidental	610
Gangrenous, perforative with abscess or peritonitis	215
Appendicostomy	4
	829
Intestine:	
Resection (from 3 inches to 16½ feet)	21
Suture or occlusion	17
Occlusion of perforated typhoid ulcer	14
Miscellaneous, including colostomy, fecal fistulas, adhesions, bands, kinks, diverticuli, ileus, abscess, separation of adhesions, etc.	77
	129
Herniotomies and Operations on Abdominal Wall:	
Inguinal	365
Femoral	15
Strangulated	29
Incisural, umbilical, ventral	57
Lipectomies (from ½ to 14½ pounds)	30
Miscellaneous operations	6
	502
Total operations on the lower abdomen	1,460

Spinal anesthesia has its chief value in operations involving the segments of the lower abdomen and pelvis. In these regions it is not difficult to produce relatively safe and complete analgesia with muscular relaxation. Particularly is it valuable in acute peritoneal infections as from the appendix. In these patients, beyond the possible passage of a stomach-tube, and the sterilization of the skin, no preoperative preparation is required. If meteorism or inflammatory ileus exists the intestinal tract is usually emptied on the operating-table and the patient returns to bed with a scaphoid abdomen. The muscular relaxation and collapse of the distended bowel enable the surgeon to work with greater facility and less peritoneal exposure, handling or traumatism than under conventional methods of anesthesia. A shorter incision may be made and the anesthetic does not add to the patient's intoxication or interfere with normal elimination.

With one exception, during the past nine years, I have selected spinal anesthesia for all abdominal operations on the toxic, septic or desperately sick, and I have withheld operation only from those who were admitted to the hospital in an unquestioned dying condition. In a few instances I have even given spinal anesthesia to the moribund. One such patient, a man aged about 70, with a perforated typhoid ulcer of twenty-four hours' duration, was brought to the hospital cold, cyanotic and nearly pulseless, and died during the operation. Although in other hopeless cases of peritonitis the patients have withstood the depression of spinal anesthesia, and although the operations have taught valuable but terrible lessons to attending physicians and students, I shall not dispute those who consider it better to permit these unfortunate patients to die under the Ochsner treatment. The lowest mortality I have obtained in operating on the appendix, 1.8 per cent., in a series of 220 consecutive and unselected operations performed promptly after admission to the hospital, irrespective of the degree or duration of any associated peritonitis, has been under spinal anesthesia.

Three patients with apparent mechanical intestinal obstruction of some days' duration, that had resisted many forms of treatment, were relieved by spinal anesthesia alone while the patients were on the operating-table and before the incision was made.

I have had little trouble from postoperative tympany, and recall no operation required for postoperative ileus, and it is evident that postoperative intestinal disturbances are not increased by the use of spinal anesthesia.

TABLE 3.—PELVIC AND VAGINAL OPERATIONS

Abdominal Operations on Pelvic Organs:	No. Cases
Hysterectomy and hysteromyomectomy	61
Myomectomy	8
Ovariotomy	7
Operations on tubes and ovaries	148
Suspension operations	54
Miscellaneous	29
Total	307
Vaginal Operations involving the Peritoneal Cavity:	
Vaginal, hysterectomy	105
Vaginal myomectomy	1
Vaginal ovariotomy	7
Vaginal appendectomy	7
Vaginal resection or removal of tubes and ovaries	57
Vaginal anterorrhaphy	3
Culdesac drainage	57
Miscellaneous	17
Total	254

As with operations on the lower abdomen, operations on the pelvic organs are very conveniently carried out under spinal anesthesias.

Spinal anesthesia should be employed with caution in the neurotic, especially those with pelvic symptoms. Frequently they will attribute all postoperative headaches, backaches or pain in the extremities to the intradural injection. At times, under the advice of solicitous friends or unwise medical advisers they become convinced that a hopeless spinal degeneration is developing. It is fortunate if the patients come under the care of a trained neurologist.

TABLE 4.—OPERATIONS ON THE KIDNEY AND BLADDER

	No. Cases
Kidney:	
Nephro-ureterectomy	2
Nephrectomy	10
Nephrotomy or nephrolithotomy	33
Resection of kidney	3
Decapsulation	29
Nephropexy	20
Ureterotomy	2
Perinephritic abscess drained	4
Separation or transplantation of ureter to appendix, intestine, bladder	4
	107
Operations on the bladder	54
Total operations on kidney and bladder	161

Spinal anesthesia seems to have a special value in certain operations on the kidney and bladder. I have not hesitated to operate on both kidneys simultaneously under spinal anesthesia or to do a nephrolithotomy on the residual kidney after the removal of the opposite organ. In one woman aged about 60 the residual kidney had been opened three times previously for recurrent calculi. In a second case, although the residual kidney had been subjected to repeated operations and drained for eighteen months, the patient later married and successfully passed through several pregnancies. From decapsulation performed under spinal anesthesia on patients with advanced forms of nephritis with or without marked anasarcas, I have observed no untoward effects. The anesthetic seems also of especial value in operations on the bladder, especially in removal or resection for tumor, and for prostatectomy.

TABLE 5.—PLASTIC OPERATIONS, AND OPERATIONS ON RECTUM AND GENITALS

Plastic operations and curettements	287
Operations on rectum and anus	150
Operations on external genitals	106

Spinal anesthesia gives very satisfactory relaxation of the perineal muscles. The relaxation of the anal sphincter facilitates operations on the lower bowel. The anal sphincters are among the last to relax under ether and the first to relax under spinal anesthesia. As in other parts of the body, the lowered blood-pressure reduces the hemorrhage. Retention of urine after perineal and rectal operations seems to occur after spinal anesthesia with about the same incidence as it does after the employment of ether. I do not believe that the intradural injection is a causal factor in this condition. As indicating the innocuousness of repeated intradural injections, one patient has been subjected to spinal anesthesia not less than eleven times for repeated plastic operations for hypospadias without evidence of cord or root injury.

TABLE 6.—OBSTETRIC OPERATIONS

	No. Cases
Version	6
Induced labor	1
Manual extraction of 4 months	1
Dilatation and curettement	214
Forceps deliveries	36
Vaginal drainage for pelvic infection	17
Ectopic pregnancies	16
Cesarean section—ruptured uterus	1
Placenta praevia	8
Podalic version	3
Total	303

For a report of 173 of the cases given in Table 6 I am indebted to Dr. J. C. Applegate, obstetrician to the Samaritan Hospital. Dr. Applegate considered the condition of 60 per cent. of these patients such as to render the use of ether or chloroform undesirable. A number of the patients were exsanguinated. In the case of cesarean section the uterus had ruptured sixteen hours previous to the operation and the fetus was in the abdominal cavity. The patient was brought about 20 miles to the hospital and was pulseless. Although the patient seemed to be moribund when the operation was started, she made a satisfactory recovery. The heart action was maintained during the operation by the intravenous use of epinephrinized salt solution. Dr. Applegate reports no diminution of the uterine contractions, and no post-partum hemorrhage or other ill-effects after spinal anesthesia in his service.

I am also indebted to Dr. William A. Steel of the surgical service of the Samaritan Hospital for 109 of the cases given in Table 6, many of them treated in his private practice under the disadvantages incident to a poor home equipment. Dr. Steel notes that the uterine contractions were not abolished, that hemorrhage was markedly lessened, that the placenta may be expelled spontaneously, and that the after-coming head in breech or version operations must be extracted rapidly or else the lower uterine segment may contract on the neck.

In a personal communication Dr. James P. Marsh of Troy, N. Y., reports four successive and successful cesarean sections for eclampsia. The reduction of blood-pressure and the saving of time render the method of value.

In version and threatened uterine rupture the method may be used. Uterine inertia is probably less frequent after spinal anesthesia than after ether.

The danger of pregnancy to the woman with pulmonary tuberculosis is from the violent physical strain of labor. I am indebted to Dr. H. R. M. Landis for the suggestion that child-bearing may be rendered relatively safe to the tuberculous by an instrumental delivery under spinal anesthesia. In one primipara with a large pulmonary cavity, this method was employed with entire satisfaction. The patient had no labor pains or secondary ill effects, and a living child was easily extracted under spinal anesthesia. In pregnancy associated with serious heart disease the method also enables one to obviate all cardiac strain.

In fourteen of the cases in Table 6 I operated for ectopic pregnancy by a free incision through the vaginal culdesac. The affected tube was grasped, pulled down with the vagina, clamped or ligated and excised. A gauze drain was introduced from the vagina into the pelvis and the patient at once returned to bed. This simple operation requires but little time and was found useful in the "tragic" type of ruptured tubal pregnancy. There was no mortality in this small series. Spinal anesthesia has the advantage in obstetric practice of producing no ill effects on the child. In private obstetric practice, Dr. Steel considers that post-spinal cephalalgia is unusually frequent and severe. At present, however, I am inclined to consider postoperative headache and abducens palsy as evidence of the use of deteriorated or imperfectly sterilized solution. Solutions causing headache should promptly be discarded.

TABLE 7.—SOLUTIONS EMPLOYED IN SPINAL ANESTHESIA

Light Solutions:		
A. Stovain	0.08	gm.
Lactic acid	0.04	c.c.
Absolute alcohol	0.2	c.c.
Distilled water	1.8	c.c.
B. Tropacocain	0.1	gm.
Absolute alcohol	0.2	c.c.
Distilled water	1.8	c.c.
C. Novocain	0.16	gm.
Absolute alcohol	0.2	c.c.
Distilled water	1.8	c.c.
Heavy Solution:		
D. Stovain	0.08	gm.
Lactic acid	0.04	c.c.
Milk-sugar	0.10	gm.
Distilled water, to make	2.	c.c.

These solutions are conveniently kept in ampules, each containing 2 c.c. of solution. They should be prepared under aseptic precautions and sterilized by the intermittent method and at temperatures not above 65 C. (149 F). The dose, for the adult, of each solution, is from 1 to 1.5 c.c., the larger dose being employed only for robust adults. Of these solutions that of stovain is the most powerful anesthetic and motor paralyzant, most toxic, most actively hemolytic, and the strongest protoplasmic poison. If not acidulated it is precipitated by the alkaline cerebrospinal fluid. It gives excellent anesthesia. Tropacocain is somewhat less active as an anesthetic, and is considered by some to have fewer untoward effects. I have found, however, that each anesthetic when in solution may show variations in analgesic power and in toxic action, possibly due to imperfect sterility, to by-products not eliminated in the manufacture, or as a result of the decomposing effects of heat. Novocain is much weaker than stovain, but is not precipitated by cerebrospinal fluid, and even in a 10 per cent. solution is not actively hemolytic. The clinical efficacy and clinical toxicity of novocain I would estimate as about one-half that of stovain. The loss of epicritic sense is less under novocain. At present I employ solution A. Solution D is used in the rarer instances in which it is desired to keep the head elevated during the operation. Solutions extemporized from powders or tablets I have abandoned for fear of infection. Except to alter the specific gravity there is no advantage in adding epinephrin, strychnin, glucose, gelatin or similar substances in the anesthetic solution. The repeated production of spinal anesthesia in the same person is apparently no more harmful than a single injection. My experience indicates that if spinal anesthesia is not properly employed by one possessing sufficient clinical skill, it may have a large mortality. It should not be employed by those who have not developed trustworthy aseptic technic or who have not carefully mastered the physiology of the method.*

CONCLUSIONS

Spinal anesthesia is not a universal anesthetic, although it produces the greatest degree of muscle relaxation with the least protoplasmic disturbance. Even if skilfully administered it is probably more dangerous than a transient and light narcosis under ether or nitrous oxid-oxygen, but safer than a prolonged narcosis with complete relaxation under ether or nitrous oxid-oxygen.

Spinal anesthesia causes an earlier and more marked fall in blood-pressure than other anesthetics, with a slowing and weakening of the heart action, and should therefore be used with caution or avoided in conditions of marked hypotension of the circulatory system.

In certain cases in which alarming symptoms follow the inhalation of ether, spinal anesthesia may be used with success. Spinal anesthesia requires a more highly developed technic and a greater degree of watchful supervision than does the use of ether.

Certain sequelae such as headache and abducens palsy indicate that faulty solutions have been injected; late spinal cord degenerations probably do not occur in man; but various cord and nerve lesions may be simulated in the neurotic or hysteric and attributed to the injection.

In abdominal surgery it may be selected when there is an acute pulmonary, severe cardiac, vascular or renal disease, especially when associated with a high blood-pressure. In conditions of acute peritoneal sepsis it is valuable. Against spastic or paralytic ileus it is a most potent agent and its use will often render operative intervention needless.

In malignant disease and for operations on large tumors, while not free from danger, it is at times safer than ether. It does not eliminate the danger of cardiac failure in operations for uterine fibroids.

In obstetrics it facilitates operative delivery, lessens hemorrhage and reduces cardiac and pulmonary strain. In pulmonary tuberculosis it largely relieves the patient of the great danger of labor, the accentuation of the disease. In heart disease it relieves the patient of any strain on the heart tending to decompensation. For operative delivery, during eclampsia it is especially desirable, giving relaxation and lowered blood-pressure without interference with elimination. In extra-uterine pregnancy it is efficient. Spinal anesthesia is relatively safer in the young and robust than in the enfeebled and toxic.

2033 Walnut Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. GELLHORN AND BABCOCK

Dr. A. E. Hertzler, Kansas City, Mo.: First, I wish to criticize Dr. Gellhorn's method of preparation of the patient. My experience is that the less you say to the patient the better. I should think that plugging the ears with cotton would excite rather than allay apprehension. My practice is to ask the patient whether local or general anesthesia is desired. When local anesthesia is selected I take the patient into my confidence and state the stages of the operation offering the greatest difficulties, and keep her informed as to the progress of the operation. The question of local anesthesia is largely one of industry on the part of the operator. Every operation can be done under local anesthesia if the operator has sufficient industry to carry out the procedure.

I desire to emphasize the point made by Dr. Babcock on the need of differentiation between the kinds of sensation that the patient has. It may be a sensation of touch and the operator may think it is a complaint of pain. Only by keeping in touch with the patient by questioning her can this point be determined. Restlessness on the part of the patient is often due to the operator's elbow resting on the patient's chest in abdominal work, or perhaps to the fact that some instrument is allowed to press on the region of hyperesthesia.

Dr. Fred J. Taussig, St. Louis: The work that is being done in the large clinics abroad and in this country will before long give us the exact indications and contra-indications for spinal anesthesia. Contrary to Dr. Babcock's views, I believe that in certain cases of myocardial disease I have had better results from spinal anesthesia than from any form of inhalation anesthesia. In the field of the radical abdominal operation for uterine cancer spinal anesthesia seems to be especially valuable. Any one who has operated on a considerable number of patients with this disease, doing the complete operation, knows what a severe strain it is on the individual. A very considerable reduction of about 30 per cent. in the primary mortality has been brought about by several operators with large experience, since in all of their operations they used spinal anesthesia in place of a general inhalation anesthesia.

I have encountered numerous failures when I have attempted to use the infiltration anesthesia spoken of by Dr. Gellhorn in a cervix that was still hard, as in cases of dysmenorrhea in multiparas in which dilatation and curettage were indicated. Here my percentage of failures was very great. In cases of recent abortion, however, with retained placental tissue or with hypertrophied endometrium, we can readily substitute infiltration anesthesia for general anesthesia. I have met practically no failures and believe with Dr. Gellhorn that recent abortion cases are much less liable to hemorrhage when such an anesthetic is used than when a general anesthetic is employed.

FURTHER POINTS ON THE STERILITY OF WOMEN *

EDWARD REYNOLDS, M.D.

BOSTON

The treatment of sterility has long been one of the comparative failures of gynecology; and one of the most striking points of the case as I have seen them in practice has been the frequency with which women who have been in fact sterile to husbands who are known to have normal spermatozoa have, nevertheless, been pronounced normal even by practitioners of recognized authority. I have, moreover, seen this repeatedly, even when in my opinion a fully adequate cause for sterility was at once apparent in the genitals and when treatment of this condition resulted in prompt fertility. The frequent occurrence of such failures as these must evidently have a reason, which I believe to be that symptoms of ill health of sufficient degree to demand treatment are always dependent on the existence of gross pathologic conditions which we have all long been trained to perceive, but that sterility, on the other hand, is usually dependent on mere perversions of function which are not readily perceptible anatomically, and can therefore be detected only by observation of their results as shown by an altered performance of the daily physiologic functions of the organs.

---

* For untoward effects see: Babcock, The Danger and Disadvantages of Spinal Anesthesia, Proceedings of American Therapeutic Society, 1913.

* Read in the Section [illegible] ology and Abdominal Surgery of the American [illegible] at the Sixty-Fourth Annual Session, held at [illegible] 1913.

* Because of lack of [illegible] abbreviated in The Journal. The complete [illegible] Transactions of the Section and in the author's reprints.

The use of the terms "gross pathology" and "perverted physiology," though strictly in accordance with modern thought, is so far new in this connection as perhaps to demand a definition of the sense in which they are used. Of course in an ultimate analysis any alteration of function is usually due to a variation in the anatomic state of the organ which performs it, but even important functional variations are sometimes so slight as to be unproductive of anatomic variations which are perceptible by the ordinary clinical observations; hence the distinction between a grossly perceptible lesion and one which can readily be appreciated only by its results seems practically helpful, and the expressions "gross pathology" and "perverted physiology" are used here in this sense.

The perversions of physiology which cause sterility in women may be classified under two heads:

1. Conditions of the mucous membranes of the genital tract which may be either small or great in degree, but which even if small lead to alterations of the secretions of these mucous membranes which are destructive to the continued life of the ova or spermatozoa which have been deposited in them, or which annul the effective motility of the spermatozoon in its efforts to reach the ovum.
2. Conditions in the ovaries which inhibit the formation of the ovum or prevent its release at maturity.

A paper which is limited to twenty minutes can evidently attempt no more than a summary of the main features of a large subject, and as I have recently published a much more extended paper on this subject,[1] I propose here to limit myself to such a brief recapitulation of the points there made as may render intelligible some further considerations which were omitted.

THE SECRETIONS

From the time the spermatozoa are deposited in the vagina and the ovum is released from the follicle to the time of their conjugation their only relation to the woman who is their host is that they live in her secretions. The primary condition for fertility is therefore that these secretions should be sufficiently normal to permit the continued existence of the sexual elements until their conjugation is effected.

The alterations of the secretions which destroy the life of the spermatozoa, or perhaps of the ova, are of two kinds: (1) changes in the secretions due to pathologic conditions of the mucous membrane which secrete them, and (2) mere fermentative or other chemical changes in the secretion poured forth by a normal mucous membrane.[2]

Either class of changes may be present either with or without detectible gross pathology and consequent symptomatology, but in either case the mechanism which produces sterility is the destruction of the spermatozoa or ovum by a hostile secretion, and it is therefore only by close observation of the secretions that we can determine the cause and consequent treatment of a given sterility. Further, when gross pathologies are present they be no more than indirectly unrelated to the sterility; and their treatment, operative or otherwise, has then no effect on the sterility, unless the conditions which cause this are treated concomitantly.

The genital canal may be anatomically distinguished by the character of its epithelium into four sections, the vagina, cervix, uterus and tubes. The secretions of any one or all of these divisions of the canal may be so altered as to be destructive to the spermatozoa, and may be so altered either chemically or mechanically. The secretion of any one of these divisions may be abnormal without prejudice to the secretions which originate above it, but an alteration of an upper secretion almost necessarily implies a similar abnormality of the secretions below it and into which it is discharged. In the management of a given case the conditions of each of these divisions must be observed separately and often from the necessities of the case seriatim; they should consequently be so described; and it further seems conducive to clearness to discuss the conditions of each section first without complicating them by questions of treatment, which may then be taken up by themselves.

The Vagina.—The ideal, normal vaginal secretion is that of the healthy virgin, in whom the vaginal secretion is clear and translucent; barely mucilaginous, and in quantity just sufficient to keep the vagina moist and lubricated, and at the same time to permit of disappearance of the secretion by evaporation as it reaches the surface, without the appearance of moisture in quantity noticeable by the woman.

In the patent vagina, which alone concerns our present subject, the secretion is, however, almost never so absolutely normal as this. The vagina of the virgin may be sterile, but so soon as coitus has become habitual the vaginal secretion always contains bacteria of many kinds, which have normally, however, been decreased in virulence and rendered innocuous to their hostess either by the moderate normal acidity of the secretion or by its other chemical characteristics.

The most common alterations of the vaginal secretion are chemical in the form of overacidity, biologic in the presence of active pus cells, and mechanical in great profuseness. The importance of such hostile conditions of the vaginal secretions is susceptible of experimental demonstration by means of various modifications of normal semen on the field of the microscope and direct observation of the effect of these modifications on the living spermatozoa. The majority of such studies have been concerned with chemical modifications of the semen itself, but there have been in addition a few reports of the effect on the semen of specimens of normal and abnormal vaginal secretions. It has further been occasionally possible to combine the necessary examination of the spermatozoa of the husband with the submission of his spermatozoa to contact with the vaginal secretion in question under the microscope, though from the condition of the case the opportunity of so treating fresh spermatozoa will occur but seldom. I had this opportunity once, and although in that case the vaginal secretion was not the only one affected, the prompt disappearance of motion in the spermatozoa as they came into contact with it was quite strong evidence that the existing alteration of the vaginal secretion was in that case quite enough to have caused sterility by itself.

The importance of the vaginal condition must, however, be estimated differently in the nulliparae who form the great majority of the sterility cases and in the multiparae who occasionally consult us for the so-called one-child sterility. . . . In multiparae with lacerated cervices and consequent eversion of a considerable portion of the cervical mucous membrane, it is easy to demonstrate that such a condition as, for instance, the existence of a hyperacidity of the vaginal secretion, is comparatively unimportant. The reaction of the vaginal walls and of the vaginal surfaces of the cervix may in such cases be shown by test paper to be actively acid, while the same paper applied to the cervical mucous membrane when it is thrown into eversion by a speculum will show a neutral or faintly alkaline reaction. With this surface freely exposed to immediate contact with the spermatozoa during the mechanical distention of the vagina in coitus, and remembering that the deposition of only a few spermatozoa on its surface may be sufficient for fertilization, it becomes evident that with such multiparae the hostile condition of the vaginal secretion is of little importance; on the other hand, in a nullipara with the same excessively acid vaginal secretion, but with a pinhole os, the acid reaction of the vaginal surface of the cervix, extending, as it does, to the very edge of the os, makes the chance of the entrance of the spermatozoon into the safety of the alkaline reaction before contact with the acid vaginal secretion so extremely small as to constitute practical sterility from the condition of the vaginal secretion alone. The same considerations probably apply with equal force to the other possible alterations of the vaginal secretion, though with them the actual demonstration is less easy than with the mere change of reaction.

---

[1] Reynolds, Edward: The Theory and Practice of the Treatment of Sterility in Women, THE JOURNAL A. M. A., Jan. 11, 1913, p. 93.

[2] Such a change may, of course, in time react on the condition of the mucous membrane itself.

The Cervix.—The importance of a differentiation between the condition of the cervix and that of the cavity of the uterine body may seem at first sight doubtful; but the existence of a differentiated cervix and cervical cavity is in its full development peculiar to the human race and forms an element which deserves consideration in all comparisons of the physiology of impregnation as between man and the quadrupeds. . . .

The normal mixed secretion of the uterine and cervical cavities is, as it emerges from the os, clear, limpid, translucent and of about the consistency of the white of an absolutely fresh egg. The normal quantity is just that which is sufficient to keep up a constant but almost imperceptible slow flow from the os. Excessive quantity, cloudiness, turbidity and either a mucopurulent or seropurulent appearance are alterations which usually affect both cavities, that is, both the uterine and cervical. Inspissation and stringiness of a portion of the secretion, while the rest remains abundant and substantially normal, is usually an alteration of the cervical condition alone.

The most common causes of alteration of the cervical secretion alone are retention and consequent inspissation of the secretion behind a pinhole os, in which condition the cervical cavity is frequently considerably dilated, thus forming a retention cavity, hypertrophy of the cervical mucous membrane, often semipolypoid in nature, and localized dilatation of cervical glands, with the resultant escape of small quantities of thick stringy secretion. It is probable that the occurrence of inspissation is usually dependent on contamination of the secretions, at least by some of the bacteria of fermentation.

The Uterine Cavity.—The shape and direction of the cervix and shape and situation of the os are always points of importance, because the extremely common underdevelopment of this portion of the organ usually impose some degree of obstruction to the exit of the uterine secretion, and it is as true in this organ as in other mucous membranes that there can be no complete recovery from chronic inflammation without free drainage. It is only necessary to refer to the experience of the rhinologists in the nose and urologists in the male urethra to recall to your memory the extreme persistence of chronic alterations in secretions behind even partial obstruction. So long as the uterine secretion is thickened, clouded, mucopurulent or seropurulent there will be no pregnancy.[3]

The Fallopian Tubes.—It has not generally been realized that the fallopian tubes have a normal secretion, but they are lined with a mucous membrane and, moreover, with a moist and ciliated epithelium, the cilia of which row toward the uterus; it follows of necessity that there is a tubal secretion in continual drainage through the uterus. We are ignorant of the nature of this secretion, though it is probable that it is clear, limpid and scanty in amount; we do know that when the tube is infected its fimbriated extremity closes by adhesion and that it becomes distended with an altered secretion, the character of which varies with the individual infection.

Repeated observations in the course of abdominal operations made since I have been especially interested in sterility have convinced me that in addition to these gross salpingites with which everybody is familiar there are many minor alterations of the tubes, chronic congestions, often with thickening, which have not led to closure of the fimbriated extremity, though such would probably follow in time. Just as the distinct salpingites usually follow an endometritis, so these minor alterations of the tubes have seemed to me to be always associated with similar conditions in the uterine body, and from results I have inferred that they tend to disappear with the latter under the influence of complete drainage, in connection, of course, with depletion and other minor treatment. Remembering that the tubes are morphologically merely a portion of the uterus it would, moreover, seem that these things must necessarily be so.

It is to be remembered, however, that the tubes are double and it might be supposed that with one tube normal the condition of the other was comparatively unimportant; but we must also remember the principle already laid down that alteration of an upper secretion always implies alteration of all the secretions below it, and in accordance with this principle there is considerable evidence to show that with one tube normal and the other pathologic, the spermatozoa may be prevented from reaching the secretions of the normal tube by inability to pass through the abnormal secretions of the uterine cavity which are perpetuated by the continued existence of the other (diseased) tube above. When the abnormality of the tube is slight the diagnosis of such a one-tube sterility is often difficult, but may usually be established with a fair degree of probability by sufficiently careful examination under anesthesia and a comparison of the results of this examination with the tenderness noted without anesthesia and the probabilities derived from the clinical history. Close study of such cases, however, is well worth while, since after proper treatment of the abnormal condition below and the removal of the diseased tube their prognosis is extremely good.

---

[3] It may be remarked in passing and without entering as yet on the subject of treatment, that for the majority of these conditions the routine expedient of dilatation and curettage is usually totally inefficient to the production of fertility, and the sooner the profession as a whole learns this the better it will be for their patients.

THE OVARIES

The existence of an ovarian infertility has long been accepted as a possible though vague explanation of some otherwise inexplicable sterilities; but descriptions of the actual conditions which produce ovarian infertility and study of the possibilities of remedying it are conspicuously absent from medical literature.

The alterations of the ovaries which are most commonly present in sterility cases are slight to moderate enlargements, caused either by the presence of numerous small to medium-sized retention cysts, or by the presence of unduly large, persistent and frequently cystic corpora lutea.

Multiple retention cysts may be distinguished from the normal presence of one(or very occasionally more than one) mature normal follicle by their persistence, undue size or large number. They are usually accompanied by undue thickness of the capsule and are usually bilateral.[4] They are familiar objects to every abdominal surgeon. They are not usually considered of importance. In the course of a long series of conservative operations on enlarged ovaries for other reasons their relation to sterility had not occurred to me until a review of all my cases of conservative surgery of the ovaries led me to notice the considerable frequency with which this work was followed by pregnancy in women who had previously been sterile for a number of years. Since then I have watched this point in every case in which I have opened the abdomen and have seen but one case of bilateral enlargement of the ovaries by multiple retention cysts in a fertile woman. The addition of the conservative surgery of the ovaries to my armamentarium for the relief of sterility in carefully selected cases naturally succeeded and was at once followed by a marked increase in the list of successes.

The assertion that bilateral enlargement of the ovaries by multiple retention cysts bears a causative relation to sterility is at present incapable of either proof or disproof other than by clinical results, the histologic evidence which I had hoped by this time to be able to bring forward having been interrupted by the accidental destruction of a considerable number of specimens which had been carefully preserved for this purpose. I hope in the future to be able to produce such histologic evidence in proof or disproof of my present belief.

The importance of persistent corpora lutea as a cause of sterility is more easily established. Even the possibility of the existence of a pathologically persistent corpus luteum in the human ovary is a somewhat new suggestion, though scattered reports of such cases have appeared from time to time for many years;[5] but it is a quite common surgical experience in the resection of ovaries to find apparently unduly large, and sometimes even cystic corpora in ovaries, some of which have been known to be enlarged for many months, or even years; and the whole trend of modern study warrants the view which some of the best authorities affirm as positively established that the presence of a corpus in the ovaries inhibits further ovulation. There is, moreover, interesting clinical evidence of their importance. Among my records of sterilities which have been successfully treated I find three cases in which a stationary enlargement of one ovary had been noted from periods of several months and in which the enlargement of the ovary was found at operation to be caused by a large and more or less cystic corpus. I find four other cases in which a similar condition was found at operation but in which the patient had been under observation for but a short time before the operation was undertaken. In each of these seven cases the enlarged and apparently persistent corpus was removed from the ovary and its bed closed over, and in every one of the seven cases the operation was followed by the prompt appearance of pregnancy in a previously sterile woman. Further, a similar though less surgical method of removing the persistent corpus has been classical among veterinary surgeons in the treatment of sterile cows for many years and is stated to be very successful.[6]

The subject of the differential diagnosis between these several forms of moderate enlargement of the ovaries is one which I have been for some time studying and which I hope can yet be rendered probable by the differential symptomatology,. but on which I am not yet ready to speak. It is of practical interest in connection with both of these alterations of the ovaries that they are seldom if ever seen in cases which are wholly free from alterations in the lower portions of the genital tract. I have so far seen no such case. It follows that the routine submission of sterile women to abdominal section without careful, exhaustive study of the other conditions is totally unjustifiable and would result in much unnecessary operating. The case as a whole must be carefully investigated first; even then the propriety of instituting an abdominal operation for sterility alone must rest on the conditions of the individual case. It is probably justifiable only when considerations connected with the health of the patient warrant a section independently, or in carefully selected cases after the lower alterations from the normal have been remedied by treatment without avail, and when the intense desire of the patient and her husband for children renders them fully ready to assent. It should certainly not be attempted for sterility alone by the unskilled operator.

METHODS OF TREATMENT

A complete discussion of the technical details of the treatment which has been found in my experience the most successful in the management of sterility dependent on (*a*) alterations of the secretions, or (*b*) ovarian alteration, would form a complicated subject which would necessarily run into great length; moreover, so much of the choice of detail is as yet necessarily empirical, that it would be difficult to put it on paper in clear form. The general principles which govern it can, however, be so stated. Their application to an individual case must be governed by experience as influenced by study of that case.

Treatment of the Altered Vaginal Secretions.—The alterations of the vaginal secretion are apparently always due to infection, with the exception of profuseness which is usually the result of a general pelvic congestion or of those hyperacidoses which are a part of general constitutional hyperacidosis. Treatment naturally follows along the lines indicated by these three etiologies.

The cause of a pelvic congestion must be ascertained and remedied. . . .

General hyperacidosis demands the appropriate general medical treatment.

The results of infection vary in accordance with the bacteriology from mere fermentations of the secretion up to the gross pathologic conditions. . . .

---

[4] When strictly unilateral, they are probably not necessarily causative of sterility.

[6] Williams, W. L.: Veterinary Obstetrics, Including the *Diseases of Breeding Animals*, Ithaca, *1909.*

The Cervical Secretion.—When the vaginal secretion has been disposed of the condition of the cervix must be investigated. This should be carried out first by simple observation of the character of the cervical secretion, and of its quantity as observed for a considerable length of time through a speculum, and by expression of the retained cervical secretion by compression of the cervix; and next by examination of the shape and dimensions of the cervical cavity with a sound and by hooking out any thickened secretion from along its walls with the sound or wire loop. . . .

The Uterine Secretion.—The only two methods of treatment of the uterine mucous membrane which need be mentioned are curettage and disinfection, and for safety and effectiveness both of these are dependent on the coincident institution of free uterine drainage. No disinfection of the uterine cavity is safe unless it is done in the presence of the complete distention and free drainage which is usually attained only after an operative opening of the canal; it is then harmless. Curettage is usually also necessary whenever the uterine mucous membrane is the seat of definite alterations; but no one who has had the experience of removing uteri which have just been curetted can have failed to be impressed with great skepticism as to the results of curettage as ordinarily performed. When a uterus is so inspected it is surprising to see how much of the mucous membrane has been left untouched even by a very careful curettage, and it is, I believe, usually impossible to perform even an approximately thorough curettage without the use of several curets, or of one which can be adapted to every part of the uterine cavity. . . .

Such permanent free drainage is almost never effected by mere dilatation. It can be established only by careful study of the causes of defective drainage in the individual case and the adoption of appropriate plastic work to remedy its cause. Successful determination of these abnormalities often demands very close study; for instance, careful exploration of the region of the internal os after the cervix has been opened by a discission, with a sound which has had the extreme tip bent to an acute angle, often reveals unexpected angulations of the canal, or the existence of bars or prominences in the mucous membrane on the anterior or posterior wall, or both. These phenomena are quite preventive of free drainage and furnish the best of reasons for the persistence of abnormal secretions, yet they are quite unknown to those who merely practice dilatation of the os. All of these conditions are most frequent when the cervix is in anteflexion and underdeveloped. These conditions may demand bilateral division of the cervix and its subsequent repair, the posterior discission and release of forward fixation of the cervix which I have described,[7] or other plastics, or even operations from above; the choice must be left to the plastic sense of the individual surgeon.

After the performance of any of these plastics the uterus should be curetted and the curettage should usually be supplemented by thorough, deep disinfection of the uterine mucous membrane as a part of the operation, and while the canal is still in acute operative distention and consequently under freer drainage than it will have at any other time.

Tubal Sterilities.—The tubes and ovaries are not appropriate for minor treatment other than as the drainage and disinfection of the uterine cavity may usually be relied on as aids to the subsidence of the minor tubal alterations described before, and as the institution of permanent free drainage from the uterus may often be depended on to relieve the minor abnormalities of both the tubes and ovaries. Both of these organs if directly attacked at all must be attacked by major operations; and as the technic of their reparative surgery is again a subject which must be left to the plastic instinct of the individual operator, which is extensive, and on which I have given my views elsewhere,[8] I shall omit further reference to it here.

At the bottom of the whole subject of treatment lies the principle that even the ovarian infertilities are almost invariably associated with physiologically obstructive conditions in the genital canal, minor or major, and that the patency of a canal is only the patency of its most obstructed point; moreover, it must be remembered that I am speaking here not of that simple phenomenon, mere mechanical patency, but of that much more complicated and delicate matter, the physiologic patency, which permits the passage of a living ovum and of a living and actively motile spermatozoon to their point of conjugation, and finally to the implantation of a fertilized ovum. Perhaps the most important and certainly the most generally overlooked point in the whole subject is that the destruction of this delicate physiologic patency is frequently effected by alterations which are so minute in degree or limited in area as to escape diagnosis under merely routine observation. . . .

Accurate, minutely accurate, diagnosis; the limitation of treatment to the areas affected without unnecessary invasions of normal structures above the affected areas; the attainment of complete drainage by appropriately planned and executed plastic work in combination with deep mechanical or disinfective treatment of the affected areas and of them only; and the recognition and treatment of ovarian infertility, when it exists, are the essential principles in accordance with which all the details must be planned.

The treatment of sterility is frequently operative and as such demands operative skill and readiness to assume a not infrequently considerable operative responsibility; but it also involves a minuteness of diagnosis and a patience in treatment which must be exercised sometimes before operation, sometimes independently of operation, sometimes after operation. These facts in connection with the exquisite balance which is necessary to the continued life of the spermatozoon and ovum within the genitals; to success in their search for each other, and to that conjugation and attachment to the decidua which means fertility, all combine to render this subject an intricate one, and to make its treatment one which is almost a specialty within a specialty; moreover, much more study is needed before its details can be placed within the category of accepted text-book knowledge, but that with patience, intelligence, and minute observation, treatment may be made satisfactory and successful is already assured.

321 Dartmouth Street.

ABSTRACT OF DISCUSSION

Dr. Robert T. Frank, New York: Dr. Reynolds has modified our conception of the factors which enter into the production of sterility largely because he has not limited himself to the usual course of study in this subject. He has not confined his attention to the gross mechanical lesions, but has concentrated his efforts in trying to elucidate the "physiologic perversions," as he happily terms them. Dr. Reynolds apparently lays a great deal of stress on the external secretions of the genital tract. Perhaps he is right. The factors which enter into the production of these sterilities are so complex that it is necessary to divide sterility into several classes. I agree with Dr. Reynolds that gross mechanical lesions play a subsidiary rôle. This is shown by the frequency of conception in the presence of vaginal septa and in the presence of fibroids, some of them obstructing the uterine canal. This is shown by conceptions even in the presence of every obstacle that Nature or art can place in its way. Conception has been reported through a vesicovaginal uterine fistula. In my opinion the condition of disturbed function, on which Dr. Reynolds laid so much stress, is really the factor we must study in order to advance in our treatment of sterility. The uterus is often at fault, but not as was formerly considered, not from an inflammatory lesion or chronic endometritis, for instance. In order that conception may successfully take place it is necessary that the ova grow up, ripen and be expelled and received into the tube. Then the corpus luteum must form in the ruptured follicle. Unless this last has occurred the uterine mucous membrane will not be sensitized for the reception of the ovum. This sensitization is necessary in order that the ovum may take root. The corpus luteum is the factor that produces this reaction. Dr. Reynolds, therefore, justly laid great stress on the persistence of the corpus luteum, because a persistent corpus luteum, among animals, has been shown to cause sterility by preventing further growth of all ova which have attained a good size in the ovary. Unfortunately, I think that in the human being we cannot consider the matter so simple as this, for, were the persistent corpus luteum a regular cause of sterility, these cases should always be accompanied by amenorrhea, which is by no means the case. The problem is therefore extremely complicated. The most necessary thing for us to determine, either through animal experimentation or from human observation, is in what case the condition of sterility is due to the uterus, in what case due to the ovary, and particularly whether or not menstruation and ovulation coincide. In this last matter, which has been so long sought for by gynecologists, lies the crux of the question.

[8] Reynolds, Edward: The Ultimate Results of the Conservative Surgery of the Ovaries, Surg., Gynec. and Obst., March, 1912, p. 255.

Dr. Laura Branson, Iowa City, Iowa: I have long been interested in the subject of sterility of women, particularly in that form dependent on ovarian conditions. I was much pleased to hear Dr. Reynolds point out the possibility of the ovary having much to do with the condition of sterility. There is but little literature on this subject. In an April number of The Journal a report gives the following conclusions from a biologic point of view: (1) In vertebrates, the female possesses all sex qualities; (2) The habitat of these sex qualities in the ovary; (3) These sex qualities are developed by the internal ovarian secretion. The biologic conclusions also point to the fact that the ovum is developed by this internal ovarian secretion and that it inhibits or prohibits the menstrual function. Right along this line, let me say that I am more than pleased at the conservative manner in which surgery of the ovaries is at present conducted, because now while biology and physiology are pointing in the direction of study of the ovaries we shall have material left *in situ* on which to base these investigations and experimentations, whereas a few years ago ovaries were removed which might have been saved to perform the functions for which they were intended.

Dr. Charles S. Bacon, Chicago: There is one feature of this subject which I think may be mentioned—the influence of the corpus luteum in sensitizing the decidua. This might possibly furnish a clue to treatment. One might use the products of the luteal body of animals or the corpus sensitized from the uterus. I have employed it in some instances in which, apparently, I obtained results. This gives us something for further study.

In addition, there is the question, How often do we have, not a very early abortion, but an incomplete nidation, resulting in an abortion? This, of course, is part of the sterility problem, and here also the early abortion may be due to the lack of the corpus luteum secretion. Here, too, possibly there may be some help from the early diagnosis of pregnancy. The diagnosis is most important in women who have irregular menstruation. It is of the utmost importance to determine whether we have to do with early abortion. If the newer methods of diagnosis will help us in this, they will help in solving a practical problem.

Dr. J. H. Jacobson, Toledo, Ohio: We must be certain that there are no mechanical disturbances present before we suspect that the secretions are at fault. In short, we must demonstrate positively that there is a patent genital canal extending from the Graafian follicle to the vulva. If you will recall the anatomy of the fallopian tube, you will remember the differences in structure of the tube at its inner and outer end. The lumen at the outer end of the tube is large and there is comparatively little muscular tissue; at the inner end of the tube there is much wall and practically no lumen. The patency of the inner end of the tube is difficult to determine, and it is this particular part of the genital tract that I believe is often the seat of obstruction, the result of inflammatory changes at this point. For some time past, from specimens removed at operation, we have tried to determine the patency of the uterine end of the fallopian tube. We have found that in most cases in which there has been a previous salpingitis, even though of mild character, we could hardly ever get injected fluid through into the uterine cavity. I feel that in the surgical treatment of sterility this form of obstruction is probably the most important lesion to determine. The operation of hysterotomy, as advocated by Deaver, will find a field of application for this class of patients.

Dr. Edwin Reynolds, Boston: Dr. Jacobson brings out a point. We are dealing with something more than a question of mechanical patency. We are dealing with a question of a very delicate physiologic patency. Just as the strength of a chain is the strength of its weakest link, so the patency of a canal is the patency of its most obstructed portion. Now, the point which I wish especially to drive home, if I can, is that, while it is ridiculous to say that there is anything short of an absolute obstruction which can prevent the passage of the ovum, nevertheless, if there is a relative mechanical obstacle, a lack of mechanical patency, there will be a lack of physiologic patency from the inspissated, thickened and altered secretions behind that mechanical impatency, or partial impatency.

FUNCTIONAL TEST (PHENOLSULPHONEPHTHALEIN) OF THE KIDNEY IN SCARLET FEVER *

M. FISHBEIN, M.D.
CHICAGO

Rowntree and Geraghty[1] in 1910 introduced phenolsulphonephthalein tests as a method of determining the functional ability of the kidney. They found on subcutaneous injection of the dye that in normal persons from 40 to 60 per cent. is excreted after one hour and from 20 to 25 per cent. after two hours. They found that in acute nephritis the activity of the kidneys may fluctuate greatly in twenty-four to forty-eight hours. In parenchymatous nephritis there is a marked decrease in the amount of drug excreted and in chronic interstitial nephritis a low output was found in all cases. Later they[2] showed that the test is of value in that by showing a marked decrease in renal function, it indicates impending uremia when other signs are lacking. They conclude that intramuscular injections are better than subcutaneous. This work has been confirmed by Boyd.[3]

who examined a large series of cases, the test proving of especial value in cardiorenal disease, indicating to what extent impaired renal function was responsible for the symptoms.

Erne,[4] using intramuscular injection, found that from 47 to 68 per cent. of the dye was excreted after one hour, and from 74 to 85 per cent. after two hours. Phenolsulphonephthalein tests in a large series of cases showed a lowered excretion when renal lesions existed. The occurrence of albumin in the urine and the excretion of phenolsulphonephthalein did not run parallel. The severity of the objective and subjective symptoms was in each instance in accord with the indications of the results of the test.

The tests have now been made on many hundred cases and in over forty, at least, post-mortem examinations have confirmed the presence of conditions suggested by the test-results.

In the cases here reported the dye was injected intramuscularly. The bladder was emptied and specimens of urine collected after one hour and after two hours. The colorimeter used was that described by Cabot and Young,[5] which consists of a series of twenty tubes, containing 5, 10, 15, etc., per cent. of the dye.

The following protocols will indicate the results obtained:

REPORT OF CASES

Case 34.—Girl, aged 8; previous illness, measles, pertussis, varicella; developed a quite severe scarlet fever April 12; highest temperature 103.6; fever only four days; severe nonsuppurative adenitis from April 16 to April 27; albuminuria from May 6 to May 25.

TABLE 1.—URINE, CASE 34

Date	Amount, c.c.	Sp. Gr.	Albumin	Reaction	Diacetic Acid	Acetone	Ammonia	Microscopic
4/19	1450	1.002	0	acid	0	0	.7308	0
5/6	....	1.012	++	acid	0	0	.....	0
5/8	1420	1.004	trace	acid	0	0	.1512	0
5/25	1450	1.010	trace	acid	0	0	.4698	0
5/27	....	1.008	0	acid	0	0	.....	0

Phenolsulphonephthalein test, May 22, five weeks after onset: first hour, 38 per cent.; second hour, 18 per cent.; total, 56 per cent.

Case 46.—Man, aged 26; previous illnesses, measles, varicella, typhoid; very mild scarlet fever beginning May 1; fever up to to 102 for three days; no complications; no albuminuria.

TABLE 2.—URINE, CASE 46

Date	Amount c.c.	Sp. Gr.	Albumin	Reaction.	Diacetic Acid	Acetone	Ammonia.	Microscopic
5/23	3100	1.003	0	weak acid	0	0	.7254	0

Phenolsulphonephthalein test, May 22, three weeks after onset: first hour, 35 per cent.; second hour, 18 per cent.; total, 55 per cent.

Case 40.—Man, aged 25; mild scarlet fever beginning April 19; fever up to 102 for eleven days; delirious April 26 to April 29; during delirium patient received spirits of mindererus, ½ ounce every four hours, and enemas of normal salt solution containing 10 grains of sodium bicarbonate every four hours; there was continuous marked improvement.

§ Hyaline, granular and epithelial casts.

Phenolsulphonephthalein tests, May 22, ten days after onset: first hour, 48 per cent.; second hour, 16 per cent.; total, 64 per cent. May 27, two weeks after onset: first hour, 53 per cent.; second hour, 32 per cent.; total, 85 per cent.

Case 95.—Boy, aged 12; previous illnesses, measles pertussis; rather mild scarlet fever beginning June 19; fever up to 102 for twelve days. On July 11, a *trace of albumin* appeared in the urine. On the morning of July 12, a slight puffiness below the eyes was noted. The *patient complained* of severe headache. By evening the whole face *appeared swollen*. The urine was extremely scant. On the morning of the 14th the face and eyes were markedly puffy, headache was severe and the patient vomited. On the 13th one-half ounce of magnesium sulphate was given. On the 14th, an ounce of magnesium sulphate and a hot pack were given. The patient was also given 4 ounces of Fischer's isotonic enema (consisting of 10 gm. of sodium carbonate and 7 gm. of sodium chlorid *in a liter* of water), by the drop method every four hours. The vomiting and headache continued. On the 15th the treatment continued as before. June 16, the patient was given a hot pack morning and evening and the hypertonic enema containing 14 gm. of *sodium chlorid and 16* gm. of sodium carbonate was substituted for the isotonic solution. At 7 a. m. he became comatose and had irregular movements of the hands and legs; on being placed in a hot pack the symptoms abated. At 3 p. m. another attack occurred which was also relieved by hot pack. At this time sodium bicarbonate, 10 grains every four hours and sodium citrate 15 grains every four hours were ordered. From this time on the flow of urine became profuse and as the patient passed on to quick complete recovery the alkaline treatment was gradually discontinued.

59	Very severe	1	*	15	10	25

* Patient died in epileptic attack 7 days after onset. Post mortem there were found passive congestion and cloudy swelling of kidneys. Marked albuminuria throughout time of observation.

CONCLUSIONS

There seems to be a general lowering of the renal function during the *latter stages of scarlet fever.* In nearly all uncomplicated cases examined from the third to the fifth week a total output averaging 55 per cent. was observed as compared with a normal of 65 per cent. to 85 per cent. In the instances of *acute nephritis,* an increased output was observed in two, a lowered output *in one.* In several instances in which headache and nausea *occurred,* although no albumin was found in the urine the test showed a decreased function of the kidney. The practical value of *the test* as an aid in the treatment of this disease in which nephritis is so common a complication is apparent.

RESULTS OBTAINED IN THE NON-SURGICAL TREATMENT OF TUBERCULOSIS OF THE JOINTS*

H. WINNETT ORR, M.D.
LINCOLN, NEB.

The reasons for and against the surgical treatment of joint tuberculosis have been ably *presented and discussed* by many good writers on the subject. Perhaps the whole argument on the operative treatment of joint tuberculosis is as well presented in the recent work of Goldthwait, Painter and Osgood,[1] as anywhere in recent literature. As I interpret their attitude on this question, it is that we are and should be drifting away from the tendency to operate in these cases in adults as well as in children, but that in selected cases operation may still be considered to be admissible for a variety of reasons, five of which are set forth as being worthy of consideration in connection with radical surgical treatment. Of the five all are held to be invalid under most circumstances. With the views set forth by Goldthwait, Painter and Osgood in this work it is my pleasure to agree most heartily. Their conclusions are at the same time scientific and sensible. It is my purpose, however, in this paper to carry their teachings somewhat further and to strengthen their conclusions if possible, by a series of observations, somewhat different from theirs, on my own patients.

It has been some years since I began to be impressed with the fact that patients with joint tuberculosis coming under our observation who had previously been operated on were, as a general thing, much more seriously disabled and that the active stage of their disease was much more prolonged than even the advanced cases in which the patients had not previously resorted to surgery.

My intention is to compare, in patients operated on and those not operated on, the periods of active disease process and the amounts of resultant deformity. I have therefore checked up recently a series of fifty patients of this character, of whom I had satisfactory records for the purpose. I have attempted to determine the actual period in each during which the disease may be said to have been active. In many cases this was of necessity a matter of estimate, but I have tried to be fair and liberal both to those operated on and to those not operated on. The results of this study show a wide margin of advantage for the patients not operated on. In fact, although the information used is somewhat difficult to determine for statistical purposes, the patients not operated on have done so much better than those who were operated on that the tendency of the conclusions is inevitable, even if a measure of inaccuracy in the original figures should exist.

I found, for example, that of all patients operated on before coming under our care at the Nebraska Orthopedic Hospital and in my private practice and all patients not operated on, the patients operated on averaged a period of active disease much more than twice as great. It is difficult to arrive at any very satisfactory conclusions regarding the amount of difference in the resulting deformity, but conclusions based on estimates as fair as I am able to make them indicate that the patients operated on suffer an amount of deformity greater than the patients not operated on, which also approximates 50 per cent. This fairly agrees with my conclusion as to the length of active disease, for active disease over twice the period would naturally mean more bone and joint destruction and correspondingly greater deformity.

---

[1] Goldthwait, J. E.; Painter, C. F., and Osgood, R. B.: *Diseases of the Bones and Joints,* Boston, 1909.

Operation in adults especially is perhaps most frequently invoked as a time-saving expedient. In the patients studied this proved to be a fallacy, as these patients were disabled much longer than the average of patients conservatively treated. Those who did not recover primarily from the surgical operation still thought their treatment practically over, and went or were allowed to go about with the usual result—mixed infection and continued trouble.

There are three or four principal factors which contribute to the bad results which I charge up to surgical interference in these cases: (1) operation on patients who have not been properly selected; (2) operation by inexperienced surgeons under unfavorable conditions, and (3) failure on the part of experienced surgeons who have done good operations to keep the patient under supervision for proper dressings and after-care until recovery is complete. None of these factors except the patient himself is beyond the control of the surgeon, and it is to be borne in mind that the patient who in the early stages of his disease is intolerant of apparatus will also be impatient in the matter of after-care and should be handled accordingly.

All of our experience with bone and joint tuberculosis teaches us that a large percentage of good results may be obtained by conservative treatment when the diagnosis is made early and the treatment carefully carried out. It is hardly necessary to emphasize here the importance and ease of early diagnosis of joint tuberculosis and the simplicity of early treatment. It is unquestionable that careless diagnosis and ignorance on the part of some over-enthusiastic surgeons of the splendid results obtainable by efficient mechanical treatment prompt them to do operations of this kind which might better have been left undone. My own experience has been that equally good results may be obtained even in those patients requiring a minor surgical procedure, even in late cases, when it is combined with careful mechanical treatment and strict surgical after-care.

Some of the literature for the last few years urging radical surgery has done much harm because it has persuaded surgeons to undertake these operations who have neither proper facilities nor suitable surroundings in which to do the kind of surgery these patients then require. It is also true that many good general surgeons, having failed to obtain primary results following these operations, have allowed their patients to drift into less competent hands or even to do their own surgical dressings with the necessarily following mixed infection and chronic sinus.

Patients may recover from a large amount of joint damage under non-surgical treatment. The conclusions from my entire list of patients sufficiently emphasize the point that disability and deformity are much less in the patients not operated on.

In passing it may be well to mention that in this particular series there has been no death in any case in which the patient was not operated on, or in any case in which the patient had the first operation under our care, while there have been three deaths in patients previously operated on.

First National Bank Building.

ABSTRACT OF DISCUSSION

Dr. Leonard W. Ely, Denver: In some parts of the United States, what might be termed the accepted or standard treatment for a tuberculous joint is amputation. I think that Dr. Orr goes a trifle too far in the matter of adult joint tuberculosis. I have never seen a private case of adult joint tuberculosis that I could say was cured by conservative measures. I have seen the disease quiet down, and remain quiet for years; but it would then light up again. I think that possibly the reason for the failures in operations in these cases is a mistaken idea in regard to the object to be accomplished. If an adult joint is opened, scraped and drained, it will almost certainly become infected, and, instead of a comparatively simple disease, a serious condition will result. If we open the joint with the well-defined purpose of destroying it and getting bony union, I do not believe that tuberculosis can exist any longer in that locality.

Dr. Edwin W. Ryerson, Chicago: I agree with Dr. Ely that the cases should be demarcated accurately with regard to the age of the patients. I have yet to see an adult patient with a hip- or knee-joint tuberculosis recover without an operation and with a movable joint, and I have yet to see any case of adult hip-joint tuberculosis recover without operation, with any kind of a joint. The chief thing that struck me about Dr. Orr's roentgenograms was that while the patients had recovered without operation, most of them needed operation badly in order to get rid of the abduction deformity that was present. If an osteotomy after the Gant or Brackett methods had been performed, I think that all of them would have had more useful legs.

Dr. John L. Porter, Chicago: I wish to add my testimony to that already adduced in support of the opinion that tuberculous joints in adults do not do so well as those in children. During an experience of nineteen years I have seen several hundred cases of tuberculosis of the joints in adults; and I have seen few recover by ordinary conservative methods—that is, as completely as a child's joint would. I think that many adult tuberculous joints would recover from the symptoms, and, perhaps, show as good result, if operated on. In other words, I think that the mistake is made in many instances in not operating in the case of an adult, because infection is much more likely to be present in an adult than in a child. In the case of a man who is a wage-earner, for instance, and needs to return to work quickly in order to support a dependent family, I should advise operating, as I should not in the case of a child.

Dr. Emil S. Geist, Minneapolis: I should like to ask Dr. Orr to tell us the end-results in these cases of hip disease. I should also like to ask what he considers a good result, and further, what form of conservative treatment was employed in these cases.

Dr. John Ridlon, Chicago: I am rather surprised to hear the remarks of Dr. Porter and Dr. Ryerson. Their ideas are so different from the views that I hold. When I came to Chicago from New York, twenty-one years ago, I thought that it was true, as I had always been taught, that tuberculosis of the joints in adults did not do nearly so well as tuberculosis of the joints in children, but I soon learned that the contrary was the fact in my patients. I found more tuberculosis of the joints in adults in Chicago than I had found in New York, and I learned that tuberculosis of the joints in adults did better than tuberculosis of the joints in children in Chicago. I supposed that this was the experience also of the other men there; but these doctors have had a large experience in the Cook County Hospital, where they see the worst class of cases and where efficient treatment for more than a few weeks is not possible. I have always believed that an adult should be told the facts about operative treatment, and as to the long period that is likely to be required (three, five or even eight years, perhaps) for a cure by non-operative methods, with the possibility of obtaining a cure in a much shorter time by an operative procedure. The best treatment, however, for a tuberculous ankle or knee, and possibly also a hip, in an adult who is a wage-earner, is certainly an amputation; and I have done one or two amputations in thirty-five years. These patients do get well, but, as Dr. Ely says, you must not take the word of an eminent man, like Murphy or Ridlon, against that of Dr. Ely. You must see the results. I showed to the Central States Interurban Club in Chicago, a few months ago, three patients who had been cured. Since then, I have chanced on two other cases in adults, who had beginning abscesses, and were cured without deformity and without any evidence of their ever having had the disease. My experience is that tuberculosis of the spine is much more serious and is harder to cure in either a child or an adult than is tuberculosis of the hip or knee. I may be wrong in this, but if the spine can get well without operation and without deformity, the hip or knee can, in either the adult or the child.

Dr. Edwin W. Ryerson, Chicago: When I said that I had not seen a tuberculous joint in an adult recover without operation, I meant the joint, and not the tuberculosis. I have seen cases in which tuberculosis of the joint was cured, but not the joint. It all depends on the interpretation of the word "cured." If you mean by this word that the joint has returned to the normal, I have seen no cures in adults, other than the three cases of spinal tuberculosis that Dr. Ridlon showed at the interstate association. If he says that there is motion in these joints, there is.

Dr. Ridlon: I do not know whether there is or not.

Dr. Ryerson: Well, the tuberculosis is cured; but a cure of the tuberculosis in the joint, does not mean the return of that joint to normal. If such an interpretation is accepted, I have never seen a tuberculous joint in an adult cured, either with or without operation.

Dr. John L. Porter, Chicago: I am going to modify what I said a little differently from the way in which Dr. Ryerson modified what he had said. He hedged by saying that he meant cure of the joint, and not cure of the tuberculosis. I will not hedge a particle. I meant the cure of the disease. I said that tuberculosis of the joint in an adult is seldom and possibly never cured. Persons who have had the disease as young adults will sometimes come back when over 30 years old, showing evidences of the disease in the same locality as formerly. I have at present under my care a woman of 50, who had tuberculosis of the spine and, we believed, recovered five years ago; but she came back to me with the same focus, and also another one, four vertebrae lower. I have been impressed with patients who seemed to be cured, but were not, the patients coming back to me later in adult life with a recurrence.

No one, perhaps, has been so close to Dr. Ridlon as I have. I have worked with him and been his assistant. I do not believe that anyone has a higher opinion of Dr. Ridlon's diagnostic ability than I have; but I know that years ago we made more mistakes in diagnosis than we do now, and I think that many of the spines and hips that we treated then and that improved so quickly might not have been tuberculous, even though Dr. Ridlon made that diagnosis.

Dr. John Prentiss Lord, Omaha, Neb.: I have been associated with Dr. Orr in the work in Lincoln, and I have been a general surgeon for twenty-two years and orthopedics has been a part of my work. Inasmuch as the question of operation and non-operation is under discussion, I want to claim a little credit for the non-operative methods in the treatment of hip disease in the Nebraska State Hospital. We were able to announce in the last report that there had been no amputations. About one-third of our cases are tuberculous. Our patients number between 110 and 115 all the time. There has never been a resection in that hospital, and the only surgery that we do is to meet the surgical indications. There is no orthopedist, I believe, who will take exception to that. I have, however, seen orthopedic surgeons who urged, on the wrong side, I thought, that we did not meet the surgical indications as soon as they would in some cases of accumulations of fluid in and about the joints. My practice has been the same as that of the others who have spoken with regard to adult tuberculosis.

Dr. Porter: Do you treat adults there?

Dr. Lord: Occasionally, but not many. They are inconsiderable in number, as a matter of fact. What I say now is in regard to my general experience rather than to my experience in that institution; and that is, that after ordinary methods of treatment have been exhausted in an adult, and he is manifestly losing ground, it has always been my practice to do a resection of the knee, for instance, rather than to allow that man to go on and develop tuberculous osteomyelitis, which would perhaps subsequently necessitate operation. Then, the economic question in the adult is serious. We must do something for these people and enable them to work. We cannot treat them for from three to eight years, as we can a child. It is another proposition entirely.

Dr. Arthur Steindler, Des Moines, Iowa: I wish to mention a case of apparently complete recovery from Pott's disease in a young woman who was first examined by me three years ago. She had all the clinical symptoms of tuberculous spine, the boss of the gibbosity being the eighth dorsal vertebra. Reexamined three years later she had to all appearances a normal spine with no deformity and no restriction of motion. Bearing out what Dr. Porter has said regarding the latent intervals of hip disease in adults, I remember a case of reappearance of tuberculous hip trouble with all clinical symptoms not less than thirty years after the primary infection. Three cases out of my last series of cases of hip disease, treated by Lorenz' method of fixation and weight-bearing have healed with normal range of motion, but as these cases have been exceptionally mild and the bone involvement limited, I should hesitate in basing any preference of Lorenz' method on them.

Dr. J. D. Griffith, Kansas City, Mo.: I have had several cases of tuberculous hips in grown persons. Those cases that have recurred, I have made up my mind, were tuberculous; while those that did not recur, were not tuberculous. I probably made a mistake in diagnosis.

Dr. Fred H. Albee, New York: A point that has not been mentioned should, I think, be emphasized strongly, and that is, what the pathologic condition is. When a tuberculous joint has become cured relapse is extremely rare if it is a bony fixation; but if it is a fibrous union, a fibrous encapsulation of the tubercle bacillus, it is doubtful whether it will relapse or not. Undoubtedly, in adult tuberculosis, relapse does frequently occur. I also wish to emphasize the point that treatment of monarticular tuberculosis in children and that of monarticular tuberculosis in adults should be looked at from different points of view. In adults, operative methods should be employed; in children, conservative treatment.

Dr. Edward A. Rich, Tacoma, Wash.: We cannot look on the treatment of all tuberculous joints in any general way, saying that all these diseased joints everywhere in the body should be treated either conservatively or surgically any more than we could advise the treatment of all pulmonary diseases or of the exanthemas by hard and fast rules. It is true that there is a vast difference between the course and outcome of tuberculous arthritis in the child and in the adult. Also, it appears that the various joints in the same human body demand different courses of treatment to attain the best results in each one of them. Surgery seems to be most urgent in the region of the ankle. It is often our choice in the knee, while in the hip and spine the tuberculous process gives better results if treated conservatively. In taking up the treatment of joint tuberculosis, I think that it would be better to consider the joints individually rather than collectively, so great is the variance in the mode of treatment of the respective joints.

Dr. Willis C. Campbell, Memphis, Tenn.: The question of operation, it seems to me, depends a great deal on what you do and on the time when the operation is done. I do not believe that in late cases, after there is a considerable destruction of the bone about the joint, operation is of much value in accomplishing ankylosis. Early in the disease, in adult cases, if a small area of bone is removed (just enough to produce ankylosis), I think that good results can be accomplished. I have done several operations of this kind, but it is too early yet to say what the end-result will be. My service in the charity department is largely among negroes, and I find that, if something is not done for them early, no result is ever accomplished and amputation is inevitable. I think, therefore, that something should be done in order to see what can be accomplished by an operation—not for the removal of the disease, but for the purpose of producing ankylosis. In discussing operative and nonoperative treatment, most of us have the idea of the old type of operation—excision at the knee. We never do that. I do the Albee operation on the hip, removing a small area from the superior surface of the head of the bone and the corresponding area in the acetabulum. At the knee, I remove as small an amount of bone as possible, so that no deformity is produced by a lack of bone.

Dr. Henry Ling Taylor, New York: It seems to me that we should emphasize a few points more than they have been emphasized. In the first place, is there anyone in the United States who is doing major operations freely in the early stages of joint tuberculosis in children? If so, I should like to know of it, and say that I think it is unjustifiable. In adults, the problem is different. The matter of major operations for joint tuberculosis in children has been tried out extensively and dropped. Dr. Sayre tried it and abandoned it. It has been carried out in England by Wright, of Manchester, and abandoned; also in Germany. It has been abandoned everywhere that it has been tried. The results of the conservative treatment of these cases are so favorable in children that there is no reason for trying a radical operation. In adults, we have different pathologic conditions, different economic conditions, and, perhaps, different conditions of prognosis. The necessity in them for a radical operation in cases of tuberculosis is in proportion to the nearness of the disease to the end of the extremity, at least in the leg. When the lesion is in the spine, we cannot do a radical operation. I have seen spinal tuberculosis in adults entirely cured by conservative treatment, however; and I think that that is the only management open to us in these cases, except the Albee operation and the other methods of ankylosing the spine. The extirpation of the focus in children has been tried in the hip extensively by Tunstall Taylor, and abandoned; but we have good opportunities to try it in the knee and the ankle. These operations are sometimes advisable. Every once in a while, there is a case with a distinct focus that you can get at before the joint is involved, as proved by the pathologic findings after the operation. I look for these cases; and when I find them, I operate, and obtain good results. Another reason for operating in children is to save their lives. Sometimes the cases are so bad that you have to do something. Then you operate and extirpate the disease, either with an amputation or, if possible, a resection. Recently an English surgeon, Mr. Bennett, of Birmingham, told me that he has gone back to a modified excision of the knee in children, and thinks highly of it. He does an arthrodesis of the knee, shaving off the cartilage and a thin layer of bone, and he says that he does not get the bad results that we used to get in excisions in children. In adults, we can operate freely. If we have to sacrifice most of the joint, we do not have to sacrifice anything that has not already been sacrificed. Even if motion is present, it will not be when the case is finished; or be anything but a detriment, if it is present. The object then is to ankylose the joint.

Dr. Reginald H. Sayre, New York: I should like to put myself on record as practically agreeing with everything that Dr. Taylor has said, except that he seems to be under an erroneous impression in regard to my father's stand in operating on early tuberculosis. When he first excised hips, he was not allowed to operate on any but persons who were almost dying, or who were full of sinuses and certain to die, if left alone, in a few weeks. The general consensus of opinion at that time was much opposed to it. In his writings, my father said: "When this operation is regarded as justifiable by the medical profession, they will have progressed far enough in the ability to make accurate diagnoses that the operation will cease to be of use; for the cases will not be allowed to go on until they require resection of the joint."

Dr. Newton M. Shaffer, New York: I have listened with a great deal of interest to this discussion, because it brought back to my mind my old experience with Dr. Taylor and Dr. Sayre, and my own experience in the Orthopedic Hospital and the Children's Hospital. I agree with what seems to be the consensus of opinion; and that is, that conservative treatment should be applied in almost every instance of tuberculous disease of the joints of the lower extremity. I have amputated in only one case; and I think that that was a mistake. Of course, we all know that excision of the joint is inadvisable; and I wish to repeat what I said at the first meeting of the American Orthopedic Association, that excision of the hip-joint is impossible. That is, we can decapitate the femur; but the acetabular wall is so thin that excision of the hip should really be called decapitation of the femur. I did one or two of these operations in St. Luke's Hospital. Dr. Sabine and I selected some incipient cases and excised them, only to set up an irritation. I have a rule that I regard as invariable for the treatment of cases in the knees of adolescents and adults. I am simply repeating what others have said, but I wish to confirm their opinions. In an adolescent shop-girl or a boy going to school, I would advise against spending the long period of time required to secure the result by conservative measures. Therefore, I almost uniformly recommend an excision in these cases. When it comes to the spine, Dr. Griffith's statement that he makes his diagnosis in such cases after the result is obtained, classifying them as nontuberculous or tuberculous according to what is found, is interesting. We all know that spinal disease often does cure itself. I have seen a good many cases of cure with practically no treatment. It was, I believe, the original idea that first suggested the use of spinal support that as soon as the ribs in Pott's disease reached the pelvis, the disease began to cure itself, owing to the support obtained from the ribs resting on the pelvis. I have seen cases of cured Pott's disease of tuberculous origin. I know that the patients were cured, because they remained well for years. The liability of relapse in the knee or hip of the adolescent is great. Only a year ago, I saw a patient that I had treated fifteen years ago, at the Orthopedic Dispensary. She left the dispensary with a fairly flexible knee, but she now has a worse case than she had when I first saw her. She will not submit to excision, but I quite agree with the others who have spoken that this would be the best treatment for the case. As some of you know, I was once abused for not advising operative interference for cold abscess, but conservative measures. That has now become the accepted form of treatment.

Dr. H. Winnett Orr, Lincoln, Neb.: I have deliberately taken the attitude on this question of arguing against the double standard of treatment for adults and children with joint tuberculosis. The differences in pathology between this condition in children and in adults are, I think, not so great as has been suggested. So far as my own series of cases is concerned, five of these were in adults, three of whom have remained well for a year or more, without operation. One of these patients, with a tuberculous knee, was 26 years of age; one, with tuberculosis in the spine, 32; and the third, with tuberculosis of the wrist, 48. How long they will remain well, I cannot say. With due apologies to Dr. Porter, I would say that while they may not be tuberculous, they have every indication of being so. I regard a good result in these cases as being not necessarily the restoration to function of the involved joint, but a return to function of the individual, which I consider to be much more important. No one maintains that in any considerable number of the cases, with or without operation, there will be a return of the joint to the normal; but in these cases that I have studied, the patients were much worse off after operation than patients of the same class without operation.

Another thing that I wish to say is, that the fact that many of these patients, adults who have been treated conservatively, do not do so well as children is partly because they are usually not well controlled. This is mostly, of course, the fault of the patients; but if the adults were as well controlled mechanically as children practically always are, they would do better, and perhaps more frequently recover than they now do.

With regard to methods of treatment, I would not care to say much, except that I have paid more attention to fixation than to any other element in the treatment, especially with adults whom you cannot keep in bed and to whom we cannot apply the methods that are used so extensively in the cases of children.

THE WHITMAN OPERATION FOR TALIPES CALCANEUS PARALYTICUS *

JOHN PRENTISS LORD, M.D.
OMAHA

During the last year I have done the Whitman operation twenty times on eighteen patients, and the immediate results have been so gratifying that I am most enthusiastic in indorsement of the operation. At a clinic given before the American Orthopedic Association in New York, May, 1912, I was privileged to witness the performance of the operation by its author. Prior to this time its full technic had not been sufficiently comprehended to justify its adoption. But my indifferent results had stimulated my special interest. The results in very numerous cases there exhibited were convincing. A personal communication from Professor Whitman states that few, besides himself, do the operation in New York. It is my observation that too few surgeons employ this method of radical relief, and I, therefore, desire to aid the cause of its popularization through the report of the results of my experience.

The operation has a wider range of application than for calcaneus alone and may be modified by various tendon transferences to meet special indications.

The primary indication in extreme cases of paralytic deformity is the establishment of stability. The secondary indication is the utilization of available muscle power for a balanced action and maximum of function; these attained, there is little or no tendency to a relapse of the deformity.

The fault of the operations which deal with muscles and ligaments only, in cases inherently weak because of extensive muscular deficiency from paralysis, is that the soft parts yield to the subsequent strain put on them and relapse in greater or less degree, unless, perchance, a careful after-supervision and the use of artificial supports is continued indefinitely. But recurrence is inevitable in many, unless a more distinctly radical operation is done. This is afforded in the Whitman procedure, which was primarily devised by him for extreme calcaneus paralyticus. It is now demonstrated to be useful in other varieties of talipes characterized by great instability. It should also be used in patients destined to develop the deformities for which it is indicated. This is pursuant to a distinct tendency now existent to do definite things for the crippled and deformed, instead of palliating or temporizing for months or years, conditions which should, if possible, be permanently corrected at the outset.

The Jones operation for talipes calcaneus has a more distinct indication in the fully developed calcaneus deformity in the adult foot. It is a two-stage procedure and has been little used in this country.

DESCRIPTION OF OPERATION

The Whitman operation as described by its author is in abstract: "astragalectomy, arthrodesis, tendon transplantation and backward displacement of the foot." The following is the description in detail:

A long, curved, external incision is made passing from a point behind and above the external malleolus below its extremity and terminating at the outer aspect of the head of the astragalus. The peronei tendons are then divided just in front of the malleolus, completely separated from their sheaths and drawn backward. The lateral ligaments are next divided and the joint is opened. The interosseous ligament is cut through and the foot is twisted inward. When the attachments to the navicular have been freed the astragalus may be removed. A thin section of bone is then cut from the outer surface of the adjoining os calcis and cuboid, and on the inner side the calcaneonavicular ligament is partially separated from its navicular attachment. The lateral ligaments are freed from the two malleoli and the cartilage is removed from their inner surfaces. The foot is then displaced backward as far as possible so that the external malleolus may cover the calcaneocuboid junction, while the inner is forced into the depression behind the navicular, the malleolus being changed in shape if necessary to assure accurate adjustment. Finally, the peronei tendons are drawn through an opening in the tendon Achilles, or they are sewed to it and then reunited to their respective tendons with strong silk sutures. The wound is closed without drainage, and the foot is then held in an attitude of equinovalgus by a plaster bandage fixing the leg at a right angle to the thigh. The object of the removal of the astragalus is to assure stability and to prevent lateral deformity by placing the leg bones directly on the foot. Incidentally it restores the symmetry of the foot. The object of the backward displacement of the foot is to direct the weight on its center and thus to remove the adverse leverage and to prevent dorsal flexion by direct contact of the tarsal bones with the anterior margin of the tibia. The tendon transplantation is an additional safeguard against deformity and of service in restoring function. In about three weeks the long plaster is removed and a short one is substituted, the foot being fixed in moderate equinus by a cork wedge beneath the heel. On this the patient is encouraged to walk. The plaster support may be used with advantage for six months or a light brace may be substituted for it. Eventually the brace is discarded and a shoe with a cork inner sole adjusted to the attitude of plantar flexion is substituted.

Whitman says that he "usually thickens the sole one-fourth inch on the outer border to guard against the inclination toward varus. If all the details are properly carried out, particularly the backward displacement and adjustment of the malleoli, the result is a symmetrical foot, a movable ankle-joint, and yet a secure support that eventually enables the patient to dispense with the braces."

SUMMARY OF OPERATION

In brief, the Whitman operation for talipes calcaneus consists of:

1. The removal of the astragalus.
2. The freeing of the malleoli and the preparation of a new articulation.
3. The transplantation or resuture of the peronei tendons.
4. The backward displacement of the foot.
5. The fixation of the foot in equinus.

After-Treatment.—A fixation plaster is kept in position for about four weeks, then an ambulatory plaster is used for about five months.

Results.—Cavus and lateral instability are corrected, the backward displacement checks dorsal flexion by direct contact and by change in leverage, and the power of the transplanted muscles is made more effective.

OBSERVATIONS

This operation is called radical because it restores symmetry and assures stability. It is the only effective procedure for an advanced deformity and it is also indicated in early cases as a preventive of progressive deformity.

---

* Read in the Section on Orthopedic Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

I have done many astragalectomies, arthrodeses, tendon transferences and silk implantations for these various paralyses of the feet during several years, but not until I had seen actual results from the Whitman procedure was I willing to adopt it.

The failure of many tendon transferences and silk implants is due to too much dependence being placed on weakened and easily over-stretched muscles and insecure silk attachment, whereas, if the midtarsal joints are ankylosed by arthrodesis the transferred muscles will not yield to overstrain and will serve a beneficial purpose. In the extreme cases the Whitman operation will be found to give greater stability because one articulation, the tibio-astragaloid, is eliminated, hence mobility is lessened. Feet which have had the Whitman operation performed on them do not wobble or roll over, nor do they show a tendency thereto.

Many of the relapsing cases of paralytic talipes equinovarus have by previous forced corrections had the external malleolus forced backward until the fibula is almost beside the Achilles tendon. The tibio-astragaloid joint is much too far backward to allow of a sufficient degree of stability to the foot. The few remaining extensors are under too great a handicap to control such a foot. Tendon transferences alone under such circumstances are failures, or, at least, disappointing. Supplemented by arthrodesis the results are better, but, done early, arthrodesis is not of lasting benfit because too free motion is in time established. It is my opinion that the indications are not so well met by any of these procedures as by the Whitman operation, modified as necessary by tendon transference and silk implantation. In the Whitman operation weight-bearing is farther forward and lateral motion is eliminated. The motion is adequate and the foot is stable. Without the overload otherwise existing, the well utilized transferred muscle power may be adequate to give a fair degree of extension for the toes.

The overstrong calf muscles may be so divided and transferred as to control the inherent tendency to deformity. Thus for many weak, deformed and unstable feet the modified Whitman operation would also seem to afford the maximum operative relief.

Cases of extreme paralysis with a potential deformity, are suitable for this treatment. The feet destined to develop the various forms of talipes for which this procedure is subsequently indicated may be operated on before the exaggerated conditions are developed, and thus prevent their development. By these means, therefore, the long discouraging course of less radical procedures and the attendant anxiety of the parents and surgeons may be avoided, in my opinion, as is also claimed by Whitman, whose efforts to popularize his operations have not been so successful as their merits warrant. The restoration of contour, the fixation and the early restored function are all in its favor. Most of these patients resumed the use of their feet within three or four months and their ultimate permanent improvement is quite fully assured. The time is still too short in the later cases, however, for final conclusions.

On further study of the cases I am free to admit that in some of the earlier ones improvement could have been made if later and more mature experience had been available. The typical or stereotyped operation is not to be adhered to, because indications vary, especially when the operation is performed to ameliorate conditions other than the one for which the operation was originally devised.

501 Paxton Building.

ABSTRACT OF DISCUSSION

DR. CHARLES A. REED, Minneapolis: I had the pleasure of assisting Dr. Whitman in doing this operation fifteen or twenty times and have watched the results in the patients as they returned to the dispensary of the Hospital for Ruptured and Crippled. The results are as satisfactory as are obtained in the treatment of any other form of deformity with which I have had to do. I have used it in my practice a number of times since. I should like to mention one feature, and that is that the displacement of the leg forward on the foot may look as though it were complete at the time of operation, and then as it heals it often seems to slip back. The cases in which the operation was not fully successful were those in which the forward displacement of the tibia was not complete. All the cases in which I have done this operation have been cases of talipes valgus rather than varus. I have never realized that it was indicated for varus deformity; but it certainly is satisfactory in valgus, which is a more difficult deformity with which to contend.

By shortening the tendons it is often possible to obtain good functional results even in those cases in which the muscles are practically all paralyzed because the result is a firm fibrous union.

DR. WILLIS C. CAMPBELL, Memphis, Tenn.: I have seen a great deal of the work of Dr. Whitman and of his results. His results seem to be exactly as Dr. Lord has told us. I have done the operation five or six times, and, in every instance, with great success. I feel that the operation has a wider range of usefulness than is generally considered.

All my cases have been valgus cases, with the exception of one, which was a varus case. There are some points in doing the operation that are important and interesting. Dr. Lord did not go into the details. One of these is holding the foot in exactly the proper position, displacing the tibia backward between the malleoli, and at the same time holding the foot in a moderate equinus position. Many of the failures in the operation are, I think, due to the fact that the foot is not held in the proper position at the time of operation; the actual slipping probably occurs then, and not later. I have had absolutely no trouble in my few cases. The parts were all in good relation when the cast was removed and have remained so. The oldest operation has been done just two years at the present time, and the result is just as good now as it was at first. The special indication for the operation is when there is only paralysis of the leg below the knee. In these cases, it gives a good, stable foot, and one that is elastic. It has the advantage over arthrodesis in that the patient has elasticity and has not the discomfort in walking on uneven ground that is experienced by those on whom arthrodesis has been performed.

DR. JOHN PRENTISS LORD, Omaha: I am glad that Dr. Campbell brought out the importance of the equinus position in doing this operation. We have been particular about this, and the equinus position has been greatly exaggerated. It is important, however, to bear in mind that it is an abnormal position, one that you would not care to have permanent; and to be especially careful to modify the position to the final degree desired, at the three-week's period, when the initial cast is removed. It is to be borne in mind that this is highly essential; because one of the chief features of the operation is the securing of an anterior position to the joint. I think that one reason for the failure of other operations of all kinds is the fact that the foot has been so unstable that the enfeebled muscular power and laxity of the ligaments could not be expected to give a firm foot. The importance of stability is a great factor, and I think that this is the secret of the indication for the operation. We have heard a great deal about the unsatisfactoriness of muscle transference, silk implantation and all that sort of thing. It is because too much is expected from that kind of support. If you once render the foot stable and put the bony framework into position to do its part with the least amount of strain on the inherently inadequate soft parts, you will then comprehend the real advantage of the Whitman operation; because it does give stability, it puts the muscular leverage to the greatest advantage. While speaking of this, I wish to mention the great necessity for giving particular attention to this when you depart from the original indication for the Whitman operation and do that operation for conditions in which the muscles in the posterior part of the leg are overacting. If my work is to be criticised, I would say that I have subjected it to the criticism that I had *not given sufficient* consideration to the fact of muscle power in the calf muscles, particularly when an overadvantage is given them by dislocation of the foot backward. We should therefore redistribute the pull on such feet.

I did not mention, in considering the after-care, that these patients always have short legs, and that you have still further shortened the foot and leg by the elimination of the astragalus. It is highly essential, therefore, that one shoe should be slightly raised. The size of the foot is reduced, so that it can be placed in a large shoe with practically all of this extension let into the inside; so that the deformity is not conspicuous. These patients, however, should not be expected to have their feet firm at a right angle. They should be made to maintain a slight equinus position.

THE RELATIVE VALUES OF THE ROENTGEN RAY AND THE CYSTOSCOPE, IN THE DIAGNOSIS OF VESICAL CALCULI *

Edwin Beer, M.D., New York

The surgeon who sees a great deal of bladder material is well aware of the fact that roentgenoscopy does not regularly demonstrate vesical calculi. During the past two years I have had this experience so frequently that I have deemed it my duty to review all the cases of bladder stones in which I have had a roentgenogram taken and to place them in a brief paper before the medical public. I have considered this advisable, as the average internist is very liable to be satisfied with a negative roentgenogram in excluding the presence of a calculus in the urinary bladder.

The Roentgen-ray work done on these cases (by Dr. Jaches) has been of the highest quality; therefore the fact that so many of the cases showed no stones can in no wise be attributed to the radiographic work. It is only fair to state that the Roentgen-ray work was of the routine type, one plate for the kidneys and one for the pelvic portion of the urinary tract. I believe that the following array of cases will show rather conclusively that even plates so carefully made will miss stones in the bladder with considerable frequency.

During this period I have had twenty-two cases of vesical calculi radiographed. In only six cases did the calculi show in the roentgenogram. On the other hand, in every case the diagnosis was made with the cystoscope. Of the sixteen negative cases, the calculi were examined chemically in nine cases by Dr. S. Bookman. These nine cases showed the following chemical composition:

Case 1: Ammonium urate with small amounts of calcium carbonate and ammonio-magnesium phosphate.

Case 2: Uric acid and traces of calcium and magnesium phosphate.

Case 3: Ammonium urate.

Case 4: Uric acid and traces of calcium and magnesium phosphate. (This was a renal calculus that had wandered into the bladder.)

Case 5: Sodium and potassium urate and uric acid.

Case 6: Uric acid and ammonium and sodium urate.

Case 7: Ammonium urate.

Case 8: Ammonium urate.

Case 9: Uric acid and traces of calcium oxalate.

In these sixteen negative cases, nine patients had prostatic adenoma as well.

From these data it is evident that the cystoscopy is a much more reliable diagnostic aid in vesical calculi than roentgenoscopy. How frequently similar stones escape the radiographic examination in the upper urinary tract, I would not venture to say, though such cases as No. 4 are probably not so rare as most surgeons at the present day believe. Perhaps with improvement in technic and newer methods, which will coat the calculi with a layer of salts that does not allow the rays to traverse the modified calculus with equal ease, it may become possible to demonstrate all of these uric acid and uratic calculi both in the upper and in the lower urinary tracts.

48 West Seventy-Fourth Street.

A STREPTOCOCCUS PRODUCING SYMPTOMS OF CHOREA IN A DOG *

George F. Dick, M.D., and T. Rothstein, M.D., Chicago

The streptococcus spoken of in this report was isolated from the throat of a patient with a case of chorea of five years' duration. Similar organisms have been isolated from a number of cases of more acute chorea. A detailed report will be published in the *Journal of Infectious Diseases.*

The streptococcus as grown on blood-agar forms a heavy, dirty-white growth with a border well raised above the medium and a wide zone of hemolysis. It grows aerobically and anaerobically equally well and grows on all ordinary media. It ferments milk with slight acid production but no coagulation. It does not ferment dextrose, lactose, mannite, inulin or saccharose. As grown on the surface of agar-slants, the streptococcus is a Gram-positive organism occurring in irregular groups and short chains with such an abundance of smaller Gram-negative forms as to give the impression of a mixed culture. In milk it grows in extremely long chains, and staining fails to show a capsule.

A dog which was injected intravenously with the growth from four agar-slants developed choreic movements within twelve hours.

122 South Michigan Avenue.

A SCARLATINIFORM RASH FROM ATOPHAN †

W. W. Herrick, M.D., New York

Assistant Physician, Roosevelt Hospital

The patient, a woman aged 38, was admitted to the Medical Service of Roosevelt Hospital May 30, 1913, suffering from an acute polyarthritis involving knees, ankles, wrists, cervical spine, the temporomaxillary and many interphalangeal joints. The maximum temperature was 103. There was no history of previous attacks nor was there any cardiac involvement.

Drug treatment was begun with large doses of sodium salicylate, 240 grains being given each twenty-four hours, from May 30 to June 4. The temperature fell to 101, but pain was not relieved. June 4 the sodium salicylate was discontinued and atophan 15 grains given three times a day to June 7, when the same dose was given every four hours. This was continued until June 11, when the dose was made 7½ grains every four hours. Pain was relieved and the temperature fell to 99.

June 13 there was a sudden rise of temperature to 103 with headache, vomiting and prostration, all without return of joint symptoms. Within three hours a rash appeared on the chest and neck, spreading thence to the remainder of the trunk and the extremities, but not to the face or scalp, which remained free from the exanthem. This rash was at first a punctate erythema which later by coalescence of the thickly placed spots became diffuse on the chest, while preserving a more macular character on the abdomen and extremities. The mucous membranes were not involved. Atophan was immediately discontinued and within forty-eight hours the eruption faded, disappearing after three days. This rash was strikingly like that of scarlatina both in appearance and distribution. There were, however, no throat or other symptoms to suggest this disease.

---

* From the Genito-Urinary Surgical Service of the Mount Sinai Hospital

* From the Memorial Institute for Infectious Diseases, Chicago.

† From the Medical Service of the Roosevelt Hospital.

As a matter of experiment, on June 16, atophan 45 grains was given within twenty-four hours and was followed by a chill and a sudden rise of temperature to 103, these symptoms subsiding on again discontinuing the drug. There was no skin rash at this time.

So far as I can discover no instance of skin eruption from atophan has been reported. Such effect is doubtless due to the quinolin nucleus of the 2-phenylchinolin-4-carbonic acid and is therefore analogous to the rashes observed in certain individuals after the administration of quinin. Consequently one may well expect to meet with occasional erythemas and urticarias from the use of this drug. Our own patient was given quinin at a later time and showed no evidence of idiosyncrasy.

49 East Fifty-Third Street.

A Simple Method for the Relief of Ordinary Fainting.—While attending St. Peter's Hospital in London in 1899 I was impressed with a simple procedure in daily use for the relief of this condition. It was the custom of the surgeons at that time, Mr. Reginal Harrison, Mr. E. Hurry Fenwick, Mr. P. J. Freyer and Mr. F. Swinton Edwards, to pass bougies and sounds with the patient standing. The many patients would form themselves in a long line and occasionally one of them would become faint, sometimes even before the instrument was passed. It was the custom to have a vacant chair beside the surgeon who, when he noticed the condition of the patient, would have him seated in the chair, and the surgeon or his assistant would press the patient's head down between his (the patient's) knees, thereby lowering the head below the trunk, and by forcibly flexing the head on the chest retard the return circulation and thus relieve the anemia of the brain. Holding down the head for a minute is sufficient. I have seen this done many times and since then I have done the same and have thereby saved myself much annoyance. If at the minute the patient shows the first sign of becoming faint the head is pressed well down between the knees, it will be unnecessary to use the horizontal decubitus. This method works beautifully in a crowded room or car.—John A. Hawkins, M.D., Genito-Urinary Surgeon to South Side Hospital, Pittsburgh, Pa.

New and Nonofficial Remedies

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

NINHYDRIN.—Triketohydrindenhydrate.—Ninhydrin is phenyl-1,2-triketo-cyclopropane hydrate  $C_6H_4\left<\begin{matrix}CO\\CO\end{matrix}\right>C(OH)_2$, a derivative of inden (phenyl-1,2-cyclopropene)  $C_6H_4\left<\begin{matrix}CH\\CH_2\end{matrix}\right>CH$

Ninhydrin occurs in the form of colorless crystals readily soluble in water. When heated it becomes red at 125 C., swells at 139 and melts at 239-240 C. The aqueous solution colors the skin violet and reduces Fehling's solution. When heated to the boiling point in aqueous solution it gives a blue color in the presence of protein bodies or amino acids derived from them which have the amino group in the alpha position in relation to the carboxyl. It gives this reaction with compounds that no longer respond to the biuret reaction.

Actions, Uses and Dosage.—Ninhydrin is not employed therapeutically. It is used as a reagent for determining the presence of albumin, peptone, polypeptids, and amino acids. This test is especially applied to demonstrate the presence in blood serum of specific proteolytic ferments, especially in the diagnosis of pregnancy, according to the method of Abderhalden.

10 c.c. of the material to be tested is mixed with 0.2 c.c. of a 1 per cent. aqueous solution of ninhydrin, the mixture heated to the boiling point and kept boiling exactly one minute. The presence of amino acids or their protein compounds is indicated by a distinct blue color of the liquid.

The biologic test for pregnancy according to Abderhalden is carried out as follows:

About 1 gm. of coagulated placental tissue is boiled with ten times its volume of water, and the water poured off and this treatment repeated until the liquid contains nothing which will give a reaction with ninhydrin. When it no longer responds to the ninhydrin test it is placed in a diffusion cell with 0.65 c.c. of blood serum free from hemoglobin, and the mixture is allowed to diffuse into 20 c.c. of distilled water. Both the dialysate and the liquid in the cell are covered with a layer of toluene. The dialysis is continued for from twelve to sixteen hours in the incubator at a temperature of 37 C.

To 10 c.c. of the dialysate 0.2 c.c. of a 1 per cent. aqueous ninhydrin solution are added, and the test performed as described above. If a blue color results the serum has been derived from a case of pregnancy.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a.M., Germany (Farbwerke-Hoechst Co., New York). No U. S. patent or trademark.

PLACENTAPEPTON.—Placentapepton is a preparation of peptone derived from the placenta and employed for the purpose of the optical test for pregnancy according to Abderhalden.

Placentapepton is a yellowish powder, soluble in water and having the properties of peptone.

Actions, Uses and Dosage.—One c.c. of the serum to be examined, which must be absolutely free from hemoglobin, is mixed with 1 c.c. of a 5 per cent. solution of placentapepton in 0.9 per cent. solution of sodium chlorid. This mixture is placed in an Abderhalden polarization tube of 2 c.c. capacity surrounded with a water jacket. The rotation is immediately determined. The polarization tube is then placed in the incubator and examined at intervals of two hours at first and later at longer intervals for the amount of rotation. This test of rotation should be continued not longer than forty-eight hours. Only variations of 0.05 degree are to be regarded as essential changes in the rotatory power. Placentapepton cannot be employed in the diffusion test for pregnancy.

Manufactured by Farbwerke, vorm. Meister, Lucius & Bruening, Hoechst a.M., Germany (Farwerke-Hoechst Co., New York). No U. S. patent or trademark.

ANTIRABIC VACCINE.—Lederle Antitoxin Laboratories, New York City. (Schieffelin & Co., New York.)

Rabies Vaccine.—Rabies vaccine is prepared according to the method of Pasteur and is a complete treatment, consisting of 25 doses, to be administered during 21 days. Each day's injection is shipped in a vacuum bottle. Complete description and directions accompany each outfit.

NON-PROPRIETARY BRANDS OF ACCEPTED ARTICLES.—Having been found to comply with the standards adopted, the Council voted that the following brand of an accepted article be listed:

Copper Citrate, Merck.—Manufactured by Merck & Co., New York.

Transfer of Agency.—The biologic products formerly manufactured by the Sophian-Hall-Alexander Laboratories, Kansas City, Mo., (described in The Journal, A. M. A., April 5, 1913, p. 1074, and April 19, 1913, p. 1227, Sept. 6, 1913, p. 771) are now manufactured and sold by E. R. Squibb & Sons, New York.

THE RELATION OF NUTRITION TO TRANSMISSIBLE TUMORS

If one may judge by the direction which experimental work in relation to the cancer problem has taken in recent years, the greatest promise of any considerable degree of success in unraveling the secrets of these neoplasms lies in the study of the transmissible tumors of animals. The considerable experience now available in many laboratories in diverse parts of the world shows that conditions are attainable in which these tumors can be brought to quite a constant degree of virulence as measured both by the percentage of positive inoculations and by the rate of growth on a given lot of animals. But when the same growth is tried on different strains of test animals in remote places the apparent virulence of the tumors shows variations which have hitherto largely baffled all attempts at a rational explanation. We are told with respect to the so-called spontaneous tumors of mice that a breeder may find a large number of tumors among his animals, but that they can rarely be transplanted successfully. A large number of the subcutaneous adenocarcinomas are not transmissible even to mice of the same strain.

Such facts raise the question as to the underlying reason for the variations in susceptibility or immunity of the host. The incidence of sex, age and heredity has been taken into account by different investigators. By some it has been believed that when a nutritive tax is put on the organism, as happens during pregnancy or when a person is ill or undernourished, conditions might be found relatively unfavorable for growth in general, the neoplasm included. Against this may be arraigned the view that precisely under conditions of poor nutrition is immunity at a lower ebb. In so far as pregnancy is concerned, we are reminded that the conditions then obtaining may be expected to stimulate rather than retard growth.[1] The situation with respect to the possible bearing of age and heredity is no less confused.

The foregoing considerations involve in essence what may be termed the internal conditions modifying growth, in contrast with the external factors, such as light, climate and diet, which are independent of the individual involved. Most of the work on the influence of diet has, until quite recently, been of a desultory character. An unfavorable influence of poor nutrition brought about by intercurrent disease has, it is true, been reported; although instances of actual partial starvation have not yielded the same outcome.

Sweet, Corson-White and Saxon[2] have followed a somewhat new path in the study of the relation of nutrition to transmissible tumors. Their plan was based on the feeding experiments of Osborne and Mendel.[3] The latter investigators have shown that it is possible to maintain rats for considerable periods of time on diets composed of isolated foodstuffs, including fats, carbohydrates, inorganic salts and a single protein. The possibility of growth in contrast with the mere maintenance of animals on such dietaries is dependent on the nature of the protein fed. Thus they were able by special selection of the ingredients of the diet to maintain young (ungrown) animals in health for long periods without any evidence of increase in size. In other words, their animals were not starved in any sense except a very specific one—certain substances essential for satisfactory growth were lacking. Sweet and his colleagues at the laboratory of the American Oncologic Hospital in Philadelphia have applied this newer knowledge of the unlike conditions governing nutrition in growth and maintenance, respectively, to the behavior of transplanted tumors. They asked themselves: Regardless of whatever may be the ultimate cause of cancer, can a cancer grow in a body rendered incapable of normal cell growth?

Inoculated rats and mice still capable of growth were placed on the Mendel-Osborne stunting diet, and others on the customary mixed food. The results are of surprising interest. The number of successful transplantations was remarkably reduced by a diet which prevents normal body growth. The rate of growth of the tumors which do "take" is much slower on the stunting diets than on the control food, and the number of retrogressions is high on such a diet. The effect is not only exerted on the reciprocity of the host, but retrogressions also occurred on the Mendel-Osborne diet, though not among the control animals.

The clear-cut demonstration of the possibility of influencing the growth of transplantable tumors by proper diets opens up new avenues of research and encourages a continuance of the studies begun in this direction.

THE OPEN-AIR TREATMENT

It sometimes happens that when the current explanation of a phenomenon is disproved the impression is produced in some minds that the occurrence of the phenomenon itself is denied. Something of this sort has taken place with reference to the recent work on the physiologic factors involved in room ventilation and the open-air treatment. There is reason to believe that the general public is still in some confusion on this point. It was for a long time supposed that the bad effects of close and crowded rooms were due to chemical impurities in the air, to excess of carbon dioxid or to organic poison, or else to oxygen impoverishment. No one of these explanations is tenable in the light of recent experiment. On the contrary, all the ill effects observable in crowded rooms seem to depend on the stagnation, high temperature and moisture-content of the air; in a word, to those factors that produce a disturbance of the normal heat regulation of the body. If the temperature and moisture are kept low, human exhalations may be allowed to accumulate without noticeable effect to a point far above that ordinarily observed in the most "badly ventilated" room. On the other hand, if the experimenter breathes "pure" outdoor air through a tube but allows his body to be confined in a small chamber where temperature and moisture are at a high point, he will soon have all the symptoms commonly attributed to "breathing foul air."

[2] Sweet, J. E.; Corson-White, Ellen P., and Saxon, G. P.: The Relation of Diets and of Castration to the Transmissible Tumors of Rats and Mice, Jour. Biol. Chem., 1913, xv, 181.

[3] Osborne, T. B., and Mendel, L. B.: Beobachtungen über Wachstum bei Fütterungsversuchen mit isolierten Nahrungssubstanzen, Ztschr. f. physiol. Chem., 1912, lxxx, 307.

To substitute this explanation, which is wholly in accord with recent experimentation, for the once-current theory that expired air has a toxic property is not to question the value of fresh air or to decry the open-air treatment for tuberculosis. On the contrary, we are in a much better position to understand in what way cool air and especially moving air produces marked invigoration and improvement of the general health. When the body loses heat at a suitable rate, heat production must also proceed at a certain rate in order to compensate for the loss, and metabolism is increased at equal pace. Increased metabolism means improved quantitative and qualitative assimilation of food; and, as Hill has pointed out, a larger consumption of food means a wider choice of "building-stones." The action of cool, moving air on the skin and cutaneous nerves is probably in itself beneficial. Moreover, it impels to exercise, and an increased activity on the part of the body increases metabolism.

On the other hand, exposure to the stagnant atmosphere of confined places allows the skin to become surrounded with an envelope of warm air which prevents the body from losing heat at a proper rate. The nerve-endings of the skin are not stimulated. The circulation is depressed. Reluctance to exercise and to any bodily exertion becomes marked. Expansion of the lungs and oxygenation of the blood are less frequent and thorough. Metabolism is sluggish. Insufficient food is taken to supply the demands of the tissue for variety, and much of the food eaten may decompose in the intestine and produce toxic products.

Altogether there is still a sound physiologic foundation for the belief in the virtues of the outdoor life for the healthy as well as for the tuberculous person. In point of fact, nothing can discredit the rational open-air treatment, no matter what progress physiologists and hygienists may make in analyzing the mechanism on which this treatment rests.

THE BACILLUS OF CONTAGIOUS ABORTION IN COW'S MILK

A recently issued report from the Bureau of Animal Industry of the United States Department of Agriculture[1] calls attention anew to the infectious abortion of cattle, a disease which ranks second only to tuberculosis, and in certain sections of the country occasions even greater money losses. When we recall further that an infection of insidious character, in which there is practically no apparent change in the health of the mother prior to the abortion, can bring about the loss of the offspring, the loss occasioned by a reduction in the milk-supply, together with the failure to conceive for several months or at all after the abortion, the seriousness of the epizootic becomes apparent.

The causative agent in the infectious abortion of cattle has now been identified as the *Bacillus abortus.* The virus can be introduced into the body in various ways, such as the digestive tract, the vagina and perhaps the respiratory passages. No matter what the mode of natural infection may be, it is obvious that the bacillus of abortion shows a predilection for the mucous membranes of the uterus. The organism can be disseminated in a great variety of ways, for it has been found in the after-birth, the fetus and the vaginal discharges of the aborting animal, all of which serve as modes of spreading the infection. Milk has recently been added to the number of agencies by which the virus is eliminated from the body. Inasmuch as experimental animals, such as guinea-pigs, develop marked pathologic lesions in various organs and tissues when such naturally infected milk is injected into them, one is constrained to inquire into the possible pathogenicity of the *Bacillus abortus* for man. The government experts have appropriately pointed out that the common occurrence of a micro-organism, pathogenic for any species of animal, in an article of food as widely and as extensively used as milk, demands attention. This is the more true because premonitory symptoms of the disease are by no means always observed in the infected cattle, so that there is no occasion to expect any contamination of the milk from them. One is dealing with an organism that has the udders of apparently healthy cows as its normal habitat and which therefore cannot be certainly excluded from the milk no matter how much cleanliness and care are used in its production. The newest data show quite conclusively that the bacillus of contagious abortion of cattle—the organism producing tuberculosis-like lesions in guinea-pigs—may be eliminated continuously for years in the milk of infected cows that no longer abort. Although nothing is yet known about the possible effects of this infective agent on human beings, we can scarcely afford to assume that they are not affected by an organism which causes progressive lesions of a serious character in experimental animals. Chief Melvin points out that this bacillus may prove to be another source of danger in the use of raw milk as food and may furnish an additional reason for taking advantage of the safeguard afforded by the proper pasteurization of all milk before it is used as a food.

---

[1] Infectious Abortion of Cattle and the Occurrence of its Bacterium in Milk, Twenty-Eighth Ann. Rep. Bur. Animal Ind. for 1911, Washington, 1913, p. 137.

The animal diseases, such as the one here detailed, may concern the physician either directly as a possible source of human disorder, or indirectly in that they curtail the food-supply or the comfort and convenience of mankind. It is apparent, therefore, that we must be alive to every new finding in the field of veterinary pathology and the possibilities of its hygienic relations to mankind. Cow's milk has been assailed as the distributor of so many forms of human ills that one hesitates to entertain new charges against it until they are firmly substantiated. Nevertheless, sentiment must be overruled where hygiene reigns; and in the long run the frank recognition of hidden dangers or even harmful possibilities, such as those for which the bacillus of contagious abortion may become responsible, inevitably leads to preventive measures that are worth while from the point of view both of public health and of the economy of food production.

ALCOHOLIC FERMENTATION WITHOUT SUGARS

The production of ordinary alcohol, by the process of fermentation with yeast, out of substances other than sugars marks an event in science that deserves more than passing notice.[1] The subject of alcoholic fermentation has attracted the attention of chemists and biologists for generations. The outcome of the action of yeasts on sugar has long been expressed by an equation which indicates in chemical nomenclature: sugar = carbon dioxid + ethyl alcohol. As a matter of fact, neither of these end products of the reaction generated by yeast is present as preformed complexes in the sugar molecule. To any one with a chemical training it is apparent, therefore, that no simple disintegration of sugar by yeast will effect the familiar fermentation phenomena, including the rapid evolution of gaseous carbon dioxid. Indeed, the conviction has long gained ground among the initiated that instead of being eminently simple the fermentation processes are highly complex and that there must be one or more intermediary products in the transformation of sugar into the characteristic end-results of fermentation.

The epoch-making discovery of Buchner that alcoholic fermentation is quite as much an enzymatic process as the familiar transformations accomplished by the long-known digestive enzymes was significant. It showed that the reaction can, in a sense, be divorced from the actual life process of the yeast cell. The non-living, unorganized enzyme, zymase, can induce the typical gas production that had hitherto been inseparably associated with the continuance of organic existence in the yeast. Nevertheless this interesting fact has in no way served to solve the fundamental problem of fermentation, namely, the way in which its final products really are formed.

The researches of recent years have brought to light many new elucidating facts. It is not yet generally understood that prior to its fermentation sugar unites with phosphoric acid in fermentative mixtures; and in view of this important discovery of Iwanoff it is not sugar at all, but rather the phosphoric acid ester of sugar, that constitutes the primary object of attack by the yeast enzymes. A new importance is thus given to the compounds which accompany the pabulum of fermentation, and we begin to understand why the reaction has been so difficult to demonstrate when pure chemicals were used in place of the complex "mashes" of the industries.

There are various circumstances which point to the probability that sugar is first split into smaller molecules before it is subjected to the ultimate fermentative change itself; that is, the production of alcohol and carbon dioxid compounds with three carbon atoms, in place of the six of the fermentable sugars ($C_6H_{12}O_6$) have suggested themselves as the probable intermediate steps, for diverse chemical and biologic reasons. Lactic acid, $C_3H_6O_3$, and glycerol, $C_3H_8O_3$, are illustrations of such possibilities that have actual physiologic associations and are known to make their appearance under biologic conditions. Without detailed reference to others like glycerose, glycerol aldehyd, acetaldehyd, dioxyacetone, methylglyoxal, etc., all of which have been the subject of discussion, in this connection, we may direct attention to pyrotartaric acid, a compound which gives some promise of revolutionizing our current views of fermentation by yeast. It has been the merit of Neuberg and his co-workers in Berlin to demonstrate that this substance will give rise to carbon dioxid in typical fermentation fashion at once in the presence of yeast, as follows:

$$\underset{\text{Pyrotartaric acid}}{CH_3.CO.COOH} = \underset{\text{Carbon dioxid}}{CO_2} + \underset{\text{Acetaldehyd}}{CH_3.COH}$$

The significance of this reaction lies in the fact that it permits us to understand how an immediate production of gas may ensue from a substance like pyrotartaric acid which can be expected to be produced quite readily from sugar. Acetaldehyd, a product of the "sugar-free fermentation," is very closely related to ethyl alcohol. Neuberg has now actually succeeded by special devices in inducing a liberal formation of alcohol from pyrotartaric acid through the direct intermediation of yeast. Whether this takes place through the acetaldehyd stage or through some other more direct reaction is not yet ascertained.

---

[1] For details of this success see Neuberg, C., and Kerb, J.: Ueber die Vorgänge bei der Hefegährung, Berichte d. Deutsch. chem. Gesellsch., 1913, xlvi, 2225; Biochem. Ztschr., 1913, liii, 406.

It is enough to point out here that we are rapidly approaching a stage in the study of alcoholic fermentation in which each step can be understood and interpreted in terms of organic chemistry. The mystery of the yeast cell's behavior toward sugars is clearing up. Pyrotartaric acid looms up as something of biologic import. With the zymase of Buchner we may now align the new enzyme, carboxylase, of Neuberg. We begin to acquire light on how the six-carbon sugar chain may be torn apart into fragments of three, two and one carbon atoms. There are interesting prospects ahead, and they awaken the enthusiasm of students of medicine, because many of the life-phenomena of man have from time to time been interpreted by analogy with those of fermentation.

THE ENERGY TRANSFORMATIONS IN INDIVIDUAL ORGANS

Recent years have witnessed a greatly increased interest in what may be called the details of metabolism. Statements in regard to the energy changes of the body as a whole and the story of the gross nutritional needs of the organism have become familiar, if not commonplace. In a supplementary way attention is now becoming centered more and more in the chemical activities of localized parts of the body, and in the metabolic performances of organs and tissues; in the discovery of their specific peculiarities of function that may be quite as unique and distinguishing characteristics as are the recognized individualities of gross or minute structure. The progress which is bound to ensue from this newer point of view will serve to dispel much that has been vague in the domain of intermediary metabolism. We shall know more accurately and correctly what the special nutritive needs of organs like the liver, kidneys or brain are; to what extent their activities tax the energy capacities of the body which contains them, and precisely how their requirement for energy is to be satisfied in order to retain unimpaired physiologic efficiency. Furthermore, it is only a logical step to extend the inquiry and apply the methods of solution to the problems of pathologic function. It is time that some rational basis for the hitherto loosely employed statements about the "overworking" of one organ or another—the kidney, for example—be forthcoming.

In the beginnings which have been made in this new field of investigation various methods of research have contributed useful help. Organs of the higher animals and man are now successfully isolated from the body and "kept alive" by perfusion methods. The present generation of physicians can recall the older classic illustrations of such extracorporeal maintenance of function. The frog's heart and the muscle-nerve preparation from the leg no longer stand out as the conspicuous illustrations of isolated function. Almost every larger organ has been isolated and "perfused" with success. Again, the metabolism of the body as a whole can be studied before and after extirpation of the organ that is under investigation, and the differences thus brought out may be interpreted in relation to the part involved. The estimation of the differences in the quality of the blood before entering and after leaving an organ—a method especially developed in England—furnishes valuable data as to what transpires in its cells. Furthermore, the calorimetry of isolated tissues has recently been developed into a successful technic, so that the energy exchanges can be measured at the very seat of their genesis; and thus the caloric business of the entire individual can be investigated in the different departments, so to speak, that comprise our energy-transforming organization.

Precisely as the "heart-disease" of old is being subjected to careful analysis and classified into categories in which functional incoordination of beats, disease of localized muscular bundles or nervous transmission centers, vascular sclerosis or obstruction, myocardial incapacity, and what not, are all differentiated in diagnosis, so metabolism will soon no longer be the vague generalization that it has been. The newer devices of investigation and the special terminology employed have not yet become familiar to the ears of the clinician; but in time they will be mastered just as the findings of the electrocardiograph, of anaphylaxis, and of vaccine therapy and immunity are gradually being incorporated into our routine experiences.

By way of illustration of what is being accomplished in this field we may refer to a series of investigations conducted in Tangl's laboratory in Budapest.[1] By direct calorimetry Tangl[2] has estimated the work of the healthy kidneys, that is, the amount of chemical energy which is converted by the functioning of these organs into other forms of energy. In the animals investigated by him it amounts to about 8 per cent. of the total energy exchange during the resting condition. Here, then, is a concrete expression of the degree to which these secreting glands participate in the body's need for energy supplies. By way of contrast it is interesting to refer to the work of the spleen, which represents an organ entirely different in type from the kidneys. Extirpation of the spleen brings with it no appreciable, or at any rate no considerable, alteration in the respiratory metabolism of the individual[3]—a fact which we interpret to signify that the function of the spleen is of a decidedly different order from that of secreting structures of glandular nature.

The outcome of experiments under conditions of defective kidney function is very striking.[4] The work of the impaired, but still functioning, kidney is greater than that of a corresponding normal organ; it requires more oxygen and produces more carbon dioxid waste. In actual figures, an increase in energy transformation amounting to over 50 per cent. has been ascertained in some stages of nephritis. This increase in expenditure of energy under which the diseased kidney performs its work persists only so long as urine is abundantly secreted. When conditions arise in which pathologic defects have progressed to the point of partial suppression of the urine flow or to complete anuria, the kidney metabolism is no longer on a heightened plane. It may now even sink to levels below the normal for health. In other words, the increased energy expenditure of the diseased kidney ceases as soon as the power of secretion is profoundly impaired or lost.

---

[1] A group of interesting papers will be found in the Biochem. Ztschr., 1913, liii. No. 1/2.

[2] Tangl, F.: Calorimetrie der Nierenarbeit, Biochem. Ztschr., 1913, liii, 36.

[3] Verzár, F.: Die Grösse der Milzarbeit, Biochem. Ztschr., 1913, liii, 69.

[4] Cserna, S., and Kelemen, G.: Grösse der Arbeit kranker Nieren, Biochem. Ztschr., 1913, liii, 41.

Observations like the foregoing serve to place the energy aspects of the pathology of metabolism on a more comprehensible basis. They give an insight into kidney functions which no amount of microscopy or urinary analysis can replace.

Current Comment

SPECTACLES AND THE PANAMA EXPOSITION

The ubiquitous optician and the spectacle-vender have not overlooked the opportunity which the numerous world's fairs in recent years have afforded them of plying their trade. Like the lemonade and peanut vender at the county fair they have not failed to see that in these expositions lie chances for reaping a golden harvest on a widely expanded scale. It is understood that the management of the Panama Exposition at San Francisco intends to grant a spectacle concession. The possibility that harm to the eyes of those who purchase their wares will be caused through the totally unscientific work of these spectacle-venders has either not been understood by the exposition management or the swelling of the revenue has been allowed to outweigh any such considerations. In referring to this, *Collier's Weekly* says:

> Is the Panama-Pacific Exposition of 1915 going to taint itself at the outset by an alliance with quackery? Thus it would appear from the announced purpose of the management to offer over the counter the spectacle-selling concession of the enterprise. Protests, based on the ground that such procedure would be prejudicial to the eyesight of the public have thus far made no impression on the guiding spirits of the function as compared with the $60,000 or so to be gained.

The reply of President Moore of the exposition to one of these protests is: "If an official concession is granted at the exposition, it will only be to some business firm of high standing." This leads *Collier's* to remark:

> High business standing, doubtless. But of what professional standing or skill? Do the officials hold that protection of their guests' vision is a negligible consideration? Glasses fitted on purely concessionary or business principles may well ruin any eyesight. . . . The managers, on their own showing, take a purely commercial view of the transaction and utterly ignore the fact that better vision is not merely a matter of barter, but of professional skill and service. . . . Impaired vision for thousands of guests would be a dire aftermath to their fine enterprise.

The commercializing of a great exposition held in commemoration of the completion of one of the greatest works undertaken by men should at least not involve the danger of irreparable injury to the public who participate in it.

As *Collier's* says, "Obviously, to adopt the method of selling this permit to the highest bidder is to invite quackery," and quackery it will be whether the price be high or low.

THE PRICE OF RADIUM PREPARATIONS

The industrial journals report a marked reduction in the prices of radium preparations of late.[1] The total production of radium bromid per year is between 2 and 3 gm. In 1911 the radium preparations produced by the Austrian Radiumpraeparatefabrik amounted to 14.1 gm., containing 2.647 gm. of pure radium chlorid, valued at $214,900. Early in the present year radium bromid sold at $105 per milligram in Germany. In July, however, sales were made in Vienna at about half that price. As a reason for this decrease the fact is advanced that mesothorium, as well as radiothorium, has begun to be employed in place of radium, especially in medicine. Mesothorium more active than radium can be obtained at a cost of only $32 per milligram. Although the life of mesothorium is short, by mixing it with radium salts a long-lived preparation is said to be obtained.

THE FLUELESS GAS-HEATER

At this time of the year, when many feel that it is not cold enough to use the general heating-system of the house but is too cool to be entirely without heat, the use of portable gas- or oil-heating apparatus is a great convenience. Cleanliness and comparatively low cost of operation make this type of heating deservedly popular. Unfortunately many of these heaters are used without a flue-pipe to carry off the products of combustion. The use of such heaters is to be deprecated. This is especially true of those devices of low efficiency that make it practically imperative that the doors and windows be kept closed if the object sought—that of raising the temperature of the room—is to be attained. These heaters not only vitiate the air by consuming the oxygen and pouring forth the products of combustion into the room, but also put a premium on insufficient ventilation. The current issue of a high-class monthly magazine carries a full-page advertisement of a gas-heater that is specifically recommended for use in the children's play-room. It is advertised as "the ideal heat for the nursery," and in heavy type the claim is made that it "will not vitiate the air." Such advertisements are not only fraudulent; they are also dangerous. There may be times when one is willing to sacrifice health for comfort for a short time; when an increase of temperature in the room is sought even at the expense of vitiated air. When this is done with a full knowledge of possible dangers, it may not be too severely criticized. But to lead people to believe that any room can be heated healthfully for any length of time by means of flueless gas- or oil-heaters is dangerous doctrine. An efficient gas- or oil-heater with a flue attachment is an admirable piece of household apparatus; a flueless heater—except for the most temporary of uses, and then used with a full knowledge of the dangers involved—is an abomination.

---

DOES MILK CONTAIN LECITHIN?

The group of lipoid substances known as phosphatids or lecithins has long attracted the attention of physiologists because these fat-like compounds, containing both nitrogen and phosphorus in organic combination, appear to be a constant component of animal cells. They have formed a topic for discussion in connection with a great variety of biologic phenomena: absorption, growth, hemolysis, etc., in which phosphatids are currently believed to take a characteristic and more or less indispensable part. It is only a step further to inquire whether these compounds need to be furnished in the dietary or whether they can be constructed *de novo* as needed by the organism. Inasmuch as milk is the prominent if not the exclusive article of diet during an important period of growth, the question as to its content of phosphatids early received consideration. The very fact that the possible occurrence of lecithins in milk is debated is of itself suggestive that the quantity involved must at best be very small. The chemical methods for the detection of phosphatids are not ideal, to say the least. It is for this reason, doubtless, that some investigators, like the late Waldemar Koch, have affirmed, and others, like Schlossmann, have denied that milk contains them. The latest contribution,[1] based on apparently careful investigation indicates the complete absence of these ether-soluble phosphorus compounds in milk. If others have found positive results they are presumably due to substances other than lecithins of which milk may, for the present at least, be regarded to be devoid.

THE OCCURRENCE OF ALCOHOL IN THE TISSUES

Through the activity of the yeast-cell in the presence of glucose alcohol is formed. Is there anything analogous to this in the case of the animal cells that make up our tissues and organs? This question has often been debated; and the suggestion of close chemical relations between the fermentation initiated by yeast and certain aspects of the metabolism of carbohydrates in the animal body recurs from time to time. The possibility is further strengthened by the fact that muscle from freshly killed animals has more than once been reported on good authority as yielding traces of ethyl alcohol by distillation. The immediate explanation ventured has been that alcohol may be formed by the agency of micro-organisms in the alimentary tract. It may then be absorbed and distributed through the organism so that there need be no surprise if residual traces can be detected in the tissues at times. A. E. Taylor of the University of Pennsylvania has approached this phase of the theory advanced by examining the tissues of an animal in which bacterial processes within the digestive tube were excluded by complete removal of the tract. The operation is necessarily a difficult one; the circulation of the pancreas and the integrity of this gland must be maintained, and the animal must be kept alive long enough to permit the combustion of any traces of alcohol that might have been absorbed from the intestine prior to the operation. Even after this precaution small amounts of alcohol were still obtainable from the fresh tissues.[1] The implication thus obtained that alcohol may actually arise in metabolism offers nothing out of harmony with known biochemical fact and theory. It merely indicates one of the numerous possibilities, like lactic acid, formic acid, etc., exemplifying intermediary stages in the transformation of glucose by living organisms.

SANITARY MOTION PICTURE THEATERS

The majority of motion picture theaters are made by hastily equipping some store room ill suited to this purpose. The daily attendance in motion picture theaters in Chicago alone is estimated as close to 500,000. The total number of people throughout the country interested in this tabloid type of drama is enormous. In most instances the proper ventilation of such playhouses has been entirely neglected. Continually changing crowds of people are found in these places of amusement from 11 a. m. to 11 p. m. To neglect such a necessary question as that of ventilation and other sanitary measures in public places is almost criminal. In Chicago the Board of Health has undertaken an investigation of these theaters and is issuing certificates to the adequately equipped houses. Tests have been made by the ventilation department of the Board of Health which show that the air of a properly ventilated theater yielded but five colonies of bacteria on an exposed Petri plate, whereas, the air of an unventilated theater gave 250 colonies. The *Bulletin* says:

> "We shall go on fighting this menace until it is completely eliminated. We expect plenty of opposition from the short-sighted and ignorant classes of theater-owners, but the health interests of the many must eventually triumph over the money interests of the few. We fully recognize that when it's dollars against health it's an uphill fight for health.
>
> "If the people, whose health we seek to conserve, will lend us a fair measure of their moral support the fight will be won quickly.
>
> "Patronize only the properly ventilated theater.
>
> "Look for the Health Department's certificate."

FAITH WITHOUT WORKS

The Chicago newspapers recently gave space to the case of a young man who died under somewhat mysterious circumstances. After an all-night ride in taxicabs, the victim, who was a married man, reached home at seven o'clock in the morning half conscious. He died the following night. The coroner's autopsy indicated that death resulted from the effect of a drug. The wife testified that she realized that her husband was "dopy" when he reached home; she thought he was ill and "sent for a faith practitioner." When the "practitioner" arrived, the young man was totally unconscious and remained so until his death. From the newspaper accounts, then, it appears that a man suffering from the effect of some drug was given no treatment except that administered by a "faith practitioner." It is difficult for rational beings to understand the mental vagaries of those who place their reliance on "faith" practitioners. Had the young man in question been the victim of an automobile accident and been pinned beneath his machine, it is hardly conceivable that even a Christian Scientist would have expected the man to recover under "mental treatment." The first thing done would have been to remove the machine. As the unfortunate man had a poison in his body instead of an automobile on top of it, it seems to have been taken for granted that a "faith practitioner" was all that he needed. If the results of vicious fallacies were visited only on those that hold them, there would be nothing to say. Unfortunately, it is one of the conditions of life that suffering comes to the helpless and dependent almost as frequently as to those who deserve to suffer.

Medical News

CALIFORNIA

Personal.—Dr. H. G. Brainerd. Los Angeles. has been appointed a member of the commission to select a site and approve plans for the construction of a new state hospital in Southern California.

Physicians' Casualty Association Organized.—The Medical Men's Casualty Association has been incorporated with headquarters at Los Angeles. The following are directors: Drs. Edward J. Cook. A. D. McLeod. C. D. Hone. Francis E. Brown. Harry M. Voorhees. Harry G. McNeil. and Frank E. Detling.

Tuberculosis Camp.—San Diego has selected the location for a tuberculosis camp to which tuberculous patients who are wards of the county will be removed from their present quarters in the county hospital. The camp is to cost about $10,000 for its establishment and will accommodate about twenty-five patients.

Dispensary Opened.—The municipal nursing commission of Los Angeles has taken steps toward the opening of a free dispensary to be under the direction of the College of Medical Evangelists. The dispensary is to be under the supervision of the Health Commissioners and a nurse is to be on duty from 1 to 3 o'clock every afternoon.

Hospital Notes.—The cornerstone of the new St. John's Hospital at Oxnard was laid with impressive ceremonies September 23.——The contract has been let for the erection of a county hospital for Orange County near Santa Anna. at a cost of $44,944. The building is to be a two-story and basement structure. 48 by 92 feet. of reinforced concrete construction. ——It is announced that the new San Francisco Hospital will be completed and ready for occupancy by November 1. The buildings now being erected are to complete the group of tuberculosis and infectious disease buildings.——Mount Zion Hospital is being erected at the corner of Post and Scott streets, San Francisco. at a cost of $300,000.

COLORADO

Personal.—Dr. L. W. Ely. Denver. has accepted the chair of orthopedics in the Leland Stanford University. San Francisco. ——Dr. Ella H. Griffith. Denver. has won her suit for $3,000 against the estate of the late Hugh Butler for service rendered his deceased wife.

Reorganization of Medical School.—Under the reorganization of the School of Medicine, University of Colorado, the medical senate has been done away with. The executive committee consists of the dean. Dr. W. P. Harlow. chairman. and Drs. O. M. Gilbert. Boulder; Robert Levy. Edward Jackson. and W. A. Jayne. This committee has appointed three standing committees. the chairman of each of which is a member of the executive committee: hospital committee, W. A. Jayne; dispensary committee, Dr. Robert Levy; course committee, Dr. Edward Jackson. The dean is an ex officio member of all standing and special committees. The faculty (meaning the full professors) has been divided into the following groups: Surgery, Drs. R. W. Corwin. W. B. Craig, Leonard Freeman, Luman M. Giffin. H. G. Harvey, C. B. Lyman, George B. Packard, C. A. Powers, and E. J. A. Rogers; medicine, Drs. J. R. Arneill. S. G. Bonney, G. H. Cattermole, O. M. Gilbert, J. N. Hall. M. Kleiner, W. P. Rothwell, Henry Sewall. W. H. Sharpley. C. F. Shollenberger, C. B. Van Zant. and H. B. Whitney; eye, ear. nose and throat, Drs. Wm. C. Bane. Melville Black. John Chase, D. H. Coover, Edw. Jackson, J. M. Foster, Robert Levy; obstetrics and gynecology, Drs. T. M. Burns, C. S. Elder, W. A. Jayne. F. H. McNaught, and T. E. Taylor; fundamentals. Drs. C. T. Burnett. F. G. Byles. John Ekeley, C. Gillaspie, W. C. Mitchell. A. R. Peebles, E. B. Queal, J. C. Todd. H. E. Washburn. and R. C. Whitman; specialties, Drs. S. B. Childs. W. H. Davis, A. J. Markley, G. H. Stover, G. E. Neuhaus J. H. Pershing, H. T. Pershing, and N. Weist.

CONNECTICUT

New Officers.—Meriden City Medical Society, September 11: president. Dr. M. J. Sullivan (reelected); secretary and treasurer. Dr. David P. Smith.

Hospital Dedicated.—The new buildings of the Stamford Hospital were dedicated September 20. The hospital represents an outlay of $400,000. The buildings stand on a site of 12 acres donated by Albert Crane, and are of brick construction and fireproof, and include an isolation hospital for communicable diseases.

GEORGIA

Antituberculosis Association Receives Charter.—The Atlanta Antituberculosis and Visiting Nurses' Association was granted a charter September 5.

Medical Department Abandoned.—At a meeting held in Atlanta. September 6. by the management of the Southeastern University. it was decided to abandon at present the idea of opening a medical department of the institution this fall.

Personal.—Dr. Louis Hollander. Atlanta, has been elected superintendent of the Battle Hill Tuberculosis Sanatorium, Atlanta.——Dr. L. J. Chedel. city physician of Savannah. was seriously injured in an automobile accident September 19.

Information About Tuberculosis.—The State Board of Health has issued an educational bulletin telling of the history. the means of prevention. and the cure of tuberculosis. The board will examine sputum free of charge in its laboratory in Atlanta.

Medical Examiners Appointed.—Governor Slaton on September 24. appointed the following members of the Board of Medical Examiners: Drs. Jarrett W. Palmer. Ailey. Francis M. Ridley. La Grange, C. T. Nolan. Marietta, F. D. Patterson, Cuthbert. representing the regular school; Drs. C. M. Paine. and R. E. Hinman. Atlanta, representing the homeopathic school. and Drs. A. F. White. Flovilla, and A. Fleming. Waycross. representing the eclectic school.

ILLINOIS

Personal.—Dr. John Ross. Pontiac, has succeeded Dr. James A. Marshall as physician to the Illinois State Reformatory. ——Dr. Isaac Moore. Alton, is reported to be seriously ill as the result of a cerebral hemorrhage.

Tuberculosis Cottages to Be Built by County.—Vermilion County has arranged to provide for its tuberculosis patients by the erection of two cottages at the County Home. The buildings are to be completed before December.

Anti-Tuberculosis League Organized.—At a meeting held in Mendota recently. the LaSalle County Anti-Tuberculosis League was organized. Drs. E. P. Cook, Mendota. Benjamin J. Nauman. Peru. and William Schoenneshofer, Lostant, are vice-presidents of the league.

Chicago

New Year of the Medical Women's Club.—The Medical Women's Club held its first meeting and dinner of the year at the Chicago College Club, October 8.

Out-Door School Plan.—An out-door school for children affected with tuberculosis is to be erected on the roof of the Parish House of Grace Episcopal Church.

New Psychopathic Hospital.—The Cook County Detention Hospital has been dismantled to make room for a new psychopathic hospital with accommodation for more than two hundred patients. For the present, patients are being cared for in a building across the street from the old detention hospital.

Personal.—Dr. C. St. Clair Drake has been elected president of the Town and Country Club.——Dr. Ludwig Simon sailed from San Francisco, October 7, on a six months' trip around the world.——Dr. and Mrs. E. Fletcher Ingals and daughter and Dr. and Mrs. G. E. Fosberg have returned from Europe. ——Dr. B. M. Linnell fractured his arm while cranking his automobile, October 6.

American College of Surgeons.—Dr. Franklin H. Martin, general secretary of the American College of Surgeons, asks us to announce that on the evening of Nov. 13, 1913, will be held the first formal meeting for the conferring of fellowships on the members of the American College of Surgeons. Sir Rickman Godlee, the president of the Royal College of Surgeons of England, will deliver the principal address, and Dr. J. M. T. Finney the presidential charge.

Clinical Congress of Surgeons of North America.—The fourth annual session of the Clinical Congress of Surgeons of North America will be held in Chicago, Hotel LaSalle, November 10 to 15. On each evening except Saturday, scientific sessions will be held. On Tuesday, Thursday and Friday evenings there will be separate meetings for those specially interested in surgery of the eye, ear, nose, throat and mouth. Prominent men from abroad have been invited. The preliminary program may be had from the general secretary, Dr. Franklin H. Martin, 31 N. State St., Chicago.

MARYLAND

Births Exceed Deaths.—Interesting statistics in the report of the Baltimore Health Department for the last month show that the births exceeded the deaths by 432, the deaths totaling 792 and the births 1,224, the largest number of any month this year. On the basis of an estimated population of 575,204, the percentage of deaths was 16.45 and that of births 25.45 per thousand. There were 526 marriages reported.

Centennial of Foundation of Library.—The beginning of the present term of the Maryland University is the one hundredth anniversary of the founding of the library by Dr. John Crawford. The library now contains 18,000 volumes, among them some rare editions, especially those bequeathed by Dr. Crawford, who was probably the first physician to arrive at any remarkable results in regard to the conveyance of contagious diseases by mosquitoes.

Report of Mental Hygiene Committee.—The Mental Hygiene Committee of the Maryland Psychiatric Society, Dr. Adolf Meyer, chairman, held a meeting on October 7 and received the report of Dr. W. B. Cornell, the executive secretary. In the nine months of the committee's existence, over 200 cases have been handled. The work of the committee deals both with preventive and after-care cases and is in close touch with all social service agencies, as well as all the hospitals for the insane in the state.

Baltimore

Personal.—Dr. J. Whitridge Williams has returned from Watch Hill, R. I., where he spent the summer.——Drs. Lewellys F. Barker, Thomas H. Buckler and William H. Welch, have returned from Europe.——Dr. Brice W. Goldsborough recently underwent an operation at the Hervar Kelley Sanatorium.

Ask Increased Appropriations.—Mercy, Maryland General, St. Joseph's, St. Agnes', Franklin Square and Maryland Homeopathic hospitals, have applied to the Board of Estimates for an increased appropriation from Baltimore City. The money appropriated is for the maintenance and treatment of "free patients," many of whom have to be turned away for lack of funds.

NEW YORK

State to Build Antitoxin Laboratory.—The State Health Board has decided to purchase property at Guilderland, near Albany, on which to erect an antitoxin laboratory for the State Department of Health.

Want Health Home Kept Open.—An effort is being made to raise funds sufficient to keep the Health Home for Working Girls at Santa Clara in the Adirondacks open during the winter months. Many girls suffering from tuberculosis have appealed for care until late into the fall.

New Officers.—Medical Society of the State of New York, Seventh District Branch, at Sonyea, September 25: president, Dr. William T. Shanahan, Sonyea; secretary, Dr. John F. Myers, Sodus.——Eighth District Branch: president, Dr. Arthur G. Bennett; secretary, Dr. Carl Tompkins, both of Buffalo.

Hospital News.—The Montgomery County Tuberculosis Hospital near Amsterdam was officially opened to the public September 20.——The contract for building the Children's Tuberculosis Hospital at Buffalo has been awarded, and the acting mayor has approved the action of the common council regarding the issuance of bonds.——It has been decided not to open the winter tuberculosis camp near Dunkirk this winter.

Memorial Meeting of Faculty.—At a meeting of the faculty of the College of Medicine of Syracuse University September 25, Dr. A. B. Miller read a memorial of Dr. Albert S. Hotaling, and Dr. Henry L. Elsner eulogized the work of the late Dr. Nathan Jacobson.——Dr. Eugene W. Belknap has been nominated professor of obstetrics, vice Dr. Hotaling, and Dr. L. C. Ransom has been nominated instructor in clinical chemistry and microscopy.

Personal.—Dr. William D. Johnson, Batavia, fell from a ladder September 24, breaking his left leg just above the ankle.——Niagara Falls Academy of Medicine gave a dinner September 25 in honor of Dr. Carl G. Leo-Wolf, who is about to leave for Germany. Dr. Leo-Wolf was presented with a black walrus traveling-bag.——Dr. John R. Ross of the St. Lawrence State Hospital, Ogdensburg, has been appointed first assistant physician at the Dannemora State Hospital.

New York City

Leaves Large Estate.—The will of the late Dr. Oliver Livingston Jones was filed for probate September 11. It disposes of an estate valued at $10,000,000.

Evolution.—While the registration at Columbia University is 200 in excess of that of last year, being 5,930, the School of Medicine has only 289 students as compared with 302 for 1912.

Issuance of Birth Certificates.—During the eight days immediately preceding the opening of the school term, the Bureau of Records of the Department of Health issued 20,834 copies of certificates of birth to children about to enter school.

New Columbus Hospital.—Plans for the new Columbus Hospital have been approved by the State Board of Charities and the Building Department and the new building on East Twenty-Sixth Street will be begun in a few weeks. The building is to be ten stories high, will accommodate 300 patients and will cost $150,000.

Infant Mortality Rate Again Lowered.—According to the records of the Babies' Welfare Association, the last two weeks in September show a considerable decrease in infant mortality as compared with the corresponding period of last year. During the last two weeks in September there have been seventeen fewer deaths than occurred during the corresponding two weeks of 1912. Up to this time there have been 358 fewer deaths among infants this year than during 1912.

Harvey Society Lectures.—The first lecture of the ninth course of Harvey Society lectures was delivered on October 4 by Prof. A. D. Waller, University of London, entitled "A Short Account of the Origin and Scope of Electro-Cardiography." The second lecture of the course will be delivered on the evening of October 18 at the New York Academy of Medicine by Prof. Adolph Schmidt of the University of Halle on "Severe Anemia in Gastro-Intestinal Diseases."

East Side Blames City for Typhoid Epidemic.—The East Side Protective Association held a meeting on September 27 at which ways and means of stemming the tide of typhoid fever were discussed. A protest was sent to the mayor demanding a more rigid enforcement of the Sanitary Code. The protest called attention to the fact that fruit merchants feel that fruits unfit for food and other decayed food can easily be disposed of in this district, and that it is the duty of the city to see that the people are protected from the greed that places no value on life.

Personal.—Dr. Lucius W. Hotchkiss met with an automobile accident at Troy Hills, N. Y., on September 28. He sustained a fracture of the arm near the shoulder and a number of severe cuts about the head. His wife and two children, who were with him, were also injured.——Dr. Robert L. Morrison, surgeon-in-chief of the Williamsburg Hospital, and Dr. Emil Boehm, a young surgeon attached to the second division of Bellevue Hospital, are seriously ill with blood poisoning, the result of slight wounds sustained while performing operations. ——Dr. Walter Beusel, sanitary superintendent of the Health Department, has resigned.

New Laboratory at Otisville.—The new laboratory at Otisville Tuberculosis Sanatorium has begun its work. Under the direction of Dr. A. McNeil, two bacteriologists, one laboratory assistant and two helpers are now engaged in carrying out research work. The two bacteriologists are Drs. H. A. Hatfield and I. Abrahamson. At the present time the refining of antitoxin is being done at Otisville and experimental work in complement fixation in tuberculosis has been begun. The Department of Public Charities has recently placed at the disposal of the Tuberculosis Admission Bureau the use of a commodious omnibus for the transfer of Otisville patients and their baggage from the bureau to the Erie Railroad Depot.

The Cost of Aliens to Bellevue and the Allied Hospitals.—A report recently submitted to the mayor by the commissioner of accounts shows that during the year 1912 there were 57,422 persons treated in the wards of Bellevue and the Allied Hospitals and that an inspection of the records of these patients, in 11,334 cases treated in October, November and December of last year, showed that 671 had been less than three years in this country. If this ratio were applied to the three years, 1910, 1911 and 1912, approximately 9,879 aliens not citizens of this country were treated without charge. It is estimated that the cost for such treatment amounted to $208,446. The inclusion of aliens who have been in this country for more than three years would considerably augment this sum The board of trustees of Bellevue and the Allied Hospitals recommend that negotiations be opened with the proper authorities at Washington with a view of relieving New York City from the unjust share of this federal burden and that a history be prepared of each dependent alien in these institutions with a view to deportation if the circumstances warrant such action.

NORTH CAROLINA

Will Surrender Lease of Hospital.—Dr. Eugene M. Yount, Statesville, announces his intention of surrendering the lease of Billingsley Hospital to the municipality, January 1 next. It is expected that the city will reopen the institution as a general hospital, open to the profession and public.

Personal.—Prof. William DeB. MacNider, professor of pathology in the University of North Carolina, was the guest of honor at a banquet of the Mecklenburg County Medical Society in Charlotte, October 3, at which he gave an address embodying the results of his recent research on renal circulation and its relation to the diseases of the kidney.

Annual Examination of Policy Holders.—The Southern Life and Trust Insurance Company, Greensboro, has announced a permanent policy of offering each of its policy-holders an annual examination made by physicians from the home office to enable the insured early to apprehend any malady and thus be better enabled to prevent the development of disease or to check it in an early stage.

Typhoid in Charlotte.—On account of the report of the city health officers of Charlotte that 74 per cent. of the cases of typhoid fever in the city this season had occurred in persons using open wells and not city water, and the report that more than 90 per cent. of the specimens of well water examined had shown more condemnation than the raw water from the Catawba River, the Charlotte Board of Health has ordered disinfection and closing of the open wells in the city.

Hospital Staff Elected.—The board of managers of the Mission Hospital, Asheville, announces that the following staff has been elected: Drs. M. H. Fletcher, Charles S. Jordan, Lewis B. McBrayer, Marion C. Millender, Porter B. Orr, Paul H. Ringer, Arthur T. Pritchard, Joseph B. Greene and Arthur W. Calloway. Drs. Lewis W. Elias, William P. Herbert, O. F. Eckel, J. L. Adams, Franklin W. Griffith and Martin L. Stevens were elected as the adjunct staff. Dr. William L. Dunn was elected dean of the Nurses' Training School.

PENNSYLVANIA

New Officers.—Tri-County (Dauphin, Lebanon, Lancaster; Fourth Censorial District) Medical Society, at Lancaster, August 28: president, Dr. Joseph R. Beckley; secretary, Dr. George R. Pretz, both of Lebanon.

Small-Pox at Coatsville.—As the result of a visit of a traveling salesman for a brewery firm, suffering with small-pox and mingling with many people, nine families of Coatesville and Parkersburg have contracted the disease. Citizens of both towns have been advised to be vaccinated.

Personal.—Dr. Harry B. Burns has succeeded Dr. E. R. Walters as Director of Public Health of Pittsburgh. Dr. Walters has been appointed delinquent tax collector of Allegheny County.——Dr. Watson L. Savage, director of physical training in the public schools of Pittsburgh, has resigned to take charge of the New York Normal School for Physical Education.——Dr. Charles M. Strickler, Lebanon, is seriously ill with peritonitis.——Dr. George Hay, city physician of Johnstown, is ill in the municipal hospital with scarlet fever.——Dr. J. K. Weaver, Norristown, has been elected surgeon-general of the Grand Army of the Republic.——Dr. Charles W. Youngman, Williamsport, has been elected president of the Antees Fort Memorial Association.——Dr. John C. Price of Scranton, Pa., has been appointed chief medical inspector of the Department of Labor and Industry.

Philadelphia

Additions to Hospital.—Extensive additions are shortly to be made at St. Mary's Hospital, which will more than double the capacity of the institution.

Free Clinical Courses.—The Hughes-Wilson courses on the heart and lungs, given annually at the Philadelphia Hospital, began September 29. This course is open to the medical profession without charge.

Baby Show at City Hall Closes.—The baby-saving show, which for the last four months has been on exhibition to the public at City Hall, closed October 2. Since the opening, there were more than 400,000 visitors.

Physical Defects of Schoolchildren Costly.—According to statistics compiled by Dean E. C. Kirk, of the University of Pennsylvania Dental Department, lack of attention for schoolchildren costs Philadelphia $130,000 yearly.

New Superintendent.—George G. Signor, for eight years superintendent of the Medico-Chirurgical Hospital, has resigned to take charge of the Eastern Pennsylvania State Institute for the Care of Feeble-Minded and Epileptics, Pottstown.

Eye Dispensary at School.—A branch of the eye dispensary of the Philadelphia Department of Public Health and Charities for the examination and treatment of the eyes of schoolchildren has been established at the Southwark School, and is in charge of Dr. W. J. Ryan.

To Raise Fund for West Chester Hospital.—Officials of the Chester County Hospital have inaugurated a campaign to raise $80,000 for the erection of additions to the present institution. The fund will be used to erect and equip a new and modern operating room, power house and laundry, sun parlors and diet kitchens.

New Children's Hospital.—Work was begun September 29, on the foundations for the first of the group of buildings to be constructed at Eighteenth and Fitzwater Streets for the Children's Hospital. This will be the dispensary, and it will be at the northeast corner of Eighteenth and Fitzwater Streets. This new group of buildings will take the place of the present Children's Hospital on Twenty-Second below Walnut Street, which has been outgrown. They will occupy the site of the old Williams lumber yard on Eighteenth, from Fitzwater to Bainbridge Street, and the houses 1715 to 1721 Fitzwater Street.

Typhoid Epidemic Not Abated.—There is no abatement in the epidemic of typhoid fever, the number of new cases reported during the week reaching 54, an increase of 11 over the previous week. George C. Whipple, professor of Sanitary Engineering at Harvard University, and F. Herbert Snow, chief of the sanitary engineering department of the State Board of Health, began investigations here on September 29. The United States Health Service is also taking a part in the investigation and Dr. W. G. Stinson, U. S. P. H. S., together with Chief John A. Vogelson, of the Bureau of Health, and Carlton A. Davis of the Water Bureau, examined the river boats and piers on October 1.

Personal.—Dr. Robert C. Parish has been appointed medical supervisor of public schools vice Ralph C. Spangler, resigned.——Dr. Morris Jastrow has been invited to give a lecture before the Royal Society of Medicine in London, on "The Medicine of Babylon and Assyria." Jastrow sailed for England, September 27.——Dr. L. B. Moore, ambulance physician at the Presbyterian Hospital, was painfully injured in a collision between the ambulance and a street-car, September 9.——Dr. E. B. Hodge, a member of the visiting staff of the Presbyterian Hospital, Philadelphia, had a narrow escape from death on October 4, when his motor-car was caught between two trolley cars and smashed to pieces on the Chestnut Street bridge. Dr. Hodge was buried beneath the wreckage but escaped with slight bruises.——Dr. George Morrison Coates has been elected surgeon to the ear, nose and throat department of the Pennsylvania Hospital, as a colleague of Dr. Francis R Packard.

GENERAL

Special Train to Academy Meeting.—A special train has been arranged for the accommodation of those who wish to attend the annual meeting of the American Academy of Ophthalmology and Oto-Laryngology at Chattanooga. The train will leave Chicago October 24 by way of the Chicago and Eastern Illinois Railroad to Nashville, and the Nashville, Chattanooga and St. Louis Railway to Chattanooga, arriving at 3:42 p. m., October 25.

Railway Surgeons to Meet.—The annual meeting of the National Association of Railway Surgeons will be held at the Hotel Sherman, Chicago, October 15 to 17.——The seventh annual meeting of the Minneapolis, St. Paul and Sault Ste. Marie Railway Surgical Association will be held at the Hotel Pfister, Milwaukee, December 4 and 5.——Dr. John B. Murphy will deliver the oration on surgery, on "Fractures in the Neighborhood of Joints," and Gov. McGovern of Wisconsin will deliver a discourse on the "Workmen's Compensation Act."

Bequests and Donations.—The following bequests and donations have recently been announced:

St. Joseph's Hospital, Yonkers, $25,000 toward the enlargement fund subscribed by Alexander Smith Cochran.

Mount Sinai Hospital, New York City, $5,000, and Infants Summer Hospital, Lake Ontario, $1,000, by the will of Abram N. Stein.

University Hospital, Philadelphia, $5,000, by the will of Fanny H. Dickson.

Charity Hospital and Episcopal Hospital, Philadelphia, contingent bequests of $25,000 each, by the will of Mrs. Helen E. Payne.

University Hospital, Philadelphia, one-third, and Pennsylvania Epileptic Hospital and Colony Farm in Chester County, two-thirds of a contingent bequest of $130,000 by the will of Mrs. Anna F. Francine.

Wyandotte City (Mich.) Municipal Hospital, the residence of Mrs. Fred Ginzel with the provision that the state will name the institution after her deceased son.

Hahnemann Hospital, Chicago, $100,000 for the building fund donated by William Wrigley.

Abington (Pa.) General Hospital, $135,000, donated by George W. Elkins.

Massachusetts General Hospital, Boston, $30,000 for free beds; Childrens Hospital, Boston, $25,000; Convalescent Home of the Childrens Hospital, $25,000; Massachusetts Charitable Eye and Ear Infirmary, Industrial School for Crippled and Deformed Children and Boston Asylum and Reform School, Thompson's Island, $10,000 each, *by the will of Harriet O. Cruft.*

Alvarenga Prize.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about $180, will be made on July 14, 1914, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be on any subject in medicine, but cannot have been published. They must be typewritten, and if written in a language other than English should be accompanied by an English translation, and must be received by the secretary of the college on or before May 1, 1914. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. It is a condition of the competition that the successful essay or a copy of it shall remain in possession of the college; other essays will be returned on application within three months after the award. Further information may be obtained on application to Thomas R. Neilson, M.D., Secretary, 19 South Twenty-Second Street, Philadelphia, Pa., U. S. A.

CANADA

Quarantine Building Site Approved.—Dr. F. Montizambert, director-general of public health, while on his annual tour of western Canada, approved of the site for a new quarantine building at the William Head Station at a cost of $45,000.

Epidemic Warning.—The epidemic of infantile paralysis which broke out in Montreal about five weeks ago is now waning. The cases were promptly reported to the medical officer of health. There were about twenty-five cases altogether.

Medical Museum Trip Successful.—Dr. Maude Abbott has returned to Montreal from Italy. As secretary of the International Association of Medical Museums, Dr. Abbott was successful in establishing a branch in Italy. Her visit to Europe extended over three months.

Reporting Venereal Diseases.—The Social Service Council of Canada has adopted a resolution calling for the reporting of venereal diseases to the medical officers of health, and providing that no one be granted a marriage license until the contracting parties present medical certificates of normal mentality and freedom from venereal diseases.

The Licensure of Osteopaths and Chiropractors.—In the annual report of the Manitoba Medical Council the statement is made that each year the council has had to fight legislation to license osteopaths and chiropractors. Thus far the council has prevented legislation giving legal status to these people. The registration fee of the Manitoba council has been reduced from $125 to $100.

Hospital News.—Plans for a new general hospital at Kootenay, B. C., have been approved by the Hon. Dr. H. E. Young, provincial secretary. The estimated cost is $75,000, and provision is to be made for fifty-five patients.——A new hospital at Ashcroft, B. C., has just been opened. It cost $12,000 and has accommodation for fifty patients.——The plans for the new hospital at Victoria, B. C., call for an expenditure of $450,000 for the mortuary and pathologic buildings alone. The new hospital is to have in addition four ward buildings, an administration building and a service department building. All the buildings will have capacious roof gardens.——The government of British Columbia will assist the governors of the new hospital at Alberni, B. C., in clearing that institution of all debts.——The new wings of the Winnipeg General Hospital, which cost, exclusive of furnishings, $650,000, were formally opened on September 29. The accommodation in the Winnipeg General Hospital is now 478 beds.

LONDON LETTER

(From Our Regular Correspondent)

London, Sept. 27, 1913.

Vital Statistics

A report has just been issued by the registrar general on the vital statistics for the year 1911, and contains several interesting facts. The birth-rate was 24.4 per thousand of the population and 2.8 below the average for the preceding decennium and the lowest on record. Provisional figures for 1912 indicate a further fall of 0.6. The death-rate was 14.6 per thousand, or 0.8 below the average of the preceding decennium; this is 1.1 per thousand above that recorded in 1910, which was the lowest on record. The provisional rate for 1912 is, however, only 13.3. Marriages were in the proportion of 15.2 per thousand, being 0.3 below the average of the preceding decennium but 0.2 above that in 1910, which in turn was 0.3 over the rate in 1909. The provisional figures available for 1912 show a further increase of 0.8. Infantile mortality, owing largely to the abnormal heat of the summer, was 130 per thousand births, or twenty-five more than in 1910 and the highest recorded since 1906. The provisional rate for 1912, however, is only ninety-five, so that in spite of interruptions there has been on the whole a fall in the mortality. As to individual diseases, measles and diarrheal diseases showed more than the average mortality. On the other hand, the death-rate from scarlet fever was the lowest recorded. That for whooping-cough was the lowest except the rate of 1910; that for diphtheria and croup the lowest except for 1910, and that for typhoid fever the lowest except for 1909 and 1910. The rates for bronchitis and all forms of tuberculosis were lower than in any previous years except 1910. On the other hand, the death-rate from cancer was higher among both males and females than in any preceding year.

Outbreak of Small-Pox in Australia

An extensive outbreak of small-pox has occurred in New South Wales and furnishes an object lesson, much needed in this country, of the pernicious effect of the antivaccinationists. For many years that community has been practically unvaccinated, and yet it is in constant communication with the almost perpetually infected ports of eastern Asia. A strict quarantine system has proved very effective, however, for many years. Indeed, with the exception of Victoria the vaccination laws are practically a dead letter in all the Australian colonies. In the period of thirty years, from 1881 to 1910, only 108 deaths from small-pox have been recorded in Australia, and many of these occurred in new arrivals in quarantine. So successful has the quarantine system been that from want of experience many of the local physicians missed the diagnosis of the milder cases of the present epidemic. It may be remarked that owing to the same cause many of the cases of small-pox which occurred in the last epidemic in London, about ten years ago, were not diagnosed by the physicians. It seems that the disease in the present epidemic was introduced from New Zealand, where it had been brought by a Mormon missionary suffering from such a mild form that he baffled the quarantine officers. He infected the Maori population among whom he was working. In Sydney cases began to occur last April and were diagnosed as chicken-pox. In June a patient was admitted to the Sydney Hospital and the case was correctly diagnosed by a dermatologist. He was overruled by men of less experience, however, and only after great difficulty succeeded in getting the patient isolated. From that time greater care was taken, and in July it was at last officially announced that sixty cases of small-pox were recognized in Sydney. Every facility was at once provided for the vaccination of Sydney residents, of whom nine-tenths had never undergone the operation. Persons were vaccinated in large numbers. Unfortunately many of them were very ill after the operation with symptoms resembling influenza, and as they had been told that the operation was perfectly harmless disappointment resulted and vaccination fell into disfavor. This result appears to have been partly due to the inexperience of the operators, who used the lymph too freely. The total number of cases of small-pox recorded in New South Wales up to August 11, was 458. Nine of the patients had been vaccinated in infancy, but none of the others had been vaccinated. Such a scare has now been created that vaccination is made compulsory and quarantine is enforced more strictly than ever.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Sept. 26, 1913.

Vocational Mortality

Dr. Jacques Bertillon, formerly chief of the Paris department of statistics, has published a study of mortality in the different vocations, dividing them into five groups according to their particular causes of death: employments exposing the workman to (1) alcohol, (2) lead-poisoning, (3) organic waste, (4) the weather, and (5) confined positions. These five groups are subdivided into a hundred distinct vocations. The principal causes of mortality prove to be alcoholism, diseases of the lung, heart, liver and nervous system, diabetes, suicide and accidents.

Most healthful are those vocations carried on in the open air, provided they permit movement: those restricting freedom of movement, though carried on in the open air, are harmful. Trades exposing the workmen to alcohol and to lead-poisoning are the most dangerous.

Mortality is lowest among railway enginemen, wood-sawyers, teachers, attorneys and clergymen. It is nearly as low among physicians, pharmacists, architects, lawyers' clerks, mail and telegraph employees, commercial travelers, grocers, fruiterers, hatters, booksellers, hardwaremen, watchmakers, weavers, tanners, masons, road laborers and servants.

Mortality is higher than the general average among public officers, office clerks, street-railway employees, gas-workers, sellers of fish and poultry, jewelers, cloth merchants, saddlers, bakers, millers, butchers, curriers, rope-makers, cabinet-makers, carters, roustabouts and sailors.

Mortality is highest among day laborers, stevedores, miners, stone-cutters, tradespeople, coachmen, grooms, foot-boys, jockeys, petty shop-keepers, printers, blacksmiths, tilers, glass-makers, messengers, cutlers, chimney-sweeps, barbers and musicians.

Suicide is encountered in nearly all vocations but is rare among clergymen, officers, railway, mail and telegraph employees, shipbuilders, sawyers, employees in gas-works and booksellers. It is quite rare among tanners, masons, farmers, road-builders, boatmen, fishermen, wheelwrights and miners. It is met comparatively often among grocers, hardwaremen, cloth-merchants, coopers, weavers, blacksmiths, glass-makers, cabinet makers, tobacconists, notaries and lawyers' clerks, teachers, architects, sailors and gamekeepers. Suicide is frequent among brewers, tilers, petty shop-keepers, cutlers, hatters, barbers, tradespeople, clockmakers, jewelers, domestics, dairymen, sellers of fish and poultry, gardeners, commercial travelers, attorneys, physicians and pharmacists. All these vocations show a frequency of suicide above the average, but the highest suicide-rate is found among saloon-keepers, the servants of retail storekeepers, chimney-sweeps, butchers, fruiterers and musicians.

Treatment of Mushroom Poisoning by Abscess of Fixation

Long ago Fochier of Lyons proposed for certain generalized infections (pneumonia, puerperal fever, etc.), a treatment which bears his name to-day and consists in the production by the subcutaneous injection of essence of turpentine of an aseptic abscess of fixation. Carles of Bordeaux has shown that in the pus of these abscesses are sometimes found the organisms which have caused the disease against which this therapy has been directed. Lesieur also has shown that in certain cases of typhoid virulent bacilli of Eberth are found in the abscess of fixation. In addition to microbes, this pus has been found to contain toxic substances like lead or mercury in those patients affected with plumbism or mercurial poisoning.

Dr. A. Pic, professor of therapeutics at the Faculté de médecine de Lyon, has been led by these facts to believe that the toxic agent causing poisoning by mushrooms containing phallin (a toxalbumin acting like a microbe toxin) will be found fixed in the pus of the abscess. After observing for several years many cases of mushroom poisoning at Trévoux, Ain, he applied the method of Fochier to patients who were yet alive at the first examination, with the result that of twenty-three treated, nine died and the others recovered, a mortality of only 39 per cent., in contrast to 86.8, which is the usual mortality. Out of thirty-eight cases of phallin poisoning in France in recent years, thirty-three were fatal.

Pic and Martin conclude that the abscess of fixation is a therapeutic agent of the first order in those terrible intoxications due to the *Amanita phalloides.*

Sale of Alcohol to Railway Employees Forbidden

The management of the state railways has forbidden the sale of alcohol or alcoholic drinks to any one employed by the railways. Railway officers are asked to keep watch to prevent any employee leaving his work and going to a saloon during his working hours. A similar watch is recommended to prevent any one from bringing alcoholic drinks onto railway property.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Sept. 19, 1913.

Personal

Professor Gaffky, director of the Institute for Infectious Diseases, retires from his position October 1. His successor will probably be Professor Loeffler of Greifswald. Gaffky has been tired of his work for a long time, in view of his age, 63, and intends to give himself a complete rest and take a permanent vacation at his native city, Hanover. It will excite surprise among many that Loeffler at nearly the same age should change his residence, but Loeffler has for a long time expressed the natural wish to leave the small university town and seek a wider sphere of activity. This desire has undoubtedly grown stronger since the death of his wife a few years ago.

The seventieth birthday of the noted Berlin ophthalmologist, Prof. Julius Hirschberg, was observed September 18. Hirschberg's name is closely connected with the progress of modern ophthalmology. After he attracted the attention of Albrecht von Graefe in the Berlin municipal cholera hospital he stood in close relation to the father of ophthalmology, and helped with his own work to raise the treatment of the eye to the rank of an independent medical science. He was born in Potsdam, studied in Berlin, and was then for two years an assistant of Virchow. From 1866 to 1868 he was Graefe's assistant. Then he founded his own institute for ophthalmology, which has been in existence for over forty-three years, and in the records of which hundreds of thousands of patients are inscribed.

In 1870 Hirschberg began to teach in the Berlin university: after nine years he became professor extraordinary, and in 1900 he was made regular honorar-professor. His scientific work, however, was not devoted exclusively to medicine. Even when privat-docent he took up the study of higher mathematics and physics, and worked in the laboratory of Helmholtz. As a result, the scientist was capable of writing on the mathematical principles of medical statistics. Scientific journeys took him into almost all parts of the world, and his diaries on these journeys are very stimulating; especially the description of his journey around the world, and his books on Tunis, Egypt and "From New York to San Francisco." The ancient world attracted his especial interest. He has given a report of his journeys in Greece, and published a glossary and commentary on Aristophanes following the comedies of the Greek classic author almost line for line with well-chosen explanations and translations of all the expressions and idioms that are difficult to understand.

But Hirschberg's monumental work of recent years is the history of his special science, for which he also compiled a model dictionary. In 1899 he published the history of ophthalmology in ancient times following it by the history of this science among the Arabs. With two noted Arabian collaborators, he compiled the material with reference to Arabian ophthalmologists in a special work in two parts. Hirschberg followed this with the history of ophthalmology in the middle ages and into the beginning of modern times, describing its renaissance in the eighteenth century. This volume has been translated into French. The final volume, which appeared last year, treats of the ophthalmologists of Germany in the first half of the nineteenth century. What Hirschberg has accomplished in practical ophthalmology with his literary publications may even now be estimated. A selection of his works was published a few days ago.

I shall further call attention to his articles which appeared in 1869 on medullary cancer of the retina, on the electromagnet in ophthalmology for removal of splinters of iron from the interior of the eye, which has rendered innumerable operations unnecessary, his work on the treatment of myopia, and his articles on the statistics of blindness, on tumors of the eye, and the measurement of the field of vision. Hirschberg is the founder of and from 1877 to date has been the editor of the *Zentralblatt für Augenheilkunde.* Many ophthalmologic societies have elected him an honorary member and he is the president of the Berlin Ophthalmologic Society, corresponding member of the Paris Académie de médecine and an honorary doctor of the University of Athens. On his seventieth birthday, a portrait bust of Hirschberg was installed in his clinic.

As I have already mentioned, Privat-Docent Otto, the director of the Institute for Experimental Therapy established by the Kaiser Wilhelm-Gesellschaft, has been placed in charge of a department in the Institute for Infectious Diseases.

The chair of hygiene at the Bonn university left vacant by the call of Professor Kruse to Leipsic, will not be filled for the winter semester. Privat-Docent H. Selter will be in temporary charge of the hygiene institute.

For the first time, a woman physician has recently been appointed medical inspector for the Berlin public schools.

The Rudolf Virchow Building

At its session, September 18, the city council ratified the proposition of the city government, and provided: 1. For carrying on the Rudolf Virchow-Haus for five years succeeding Oct. 1, 1914, the Berlin Medical Society is granted a yearly stipend of $2.500 (10.000 marks) from the city treasury. 2. The city government is empowered, under conditions to be determined between the city government and the society, to grant the society for the building of the house a sum of $250,000 (1,000,000 marks) to be loaned for ten years at 4 per cent. interest. Thus the Berliner medizinische Gesellschaft is now relieved from all difficulty in this important matter, and the building can be begun at once.

Progress of Hygiene in the German Army

For some time courses in cooking have been held in the Prussian army, attended by officers, medical officers and noncommissioned officers. They are given in Berlin and are intended to instruct in the proper inspection of raw material and the preparing of foods. In the garrisons special windows have been constructed for giving out the food from the company kitchens by which the cleanliness in the rooms has been markedly increased. Quite generally also a set of measures has been adopted to carry out the modern principles of sanitation. For instance, a special waiting-room for the relatives of sick soldiers has been instituted in the large hospitals, and, in addition, the now quite extended provision for medical treatment of the members of families of the subordinate officers has had the result that special rooms for the dental polyclinic treatment of members of families and especially the wives of the non-commissioned officers have been established. Furthermore, the effort has been made to provide suitable opportunities for bathing in the garrisons and at the exercise fields for the troops where these are lacking.

The cooperation of all the factors favoring health has led to the result that the condition with reference to venereal diseases is much more favorable now as compared with other armies. According to the latest special statistics, 11,466 cases occurred annually, or 20.8 per thousand. In the French army the number was 24.4, in the Austria-Hungarian, 54.7, and in the British army 65.9 per thousand, that is, three times the number of infections compared with ours. As an example of the efforts now being made to reduce the morbidity among the soldiers, attention is being paid to the so-called "Exerzierfuss," and other foot troubles resulting from overuse in marching. The success of these efforts is indicated by the lowered percentage of such affections. Until 1901 there were annually about 28.4 per thousand afflicted with foot troubles, and now only 23.3 per thousand.

Marriages

CHARLES WILLIAM LOUIS HACKER, M.D., Albany, N. Y., to Miss Larry Diefendorf of Fort Plain, N. Y., at Watervliet, N. Y., September 17.

REUBEN H. LEAVITT, M.D., Carson, N. Dak., to Miss Marie Lynch-Bloss of Lebanon, Ohio, at Mandan, N. Dak., September 16.

ALBERT P. FITZSIMMONS, M.D., Tecumseh, Neb., to Miss Nellie Reed of Lincoln, Neb., at Schuyler, Neb., July 12.

ERNEST CARL WEIRICK, M.D., Enola, Pa., to Miss Alice C. Hair of Mechanicsburg, Pa., at Gettysburg, Pa., August 21.

CHARLES EDWARD TOWLE, M.D., Dorchester, Boston, to Miss Agnes Gertrude Kelly of Brighton, Mass., September 17.

JOSEPH I. WOISARD, M.D., Bristol, Conn., to Miss Evelyn Bellrose, of North Grosvenordale, Conn., September 16.

JOHN DALE GRAHAM, M.D., Elephant Butte, N. Mex., to Miss Treane Foster of Columbus, Mo., September 11.

GEORGE CARROLL THOMAS, M.D., U. S. Navy, to Miss Bertha Leeta Pratt of West Chester, Pa., September 15.

MILEY BARTON WESSON, M.D., El Paso, Tex., to Miss Emelyn Grace Guernsey of Delmar, N. Y., August 26.

WALTER LEONARD ALBIN, M.D., University Place, Neb., to Miss Anna Fay Hanson, at Crete, Neb., June 26.

HERBERT ROSS CLARK, M.D., Pierce City, Mo., to Miss Maud Mannering of Springfield, Mo., September 13.

CHARLES CRAWFORD ALLEN, M.D., Ada, Minn., to Miss Mary S. Moore of Arlington, Va., September 5.

ALBERT W. NASH, M.D., Dallas, Tex., to Miss Rose Nielson of Fort Worth, Texas, September 16.

SPURGEON SPARKS, M.D., Cumberland, Md., to Miss Lula V. Gibson in Lexington, Va., in August.

EDWARD LYMAN CORNELL, M.D., to Miss Mabelle Jane Cass, both of Chicago, September 16.

JOHN W. HURT, M.D., to Miss Mary Lovelace, both of Atlanta, Ga., September 22.

CARLOS MONTEZUMA, M.D., to Miss Maria Keller, both of Chicago, September 20.

Deaths

Edwin Bayard Harvey, M.D. For many years secretary of the Massachusetts State Board of Registration in Medicine; died at his home in Westboro, September 28, from heart disease, aged 79. He was born in Deerfield, N. H., and after graduating from Wesleyan University, was made professor of natural science in his alma mater. He graduated from Harvard Medical School in 1866, and settled in Westboro, where he became prominent from the start. He was a member of the school board for eighteen years, superintendent of schools for three years, chairman of the board of trustees of the public library, a trustee of the Westboro Savings Bank and of the State Reform School. He was a member of the House of Representatives in 1884-1885 and of the State Senate in 1894-1895. He was a fellow of the American Medical Association and American Academy of Medicine, president of the Massachusetts Medical Society in 1898-1900 and a councilor for more than thirty years. He drew up the bill establishing the State Board of Registration in Medicine, was the principal factor in securing its enactment, and for eighteen years gave his entire time to the work of secretary of the board. He also drafted and carried through the legislature the bill supplying free text-books to the pupils of the public schools of the state. Dr. Harvey was a born politician of the best sort. He was honest, earnest, fearless, practical and loyal to the best interests of the community as well as those of the medical profession. He was a brainy, forceful man who did things, and did them well, and gave far more thought to his work for the profession than to his own material prosperity.

Leonard Ballou Almy, M.D. Bellevue Hospital Medical College, 1876, died at his home in Norwich, Conn., September 28, after a prolonged illness, aged 62. He was born in Norwich, Conn., received his preliminary education in Yale University, and after his graduation in medicine settled in his home at Norwich. He was president, member of the executive board, surgeon and gynecologist to the William W. Backus Hospital, Norwich. He was a member for many years of the American Medical Association, the Association of the Military Surgeons of the United States and of the Connecticut Medical Society. He served throughout the Spanish-American War as Major and Chief Surgeon U. S. V. and Chief Surgeon of the Second Division, Second Army Corps. Dr. Almy was one of the best-known surgeons of New England and was greatly beloved by his associates.

Nathan Jacobson, M.D. One of the most prominent surgeons of Western New York; died in the Syracuse Hospital for Women and Children, September 16, from angina pectoris, aged 56. He was born in Syracuse and was graduated from the College of Medicine of Syracuse University in 1877. After a year abroad, he returned to his home city and began the active practice of his profession, giving especial attention to surgery. In 1885 he was appointed instructor in surgery in his alma mater and three years later was made lecturer on clinical surgery and laryngology, resigning this position to become professor of clinical surgery. He was a fellow of the American Medical Association and was at one time president of the Onondaga County Medical Society. He was also for many years chief surgeon to St. Joseph's Hospital. He was known beyond the limits of the state as a surgeon of rare skill and good judgment, a man of medical learning, of high character and devoted to the ideals of his profession.

Reginald Heber Fitz, M.D. Harvard Medical School, 1868; a fellow of the American Medical Association and American Academy of Medicine; a member of the American Association of Physicians; Shattuck professor of pathologic anatomy until 1902, Hersey professor of the theory and practice of physic until 1908, and thereafter emeritus professor in his alma mater; co-author with Dr. H. C. Wood of a standard textbook on practice of medicine; physician to the Massachusetts General Hospital, Boston; died at his home in that city, September 30, aged 70.

William Herbert Denslow Lewis, M.D. University of Michigan, 1878; born in New York, April 2, 1856, was educated in America and abroad and was licensed in Illinois in 1878; for many years a member of the American Medical Association and in 1906 chairman of the Section on Hygiene and Sanitary Science. He served as president of the attending staff at the Cook County Hospital, and was a member of many societies and state boards for the study of various phases of sanitary science; died in Chicago, October 5, 1913, aged 57 years.

John Randal Stivers, M.D. Long-Island College Hospital, Brooklyn, N. Y., 1894; a fellow of the American Medical Association; visiting physician to King's County Hospital; instructor in physical diagnosis in his alma mater from 1902 to 1904; for several years treasurer of the King's County Medical Society; president of, and attending surgeon to, the Samaritan Hospital; died at his home in Brooklyn, September 18, shortly after a second operation for sarcoma of the brain, aged 43.

Hiram M. Martin, M.D. University of Michigan, Ann Arbor, 1879; a member of the Illinois State Medical Society; president and professor of diseases of the eye and ear in the Chicago Ophthalmic College; president and professor of diseases of the eye and ear and clinical ophthalmology and otology in Jenner Medical College, Chicago; died in the Passavant Hospital, Chicago, September 29, aged 54.

Charles Lester Leonard, M.D. University of Pennsylvania, Philadelphia, 1889; a fellow of the American Medical Association, and American Roentgen Ray Society; one of the earliest Roentgen-ray workers of Philadelphia; died in Atlantic City, September 22, from malignant disease, due to prolonged exposure to the Roentgen rays, after a long illness and repeated surgical operations, aged 52.

William M. Paine, M.D. Vanderbilt University, Nashville, Tenn., 1880; for several years a member of the State Board of Health, but more recently a banker of Aberdeen, Miss.; president of the Mississippi State Medical Association, 1897-1898; died at his home in Aberdeen, September 3, nine weeks after a surgical operation.

LeRoy Marvin, M.D. Hahnemann Medical College, Chicago, 1870; for two years president of the staff of Hackley Hospital, Muskegon, Mich.; president of the Michigan State Homeopathic Society in 1909; died at his home in Muskegon, September 22, aged 64.

Phares N. Becker, M.D. Jefferson Medical College, 1888; a member of the Medical Society of the State of Pennsylvania; died at his home in Mastersonville, September 13, from tuberculosis, aged 50.

William Johnston Beattie, M.D. Bellevue Hospital Medical College, 1889; a member of the New Hampshire State Medical Society, and a practitioner of New York and Littleton, who was deeply interested in the serum treatment of tuberculosis; president of the Littleton (N. H.) Hospital; was struck by an automobile at Bretton Wood, N. H., September 26, and instantly killed, aged 48.

Emmett Claude Chapman, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1878; a fellow of the American Medical Association; first mayor of West Burlington, Iowa; later in charge of the Santa Fe Hospital, Raton, N. Mex.; since 1894, superintending physician and surgeon of the Santa Fe Hospital, Fort Madison, Iowa; died in that institution, September 22, aged 65.

Charles E. Campbell, M.D. New York Homeopathic Medical College, New York City, 1864; a Veteran of the Civil War in which he served as a surgeon of volunteers; a resident of New York City; president of the Dexter Sulphite Pulp and Paper Company, died at his summer home in Block Island, September 12, after an operation for peritonitis September 12, aged 72.

William Farmer, M.D. Hospital College of Medicine, Louisville, 1895, of Fairmount, Ky.; aged 54; was instantly killed as a result of an automobile accident near Fern Creek, while returning from Louisville August 23. In attempting to cross a wooden bridge, his motorcar skidded, crashed through the railing, and fell to the bed of the creek nineteen feet below.

Albert Thornton Birdsall, M.D. University of Minnesota, Minneapolis, 1896; a member of the Medical Society of the State of New York; clinical assistant in surgery in the New York Post-Graduate School and Hospital; consulting surgeon to the Brooklyn Tuberculosis Clinic; died at his home in Brooklyn, September 24, from pneumonia, aged 43.

Charles Anderson, M.D. Medical College of Ohio, Cincinnati, 1874; a fellow of the American Medical Association; formerly an officer of the Medical Corps of the Army, and a resident of Montecito, Cal., died in his mountain cottage, in the Santa Barbara National Forest, September 17, as the result of burns received in a forest fire, aged 63.

Charles Juergens, M.D. University of Goettingen, Germany, 1865; for several years professor of languages in Milwaukee and later a practitioner of Chicago; once editor of the *Cincinnati Courier* and *Anzeiger;* for 40 years a practitioner of Springfield, Ohio; died at his home in that city, September 18, from gastric ulcer, aged 72.

Robert Emory Moore, M.D. Johns Hopkins University, Baltimore, 1906; a member of the Medical Society of the State of New York, and New York Society of Anesthetists; assistant surgeon to King's County and Bedford Street hospitals, Brooklyn; died at Saranac Lake, N. Y., September 13, from tuberculosis, aged 33.

Benjamin W. Hollenbeck, (License, Indiana, 1897); a practitioner for forty-two years; a member of the Indiana State Medical Association and once president of the Laporte County Medical Society; local surgeon for the Wabash Railway at Westville; died at his home, about September 18, aged 63.

Frederick Conrad Smith, M.D. Baltimore University, 1898; of Philadelphia; died in his office in the northeastern part of the city, September 20, from the effects of poison, self-administered, and gunshot wounds, self-inflicted, it is believed, with suicidal intent, while temporarily insane, aged 36.

John Green Curtis, M.D. College of Physicians and Surgeons, New York City, 1870; a member of the Medical Society of the State of New York; professor and later professor emeritus of physiology in his alma mater; died at his summer home in Chatham, Mass., September 20, aged 68.

James Seymore North, M.D. Detroit Medical College, 1878; for many years justice of the peace and school trustee of "The Old North Neighborhood" near Lansing, Mich.; died at his home in Lansing, May 4, from nephritic abscess, aged 66.

August Henry Willis, M.D. Tulane University, New Orleans, 1908; of Algiers, La.; while returning from a professional call, September 17, was shot at from ambush and killed at French Settlement, Livingston Parish, aged 30.

William Green McWilliams, M.D. Atlanta (Ga.) Medical College, 1882; died at his home in LaFayette, Ga., July 16, from cerebral hemorrhage, aged 59.

Zachary J. Lantorn, M.D. University of Arkansas, Little Rock, 1885; died at his home in Dalark, September 3, aged 74.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

MEDICAL JOURNAL ADVERTISING

And Methods of Obtaining Paid-Up Subscribers

Time was when the postal authorities were lenient with publishers. The names of individuals who had ever subscribed for publications of a certain class were carried on the books indefinitely, whether they paid their subscriptions or not. This permitted a padding of the circulation figures. Of late years, however, the postoffice department requires publishers to have bona-fide paid-up subscriptions if they wish their publications to be carried at the low second-class rate. Certain medical journals have been hard put to it to get a circulation that would be at all attractive to the advertisers, on whose money they depend for continued existence.

Many and various have been the schemes devised whereby the dwindled circulation might be "boosted." Subscriptions could not be given away because the postal laws forbade it. One ingenious method of obviating this difficulty is worked in this fashion: Dr. John Doe writes an article that appears in a reputable medical journal. A few days after its appearance, Dr. Doe receives a letter from the editor and publisher of a medical journal that is in need of a subscription list. He is told that the editor has read his article with much interest and would appreciate receiving from Dr. Doe a brief abstract of it. He does not expect the doctor to go to the trouble of making this abstract for nothing. He will, therefore, on receipt of the abstract credit Dr. Doe with three years' subscription for himself or for one year for himself and one year for each of any other two doctors he may name. For every doctor that bites on this scheme the publisher increases his circulation by three copies and the federal officials are assured that they are paid-up subscriptions—not paid for in cash, it is true, but in "abstracts."

All of this preliminary to a letter recently received:

> *To the Editor:*—Enclosed find letter which speaks for itself. Now what I should like to know from you is the following: Is the *Charlotte Medical Journal* all it should be? Should a doctor contribute to a journal—thereby adding to its prestige and circulation—that carries questionable matter in the advertising pages? If the above journal is off color, does that act as a bar for good men to contribute?
>
> Very truly yours,
>
> L. J. GENELLA, M.D., New Orleans, La.

The letter which our correspondent encloses is on the stationery of the *Charlotte Medical Journal* and signed by the editor of that journal. Here it is:

> "My Dear Doctor Genella:—I have just looked over an article of yours published in the *New Orleans Medical and Surgical Journal* entitled 'Clinical Studies in Pituitary Irritation, with Report of Case.' I would be very glad indeed to have you send me a manuscript or article for the *Charlotte Medical Journal*. Your style of writing is very attractive.
>
> "If you will send me an article for the journal, I will be glad to publish same and will place your name on my complimentary mailing list. Under separate cover I am sending you a copy of the journal.
>
> "Of course I will expect the article to be typewritten."

Whether or not this is a modification of the "abstract" scheme or an attempt to boost the circulation of the *Charlotte Medical Journal* are questions we shall not attempt to answer. As to the questions propounded by our correspondent, they have been answered many times in these pages. We turn to one of the recent copies of the *Charlotte Medical Journal* and examine its advertising pages. On one of the first we find Anasarcin, a product whose fraudulent character was described at some length in THE JOURNAL, May 4 and 11, 1907. On another page we find Tongaline, which has also come in for a fair share of attention (see THE JOURNAL, Sept. 23, 1906, and May 10, 1913). A little farther over we find a half-page advertisement of Bannerman's Intravenous Solution, a nostrum first exploited as a "consumption cure" and now as a cure-all (see THE JOURNAL, May 31, 1913). Cactina Pillets (see THE JOURNAL, March 12, 1910), Hagee's Cordial of the Extract of Cod-Liver Oil (see THE JOURNAL, Oct. 13, 1906) Burnham's Soluble Iodin (see THE JOURNAL, March 28, 1908), Ecthol (see THE JOURNAL, March 13, 1909), Bromidia (see THE JOURNAL, April 21, 1906), Papine (see THE JOURNAL, April 29, 1911), Phenalgine—two advertisements—(see THE JOURNAL, Jan. 13 and 27, 1906, and Jan. 27, 1912) and Sal Hepatica (see THE JOURNAL, March 26, 1910) are some more products which have attained unenviable notoriety but found a safe haven in the advertising pages of the *Charlotte Medical Journal*. Neither must we fail to refer to the advertisement of Duffy's Malt Whiskey (see THE JOURNAL, Nov. 23, 1912), which looks thoroughly at home.

Does our correspondent—in fact, does any conscientious physician having the interest of scientific medicine at heart—want to do anything that will tend to perpetuate therapeutic fraud? Subscribing for or contributing to medical journals whose income is largely derived from nostrums that are as vicious as many of the "patent medicines" advertised in the daily press hampers the medical profession in its fight for honesty in therapeutics and renders largely abortive its fight against fraudulent "patent medicines." So long as the accredited organs of the medical profession tolerate fraudulent "ethical proprietaries" in their advertising pages, just so long will the protests of physicians against the swindling advertisements of "patent medicines" in the daily press fall largely on deaf ears—and justly so.

AN EDITOR'S VIEW OF THE TRAVELING "DOCTOR"

The childlike credulity of the average person with regard to the superlative qualities of the itinerant quack who loudly proclaims his abilities in flamboyant advertisements, appears strange to the editor of the Canon City (Colo.) *Daily Record*. In the issue of Sept. 6, 1913, concerning traveling doctors in general, he says (no doubt having in mind some specific instances of grievous disappointment, or worse, in some of his too trustful neighbors and friends):

> "It's a strange thing to us why Canon City men or women would trust their eyes or their health in the hands of some unknown traveling doctor of any kind. It's a strange thing to us why any Canon City man would buy a suit of clothes or a bunch of teas or groceries from a strange agent whose word and business methods are wholly unknown to the buyer, and whose goods must be taken on faith in a stranger. But it is infinitely more incomprehensible why a man would trust his eyes, or the eyes of his wife or child, to the care of an unknown man whose ability, skill and professional reputation is wholly unknown. The eye is about the most sensitive and delicate organ about the body, and the one a person can least afford to take any chance with. You might afford to take a chance with a stranger on fixing up your corns or ingrown toe nails, but when it comes to the eye or some delicate question of health you should be pretty well satisfied that the man you go to is all right. And if the man lives in Canon City and you can go back to see him any time, he is pretty apt to give your case a good deal more thoughtful care than the man who is here to-day, gets your money, and is off to-morrow, perhaps never to return again. Think it over."

"THE LESSON OF THE FRIEDMANN 'CURE'"

We have commented frequently during the last year or two on the fact that the newspapers are taking more and more interest in public health matters, and we have had occasion to copy into our Economics or Propaganda departments matter that appeared in newspapers verifying this. An editorial appeared in the Boston *Herald*, Sept. 23, 1913, under the title given above. It is too good not to quote:

> "The report in the current number of THE JOURNAL of the American Medical Association utterly discrediting the Friedmann 'cure,' on the basis of the unanimous results of investigators, may seem to partake of lily-gilding to those who long ago were convinced of the man's charlatanry, and of the utter worthlessness of his serum.

"These results cannot be repeated too often. The success of the Friedmann advertising is, unfortunately, still bearing fruit. Like the fisherman's genii in the Arabian Nights, it has grown to such proportion that it can no longer be bottled up. And there are men bearing the medical degree low enough to take advantage of the well-known hopefulness of the consumptive to engage in this wretched business.

"If the great mass of the people, whose credulity makes possible the success of the 'sure cure,' be it for tuberculosis, or cancer 'without the use of the knife,' or for any one of the thousand-and-one ailments that the human flesh is heir to, will but read aright the lesson of the Friedmann fake, it will indeed have proved a 'cure.' It is this:

"No right-thinking physician ever associates with a private remedy. No honorable member of the profession can have any scientific secret from his colleagues.

"No reputable physician ever guarantees—anything. There is no such thing as a sure cure. Every scientific man knows that the human equation cannot be bound by hard-and-fast rules.

"The man with the secret or a guarantee is apt to be a faker. His aim is usually to relieve the pocketbook of the victim.

"Should the misery left in the Friedmann wake, the deluded hopes, the squandered savings, and even the hastened deaths, result in the awakening of the public intelligence in regard to the whole tribe of self-advertising harpies—if from it will come a greater trustfulness in the verdicts of the medical profession—the lesson may not have been in vain."

ANUSOL SUPPOSITORIES

"In Hemorrhoids and all Inflammatory Rectal Diseases, let your first thought Continue to be Anusol Hemorrhoidal Suppositories; they have Earned your lasting Confidence." Thus speaks an attractive folder recently sent to physicians. With a prodigal use of superlatives, the medical profession is told that these suppositories have for years "maintained their World-Wide Reputation" as the "Most Effective, the Safest . . . the Most Economical and . . . the Most Credit-Bringing of all Topical Rectal Remedies." The short memory of the public is notorious; from the point of view of the proprietary exploiter, the short memory of the medical profession must be equally well known. How, otherwise, would a firm try to make physicians believe that a product had "earned" their "lasting confidence" when the result of an examination by the Association's chemists, published in The Journal,[1] had shown that Anusol Hemorrhoidal Suppositories contained practically no "anusol." Moreover, as the Association's findings were a practical verification of the findings of a foreign chemist who also had failed to find any "anusol" in Anusol Suppositories, it is not quite clear what is meant by the term "world-wide reputation." Incidentally, the observant physician will notice that the list of the ingredients given on the Anusol Suppositories labels of 1913 differ from those of the vintage of four years ago. The label of the old boxes gave the ingredients thus:

> Bismuth, iodo-resorcinsulfon (Anusol), Zinc oxydat. pur., Balsam Peruv., Ol. cacao, Unguent cereum.

On the latest label, however, we find these ingredients given:

> "Bismuth oxyiodid and resorcinsulphonate with Zinc oxid and Balsam Peru. incorporated in suitable base."

What will the formula be four years hence?

THE SANATOGEN "GRAND PRIX"

A number of letters have been received recently expressing surprise that Sanatogen had been granted a "grand prix" at the Exhibition of Medical and Surgical Material held in London at the same time that the Seventeenth International Congress of Medicine was in session. The correspondents have asked what such an "honor" meant. The company which exploits Sanatogen in the United States has not been slow to apprise the American public of the award. It has gone further and has written the advertising managers of magazines—including those that had refused Sanatogen advertisements—directing their attention to the fact that Sanatogen was awarded a "grand prize" and opining that "this unusual distinction" should make plain "the desirability of the presence of Sanatogen in the advertising columns of your esteemed publication."

Those familiar with the methods of awarding prizes, medals and certificates to commercial firms and their products at expositions and exhibitions attach little weight to the "honors" thus conferred. It is a fact that most purchasers of large—and expensive—exhibit space at such exhibitions receive some kind of award which, it is tacitly understood, will be a useful advertising asset. Every one can call to mind many food products of mediocre quality that have flaunted on their labels the gold medals received at various expositions.

Nevertheless, it seemed worth while to find out just what the connection was between the commercial exhibition at which Sanatogen received the grand prize and the Seventeenth International Congress of Medicine. The following facts were developed: The commercial exhibition was entirely distinct and separate from the scientific exhibit of the Congress. It was managed and conducted by a British drug journal which had been giving annual "exhibitions" of its own for some years past, and this took the place of its regular exhibition. Immediately after the awards were made public the advertising pages of this drug journal were filled with full-page advertisements of the various products that received prizes. It may interest our readers to know that while the cottage-cheese-glycerophosphate product Sanatogen received a "grand prize" two other proprietary cottage-cheese-glycerophosphate products received "gold medals" at the same time. In the pharmaceutical department of the exhibit a widely—and fraudulently—advertised "patent medicine" received a silver medal! From the facts given it should not be difficult to appraise at its right value the "honor" conferred on Sanatogen. The fact that the exploiters of this preparation are trying to make capital out of this "award" is significant.

Among the members of the Award Jury whose names were given by this drug journal were three men of prominence in Great Britain, to whom we have written. A reply has been received from one, Dr. Stephen Paget, who says: "I was not on the jury, nor do I know anything about the matter. . . . I had nothing whatever to do with the awarding of prizes."

Correspondence

How to Secure Reliable Drugs

To the Editor:—The recent article by M. I. Wilbert on "Carelessness in Pharmacy as a Reason for a Restricted Materia Medica" (The Journal, July 19, 1913, p. 189), very truly sets forth the complications and drawbacks incidental to the evolution of the modern drug-store. As a general emporium for all sorts of small wares and ready-made medicines, for confectionery, cigars and fancy articles, it may be a social necessity as stated, and undoubtedly is so. With the further elaborations of the soda-fountain, the tables for ice-cream customers and the great amount of profit secured along these lines, it is no wonder that the careful compounding of pure drugs should be the smallest element in the business and consequently become neglected.

Mr. Wilbert in his article suggests reform of the drug-store, but specifies shops devoid of "side lines" and equipped with the necessary analytical apparatus. A few such shops still exist in the large cities, but they are so distinctly in the minority that they can exercise but little influence to benefit the general public. The attractive profits of the "side lines" are so great that they carry almost all druggists with them, and, so far as I can judge, the careful handling of drugs is more and more neglected.

A further difficulty arises from the fact that a drug-store supplying the patients of a number of physicians has to include in its stock the favorite drugs and combinations prescribed by each of them—some of these rarely called for. With our large pharmacopeia and the great variety of products of the manufacturing chemists, to say nothing of the legion of nostrums, the druggist may well feel bewildered.

---

[1] Oct. 2, 1909.

The suggestion of Mr. Wilbert that physicians should "take an active interest in evolving a restricted or preferred materia medica list" is certainly desirable; but when one druggist serves a half dozen or more physicians, it may be rather difficult to get them all to keep step in this movement.

Altogether, it must be confessed, the preoccupation of the druggist with his so-called "side lines" and the demoralization of the trade and the public with nostrums make the reform of his business exceedingly difficult. Doubtless it can be accomplished in certain instances under the personal influence and direct supervision of the physician, but in other cases it is practically impossible.

This condition of things is particularly unfortunate for the physician. He is responsible for the life and welfare of the patient and many times pins his faith on the activity of a single medicine. Should this remedy be unreliable or wrongly compounded, or should successive fillings of the prescription vary in activity, both the physician and the patient may suffer.

The matter of reliable drugs is so extremely important that any physician who is unable to obtain satisfactory service from druggists in his neighborhood is justified in supplying his own drugs.

More than twenty years ago I was in the position which I have just indicated, and in justice to my patients adopted the method of providing and dispensing my own medicines. Although I began this with many misgivings, it has worked exceedingly well. Carefully choosing the sources of my drugs and repeatedly testing their clinical efficacy, I can expect definite results from them. The patient gets the first dose promptly, usually before my visit is ended. Thus many uncertainties are avoided. The practice of dispensing does away with the unauthorized refilling of prescriptions and with the annoying habit which many patients have of lending them to their friends. The time required to keep my stock in order is not so great as I supposed it would be. It proves to be well spent, for it is closely interwoven with the art of medicine, in that it familiarizes me with the appearance, taste and other physical properties of my remedies. The expense in my hands has never exceeded 3 per cent. of my total receipts from practice. The method produces the greatest economy of material and of expense. It is interesting to find, after twenty years' use, that dispensing medicines has not led me to resort to the use of the ready-made nostrums or "shotgun" formulas. Examination of my hand-bag to-day shows that out of sixty-three medicines which I habitually carry, forty-seven contain only a single ingredient. The use of alkaloids and of the tablet form of medication greatly facilitates the carrying of medicines, and many tablets can be dissolved and given in liquid form if desired.

I do not wish to be understood as advocating that all physicians should dispense their medicines. Such a course would be unjust to some druggists. The well-equipped and conscientious druggist who has a high standard of work and lives up to it should be encouraged. On the other hand, I firmly maintain that no physician should jeopardize his patients or his own reputation by relying on a prescription service which he knows to be poor. He should, if necessary, provide and dispense his own medicines.

Oliver H. Howe, M.D., Cohasset, Mass.

Failure of Bacterial Sprays to Destroy Klebs-Loeffler Bacillus

To the Editor:—From time to time numerous investigators have advocated the use of bacterial sprays, usually fluid cultures of the *Staphylococcus aureus* or the lactic acid bacillus, for "freeing" the throat secretions of diphtheria carriers from the Klebs-Loeffler bacillus. This procedure defeats the practical value in employing culture methods for the release of quarantine. Frequently when cultures are submitted for diagnosis, the normal throat organisms will outgrow the Klebs-Loeffler bacilli and give negative results. Although these instances are the exception, the result can be more readily obtained by the introduction of pure bacterial sprays of other organisms. During convalescence, when the diphtheria bacillus is present in comparatively small numbers and usually confined to the deeper follicles of the tonsillar structure, cultures made in the usual manner will fail to reveal any other organism than that in the bacterial spray.

The laboratory of the Buffalo Department of Health has made a very careful investigation and finds that the introduction of bacterial sprays does not destroy the Klebs-Loeffler bacilli in throat secretions. On account of the predominance of the organism introduced in the spray often the cultures do not reveal the growth of the Klebs-Loeffler bacilli, but this bacillus still remains present in the source from which the culture was made and by a cessation of spraying will permit it to reappear in cultures.

For these reasons the use of bacterial sprays for obtaining "diphtheria-free cultures" furnishes false security, and defeats the efficacy of the culture method for determining the time for the release of quarantine. Diphtheria-free cultures can be obtained by the introduction of the bacterial spray, but the diphtheria organisms may still exist and are in no way influenced by the presence of the bacteria in the spray. Persons released from quarantine by such cultural evidences may still remain "carrier sources" in the transmission of diphtheria.

William G. Bissell, M.D., Buffalo, N. Y.
Chief, Bureau of Bacteriology, Department of Health.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

VACCINE TREATMENT OF PNEUMOCOCCIC AFFECTIONS

To the Editor:—Please give the consensus of opinion as to the efficacy of the treatment of lobar pneumonia by means of Pneumococcic Bacterin.

W. B. Linton, M.D., Rochester, Minn.

Answer.—There can hardly be said to be a consensus of opinion on this subject. The vaccine treatment of pneumococcic affections is still on trial. So far there is little evidence of its efficiency. The special article on "Bacterial Vaccine Therapy: Its Indications and Limitations," The Journal, June 28, 1913, p. 2046, says, "There is little evidence that stock or autogenous vaccines are of value in pneumococcic infections." Recent books on practice, as a rule, say nothing about this treatment. R. W. Allen ("Bacterial Disease of Respiration," pp. 115 et seq.) gives statistics from various sources, most of which are favorable, but the numbers of cases are so small that no reliable conclusion can be drawn from them. Schorer ("Vaccine and Serum Therapy," p. 158) says, "Active immunization will probably never be of great value in the majority of cases of lobar pneumonia due to pneumococci, because the crisis comes on about the time the results can be expected from the vaccination."

MEDICAL INSPECTION OF SCHOOLCHILDREN

To the Editor:—Can you refer me to literature relating to the subject of medical inspection of schoolchildren?

C. A. W. Zimmermann, M.D., East St. Louis, Ill.

Answer.—The following is a list of references on the subject:

Steven, E. M.: Medical Supervision in Schools. Being an Account of the Systems at Work in Great Britain, Canada, the United States, Germany and Switzerland. Chicago Medical Book Co., 1910. Price $2.
Gulick, L. H., M.D., and Ayres, L.P., Ph.D.: Medical Inspection of Schools, Russell Sage Foundation Publication, Fourth Edition, 1913. Price $1.50.

ADMINISTERING SALVARSAN A SURGICAL PROCEDURE

To the Editor:—1. Is the administration of salvarsan considered a medical or surgical procedure? 2. If in the clinic the diagnosis f syphilis is made and salvarsan is advised, to which department hould the patient be referred?

J. R. Robinson, Augusta, Ga.

Answer.—1. The administration of salvarsan would prob[illegible]ly be classed as a minor surgical procedure.

2. If in the clinic the diagnosis of syphilis is made and alvarsan is advised, that department should undertake the dministration of the drug which is best fitted to do so proprly. If the case be one of cerebrospinal syphilis, it could ardly be properly referred to the department of dermatology r genito-urinary diseases, which might very properly take are of all primary and secondary manifestations. In instances .n which a doubt arises, the case might best be referred to the surgical department, where the drug could be administered under the proper aseptic and technical precautions.

SCHULTZE'S INDOPHENOL-OXYDASE REACTION

To the Editor:—Please give the principles and technic of Schultze's indophenol-oxydase reaction as mentioned in the abstract of Dunn's paper, The Journal A. M. A., June 14, 1913, p. 1924.

J. B.

Answer.—The reaction is described and explained by Dunn as follows:

The films were fixed by immersion in 1 per cent. osmic acid for five seconds. They were then washed thoroughly in running water for five minutes and brought into a mixture of equal parts of dimethylparaphenylenediamin, 1/5 per cent. aqueous solution, and alpha-naphthol, saturated aqueous solution, for periods varying up to half an hour. The films were then washed for a few minutes in running water and mounted on slides in a mixture of equal parts of commercial water-glass and tap-water. Normal blood-films treated in this way show a deep blue staining of the polymorph leukocytes due to formation of indophenol in their protoplasm; this occurs by virtue of the oxydizing ferment or oxydase present in these cells. For details of the reaction see Schultze, *München. med. Wchnschr.*, 1909, lvi, 167, and Dunn, *Jour. Path. and Bacteriol.*, 1910, xv, 20.

A BOOK ON ENZYMES AND THEIR ACTION

To the Editor:—What works can you recommend as the best on the subject of enzymes and their relation to infectious diseases?

Joseph J. Nacker, M.D., Detroit.

Answer.—We know of no book which discusses definitely the relation of enzymes to infectious diseases. The following book gives a complete discussion of enzymes and their action:

Cohnheim, Otto: Enzymes: Six Lectures Delivered under the Huter Lectureship Foundation at the University and Bellevue Hospital Medical College, New York, John Wiley & Sons, 1912, price $1.50

Wyoming: State House, Cheyenne, October 15. Sec., Dr. J. B. Tyrrell, Laramie.

Georgia Reciprocity Report

Dr. C. T. Nolan, secretary of the Georgia Board of Medical Examiners, reports that seventeen candidates were licensed through reciprocity from January 1 to June 10, 1913. The following colleges were represented:

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
University of California, Los Angeles	(1903)	Virginia
George Washington University, D. C.	(1908)	N. Carolina
Atlanta College of Physicians and Surgeons	(1901)	N. Carolina
College of Physicians and Surgeons, Chicago	(1897)*	Missouri
American Medical Missionary College, Chicago	(1900)	Iowa
Fort Wayne College of Medicine	(1891)	Michigan
Louisville Medical College	(1874)	Mississippi
University of Louisville	(1910)	Tennessee
Baltimore Medical College	(1911)	Maryland
Maryland Medical College	(1910)	Maine
Ohio Medical College	(1891)	Indiana
Memphis Hospital Medical College	(1904) (1911)	Tennessee
Meharry Medical College	(1907)	Louisiana
University of Tennessee (1901) Kentucky; (1911) Tennessee; (1911) North Carolina.		
Medical College of Virginia	(1901)	Virginia

* Official information from the college says this man is not a graduate.

Philippine Islands

Dr. C. E. Norris, secretary of the Philippine Islands Board of Medical Examiners, reports that since Jan. 1, 1913, 27 candidates have been licensed to practice medicine. The following colleges were represented:

College	Year of Graduation
Northwestern University	(1911)
Baltimore Medical College	(1909)
St. Louis University	(1908)
Jefferson Medical College	(1892) (1912)
Philippine Medical School	(1913)
St. Tomas University	(1913, 21)

Virginia June Report

Dr. Herbert Old, secretary of the Virginia State Board of Medical Examiners, reports the written examination held at Richmond, June 24-27, 1913. The number of subjects examined in was 18; total number of questions asked, 101; percentage required to pass, 75. The total number of candidates examined was 96, including 3 osteopaths, of whom 72 passed, including 3 osteopaths, 21 failed, and 3 withdrew. Five candidates were licensed through reciprocity. The following colleges were represented:

Book Notices

Medical Inspection of Schools. By Luther Halsey Gulick, M.D., and Leonard P. Ayres, Ph.D. Fourth Edition. Russell Sage Foundation Publication. Cloth. Price, $1.50. Pp. 224, with illustrations. New York: Survey Associates, Inc., 1913.

Medical Supervision in Schools. Being an Account of the Systems at Work in Great Britain, Canada, the United States, Germany and Switzerland. By Edward Millar Steven, M.B., Ch.M. Cloth. Price, $2. Pp. 268, with 40 illustrations. Chicago: Chicago Medical Book Company, 1910.

The Posture of Schoolchildren. With Its Home Hygiene and New Efficiency Method for School Training. By Jessie H. Bancroft, Assistant Director Physical Training, Public Schools, New York City. Cloth. Price, $1.50 net. Pp. 327, with 135 illustrations. New York: The Macmillan Company, 1913.

School Hygiene. By Fletcher B. Dresslar, Ph.D., Specialist in School Hygiene and School Sanitation, United States Bureau of Education. Cloth. Price, $1.25 net. Pp. 369, with 51 illustrations. The Macmillan Company, 1913.

Helping Schoolchildren. Suggestions for Efficient Cooperation with the Public Schools. By Elsa Denison of the New York Bureau of Municipal Research. Cloth. Price, $1.40 net. Pp. 349, with illustrations. New York: Harper & Brothers, 1912.

The growing interest in school hygiene and its problems is well shown by the marked increase in books on the subject which have appeared in the last few months, of which the five under consideration are typical. The volume by Gulick and Ayres is a revision of the book on "Medical Inspection of Schools," published by the Russell Sage Foundation in 1908. The demand was such that three editions of the first book have been issued. This is revised up to January, 1913. Those familiar with the first edition will not require any further recommendation. To others it may be said that the volume contains practically all the essential information needed for becoming familiar with this subject of growing importance. The illustrations and charts are particularly good. Chapters on history and present status of school inspection, detection of contagious diseases, physical examinations, school nurse, cost and salaries and legal provisions are among the most important.

The student of medical school inspection will be able to compare the methods developed in England with those in this country by reading Steven's book on "Medical Supervision in Schools." While Steven discusses the methods adopted in Canada, the United States, Germany and Switzerland, the bulk of his book is devoted to conditions in England.

The social side of school conservation work is presented in Miss Elsa Denison's book, "Helping Schoolchildren," which is devoted to suggestions for efficient cooperation with the public schools. Without taking up the technical side of school inspection or management, Miss Denison discusses private giving, short cuts to publicity, community problems, the special opportunities for women interested in the improvement of school efficiency, the relation of physicians to the schools, and the possibilities of cooperation on the part of churches, business men and citizens in general. While necessarily general and somewhat discursive in its methods, the book contains many suggestions of value and much interest.

The extent to which the consideration of school hygiene is being carried is shown by Miss Jessie H. Bancroft's book on "The Posture of Schoolchildren." The book is copiously illustrated, although some of the photographs, especially reproductions of celebrated paintings and statues, hardly seem worth the space and expense. To the school physician, the conscientious teacher or the parent the book will be of interest and value, even if positive conclusions on all points are not possible at present.

Fletcher B. Dresslar is the special agent of the United States Bureau of Education on School Hygiene and Sanitation. His book on "School Hygiene" is therefore worthy of special attention on account of the broad sources of information at his disposal. Dresslar has not written for the specialist, but for the teacher. He discusses playgrounds, location and construction of school buildings, lighting of schoolhouses, desks, baths, water-supply, ventilation, heating, physical defects of pupils, medical inspection, and what all will agree is perhaps one of the most important of subjects, although generally neglected by writers on school hygiene, the cleaning of schoolrooms, and the qualifications and duties of the school janitor. The book contains a large amount of carefully collected information on a comparatively new subject, and cannot be overlooked by any careful student of school hygiene. The general arrangement of the book is excellent, although the paper and binding are not what it deserves.

Organic Chemistry. Including Certain Portions of Physical Chemistry for Medical, Pharmaceutical and Biological Students (with Practical Exercises). By Howard D. Haskins, A.B., M.D., Associate Professor of Organic Chemistry and Bio-Chemistry, Medical Department, Western Reserve University. Second Edition. Cloth. Price, $2 net. Pp. 430. New York: John Wiley & Sons, 1913.

There is no denying the fact that there is a promising field for a brief and yet comprehensive work on organic chemistry for medical students. The majority of books on the subject have not kept pace with the advances made along lines of organic, biologic, physical and physiologic chemistry as demanded by the up-to-date medical man. These increased demands have multiplied the difficulties in the way of properly presenting the subject to large classes of medical students, and any effort which in the least tends to lessen these difficulties is welcome. This book is a step in the right direction. The demand for foundation principles of organic analysis is very well satisfied in the four chapters devoted to the subjects of purification and identification of organic compounds, molecular weight determinations, elementary analysis, etc. This demand is still further satisfied by the excellent laboratory exercises to be found throughout the book. While we might prefer to see the various groups of compounds arranged in the order of their increasing complexity as to number of elements, that is, CH compounds first, then CHO, then CHO with halogen, sulphur, etc., the present arrangement will perhaps prove more popular. Throughout, more than usual attention is given to medicinal substances, yet still more space might be devoted to this important feature. Structural formulates are used liberally and their value cannot be denied, yet there is a tendency to place too much stress on them and some, if given at all, should be more complete. For example, the "suggested" structure for hexamethylenamin (p. 192) might well be omitted, as also the structure of trional and tetronal (p. 195). The brief chapter on alkaloids could with advantage be much enlarged. The structural formulas for these alkaloids teach little to the medical student, and the space devoted to them could well be used for a more comprehensive discussion of the physical and chemical properties of alkaloidal substances. Since laboratory exercises are so frequently introduced, one or two on behavior, isolation and identification of alkaloids would not be amiss.

Anatomische Grundlagen wichtiger Krankheiten. Fortbildungsvorträge aus dem Gebiet der pathologischen Anatomie und allgemeinen Pathologie für Aerzte und Medizinalpraktikanten: Von Dr. Leonhard Jores, Professor der pathologischen Anatomie an der Kölner Akademie für praktische Medizin. Paper. Price, 15 marks. Pp. 382 with 250 illustrations. Berlin: Julius Springer, 1913.

The author has collected thirty-four of his lectures to postgraduates on a large variety of subjects, each being discussed from the point of view of pathologic anatomy in its bearing on clinical medicine. Among the diseases discussed are anemia, leukemia, endocarditis, arteriosclerosis, aneurysm, cerebral hemorrhage, pulmonary embolism, septicemia and pyemia, pneumonia, diphtheria, scarlet fever, typhoid, appendicitis, tuberculosis, syphilis, paralysis, brain tumor, carcinoma, liver lesions, gastric and intestinal ulcer, Bright's disease and diabetes. Each topic is elucidated by many beautiful illustrations, both in color and in black and white. The style is a most enjoyable one — that of a well-informed and experienced lecturer and close observer. One or more post-mortem examinations forms the basis of each lecture, and the author endeavors to piece together the clinical history of each case by studying the pathologic findings and the method and cause of their production, and then details the clinical symptoms which existed or should have existed in the case. The opinions of others are quoted frequently, and arguments pro and con are quoted, thus giving the reader practically a complete word-picture of every subject discussed. One cannot do otherwise than commend this book, at the same time expressing the wish that there were many more like it.

Medicolegal

Liability for Malpractice in Leaving Tampon in Nose—Patient Not Bound to Return for Further Treatment—Liability of Proven Specialists

(Williams vs. Wurdemann and another (Wash.), 128 Pac. R. 639)

The Supreme Court of Washington affirms a judgment for malpractice. The court says that the defendants were physicians and surgeons specializing in the treatment of diseases of the eye, ear, nose and throat. The plaintiff suffered from a ringing sensation and partial deafness in his left ear and employed them to treat him for his malady. He consulted with one of the defendants particularly, and the latter in the course of the treatment performed a surgical operation on his nose, removing a bony or cartilaginous growth or "spur" therefrom. The wound made by the operation bled so profusely that it was found necessary, in order to stop it, to remove the plaintiff to a hospital and pack that part of his nose surrounding the wound with absorbent cotton. The physician first undertook to pack the nose with cotton tampons pushed in with instruments, but, finding that he could not stop the hemorrhage in that way, ran a string through the nasal channel into the mouth, and by fastening cotton tampons to the string succeeded in drawing them into the nose tight enough to accomplish his purpose. After the lapse of several hours the string on which the tampons were fastened was removed. The plaintiff was then given a lotion for local application and told to return for further treatment. No time seems to have been fixed for his return, and he did not call until some six days later, when he found that the physician who had treated him had left for a visit to the Eastern states to be gone for an indefinite time, and the plaintiff was waited on by the other defendant, to whom he described his condition and who advised him to go home and remain quiet for a time. The plaintiff, however, did not improve as was expected. On the contrary, his nose soon began to discharge fetid matter, and some days later he consulted another physician, who, on examining the nose, found a cotton tampon on one side and an adhesion on the other. That physician treated the plaintiff by removing the tampon, dividing the adhesion and washing out the nose. Recovery speedily followed.

It was the plaintiff's claim that the tampon found in his nose by the last-mentioned physician was a part of the packing put in originally by the first-mentioned one to stop the bleeding following the surgical operation and was by an oversight on his part not removed at the time of the removal of the tampons attached to the string; that this was not discovered by the other defendant whom he consulted some days after the operation, and was the cause of the disorders following that operation. The plaintiff's evidence, the court thinks, tended reasonably to support this conclusion, and, this being so, the court thinks it was for the jury and not the court to say whether the defendants were guilty of such negligence as constituted malpractice.

It was further argued, however, in this connection, that the plaintiff was obligated to return to the defendants for further treatment when he discovered that he was not getting along as well as he should and that his failure so to do was such negligence on his part as would prohibit a recovery against the defendants, but such is not the rule. It is true, undoubtedly, that if a patient employs a physician to treat him for a malady, and receives careful and skilful treatment at his office, but fails to return to the office for further treatment before he is discharged by the physician, and in consequence suffers an injury, he is not entitled to recover against the physician for such injury, and it is also true that a physician's liability ceases the moment his patient dismisses or discharges him, if his treatment of the case has been proper up to that time. But these principles have no application when the physician's treatment of the case has been improper. When being improperly treated the patient is at liberty to quit at any time, and he may hold the physician liable for the injuries suffered by him because of the improper treatment, notwithstanding it is highly probable that the physician, had the patient continued his treatment, would sooner or later have discovered that his treatment was improper and would so have modified it as to effect a cure.

It was objected to certain instructions given by the court on its own motion that it was assumed therein that the defendants were treating the plaintiff as specialists, whereas this action was brought against them as general practitioners and there was no issue as to the character in which they were sued. While it was true that the plaintiff did not allege in his complaint that the defendants undertook as specialists to treat him for the particular malady with which he was suffering, yet he was permitted to testify without objection to facts tending to show that the defendants held themselves out as specialists in the treatment of the disease with which he was afflicted; and the defendants themselves testified, in answer to questions put to them by their own counsel, that they were practicing as specialists in the treatment of diseases of the eye, ear, nose and throat. Under the practice in this state it is not error for the court to instruct the jury according to the case made by the undisputed evidence, notwithstanding such evidence may go beyond the issues made by the pleadings. There was therefore no error in assuming that the defendants undertook to treat the plaintiffs as specialists.

Liability for Malpractice in Causing Dislocation of Arm by Treatment—Proper Subject for Expert Testimony

(Taylor vs. Kidd (Wash.), 129 Pac. R. 406)

The Supreme Court of Washington affirms a judgment for damages for malpractice on condition that it be reduced from $5,500 to $3,500. The court says that the plaintiff, on March 6, 1909, while working on the roof of a house, fell therefrom to the ground, a distance of about 25 feet, and was severely injured. He employed the defendant, a physician and surgeon, to attend him. The defendant found him suffering with two broken ribs, a severe strain on the left shoulder, and various contusions on his body. He immobilized the shoulder and ribs and accorded the contusions the usual treatment. By the latter part of June the broken ribs had adhered, the contusions had healed and some use had been acquired of the injured shoulder. The shoulder, however, was not thought to be making satisfactory progress. The arm had very little motion, attempts to manipulate it caused pain, and it had also become somewhat atrophied. The defendant diagnosed the trouble with the arm as an adhesion of the fibrous tissue surrounding the glenoid cavity of the scapula, which he endeavored to reduce by massage and manipulation, but without success. In the early part of July he advised the plaintiff that a more rigorous manipulation of his arm than could be had without the use of an anesthetic was necessary in order to break up the adhesions, and appointed a time for the patient to meet him at his office and receive such treatment. The plaintiff attended at the office at the time appointed, and received one such treatment, which gave him some pain and caused considerable swelling in the arm and shoulder. On July 17, when the pain and swelling from the first treatment had somewhat subsided, the plaintiff went to the office a second time and his arm was subjected to a further and more rigorous manipulation by the defendant and his assistant. This last operation left the arm in an inflamed condition and much swelling and pain resulted, causing the patient to take to his bed, where he was confined for about ten days. Between that date and August 15 the defendant visited him almost daily and such times as his arm would admit of it subjected it to movement and manipulation. On the last-named date the defendant discontinued the manipulation, prescribed treatment for reducing the swelling and inflammation, and told the patient to come to his office as soon as the swelling should be reduced, when he would examine his shoulder with a Roentgen ray. The plaintiff, however, did not call again at the defendant's office, but on September 6 consulted with a Dr. Bates, who subjected him to a Roentgen ray examination. The plate disclosed a dislocation of the shoulder joint, the head of the humerus projecting downward and inward. To correct the difficulty Dr. Bates advised a surgical operation on the shoulder, which he afterward performed with the assistance of another physician. On cutting into the shoulder he found the head of the humerus in a friable and porous condition, so much so that it was deemed necessary to cut away the end of the humerus for about 2½ inches. After removing this portion of the humerus, the end remaining was set back into the shoulder cavity and the wound inclosed and dressed. At the time of the trial the wound had entirely healed, the arm, while much shorter than it was originally, had recovered much of its lost motion and usefulness, having, as was stated, perhaps 75 per cent. of its original power and scope of motion. The plaintiff thereafter instituted this action for malpractice. In his complaint he alleged the fact of his injury, the employment of the defendant to treat the same, and the manner of the defendant's treatment thereof, alleging as negligence that the defendant dislocated his arm on July 17, 1909, while attempting to break up the adhesions arising from the disuse of the arm following the original injury. Issue was taken on the complaint and a trial had which resulted in a verdict against the defendant in the sum of $5,500. The court thinks that the size of the verdict would indicate that the jury felt inclined to visit the entire loss suffered by the plaintiff on the defendant, whereas he was responsible only for the injury and suffering caused by his own acts, not those caused by the original injury, with which he had nothing to do.

The defendant contended that there was error in the trial judge's refusal to sustain his several challenges to the sufficiency of the evidence, arguing that the evidence failed to show that he did not treat the injury of the plaintiff with that ordinary diligence and skill which physicians and surgeons, practicing in the same and similar communities, ordinarily exercise in like cases. But the court thinks there was on this question sufficient evidence to make a case for the jury. Aside from the general outline of the evidence heretofore given, there was the positive evidence of a physician who examined the arm shortly prior to July 17, 1909, that there was then no evidence of dislocation, and it will be remembered that this was also the defendant's original diagnosis. There was therefore evidence from which the jury could well have found that the defendant dislocated the plaintiff's arm in his endeavor to remedy its anklyosed condition following the original injury; and the fact of such dislocation, and the further fact that he did not discover the dislocation at the times he subsequently manipulated the arm, was clearly evidence that he did not exercise the diligence and skill required of the ordinary physician and surgeon. For such injury as the plaintiff suffered because of such lack of diligence and skill he was, of course, entitled to recover from the defendant.

The plaintiff was permitted, over the objection of the defendant, to propound to his expert witnesses certain questions containing a summary of the facts the evidence on his part tended to establish concerning the treatment accorded the plaintiff by the defendant, and an inquiry whether the treatment thus accorded was such treatment as an ordinarily skilful physician, practicing in the community in which the defendant practiced, would bring to the care of such an injury. This was assigned as error, because, it was argued, it allowed the witness to determine the very question the jury was impaneled to determine. But the court thinks the question not objectionable on that ground. The question whether the treatment accorded the plaintiff's injury by the defendant came up to the standard of ordinary care and skill was not a question within the knowledge of persons of ordinary learning and experience, and hence a jury selected from such persons could not know from the mere description of the treatment whether or not it was reasonably careful and skilful. It was therefore proper to call on persons, learned in the particular science and familiar with the proper practice in like cases, to state whether in their opinion the treatment met the prescribed standard, and this, even though the question whether or not it did meet the required standard, was the ultimate question for the jury to determine. If it be competent for an expert medical witness to state what treatment a reasonably skilful physician would have adopted in a given case, or to give his opinion whether his examination of a person's condition was superficial or thorough, clearly he may give it as his opinion whether a given treatment was or was not ordinarily careful and skilful.

Society Proceedings

COMING MEETINGS

Am. Academy of Ophthal. and Oto-Laryn., Chattanooga, Oct. 27-29.
American Association of Railway Surgeons, Chicago, Oct. 15-17.
A. Assn. for St. and Prev. of Inf. Mort., Washington, D. C., Nov. 14-17.
Clinical Congress of Surgeons of N. A., Chicago, Nov. 10-15.
Delaware State Medical Society, Dover, Oct. 13-14.
Mississippi Valley Medical Association, New Orleans, Oct. 23-25.
Nevada State Medical Association, Reno, Oct. 14-16.
Southern Medical Association, Lexington, Ky., Nov. 18-20.
Virginia Medical Society, Lynchburg, Oct. 21-24.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

Sixty-Third Annual Session, Sept. 22-26, 1913

The President, Dr. Lewis H. Taylor, Wilkes-Barre, in the Chair

Officers Elected

Officers elected for the ensuing year are: president, Dr. Edward B. Heckel, Pittsburgh; vice-presidents, Dr. Henry D. Jump, Philadelphia; Dr. James Burns Anderson, Waynesboro; Dr. Jefferson H. Wilson, Beaver; Dr. U. B. Murray, Washington; secretary, Dr. Cyrus Lee Stevens, Athens; assistant secretary, Dr. William H. Cameron, Pittsburgh; treasurer, Dr. George W. Wagoner, Johnstown.

Place of next meeting, Pittsburgh, Pa.

Medical Legislation

Dr. Lewis H. Taylor, Wilkes-Barre: "To elevate the standard of medical education, and to secure the enactment and enforcement of just medical laws," is a clause from Article II of our ordinances to which I earnestly call your attention. Among important bills in which the state society is directly interested are the midwifery bill, and the amendments to the medical act of 1911 requiring additional qualifications before entering on the study of medicine and a year's service in a hospital after graduation. After Jan. 1, 1914, the State Bureau of Medical Education and Licensure will admit no applicants from within the state nor without, to its examinations until such applicant has completed a year of service in an approved hospital, nor will any one be admitted to begin to practice in the state through reciprocity who after that date has not fulfilled this requirement. The marriage law now in effect in Pennsylvania, unfortunately, does not make a health certificate from a physician necessary, although it provides that the applicant shall take oath that he or she is not afflicted with transmissible disease.

After November 1 the law pertaining to the employment of women will go into effect. The matter of hospital appropriations should be one of vital importance to every physician of the state. That the final determination of the amount to be given to individual hospitals should be left to the judgment of one man is wrong, even if that man does hold the high office of governor of the greatest state in the Union. Appropriations should be made on the basis of work done and the needs of the community rather than on the basis of political influence on legislators or on the judgment of the governor. Further, the problem of a national board of health is one on which we need the influence of a united medical profession.

Modern Ideals in the Care of the Insane

Dr. William K. Walker, Pittsburgh: Insane people are sick people and their adequate care demands scientific methods at the hands of doctors and nurses. The "physiological conception" of insanity emphasizes the importance of the "treatment of the mind" by scientific methods. The housing and care of the insane in the state and county asylums of Pennsylvania are barbarous. In one institution only one out of seven male patients possesses more than one shirt. Seven per cent. only are sleeping between sheets; as many as three patients are sleeping in one room; patients are crowded in the corridors at night, sleeping on mattresses on the floor so close that they almost touch each other. Therefore the cure of mental maladies is difficult, if not impossible. Brutality of keepers is often excused and unpunished. In view of the conditions and the archaic oversight of the mentally afflicted, insanity is rapidly increasing. The first step in reform must be to remove such institutions beyond political control.

DISCUSSION

Dr. Edward E. Mayer, Pittsburgh: It is too often forgotten that with early and proper treatment many of those who become hopelessly insane will be brought back to sanity. We should work for better facilities for this class of sick. Especially should we work for psychopathic hospitals for the acute and incipient case, for state supervision over all the indigent insane and for better psychologic and psychiatric training of the future physician. In Germany every university has a psychiatric clinic.

Dr. William J. Heckson, Vineland: We know that 75 per cent. of mental diseases are hereditary. We must, therefore, devise some means of stopping the propagation of mental defects.

Relation of Venereal Disease to the Public Health

Dr. Edward Martin, Philadelphia: The crusade against social evil should be an organized and concerted effort. It is interesting to read the sanitary records of the cases of chickenpox, measles, mumps and whooping-cough. When, however, either the plutocrat or the pauper reeks with gonorrhea or syphilis in its most virulently contagious form the health authorities are powerless, since these diseases have practically no official existence. They should be made reportable diseases. When the community wants such action it will be taken. An assurance of being reported and, perchance, of being distrained of liberty, would constitute a potent factor against exposure. On the education of the young in sexual matters much hope has been built. The consequences of venereal disease should be taught as a part of general hygiene in the school curriculum without undue emphasis on the sexual side of the subject. The most potent influences against sexual immorality are those of the home, the school and a busy, wholesome life.

DISCUSSION

Dr. Charles J. Hatfield, Philadelphia: I trust that some measure may be taken whereby the force of this society can be exerted in favor of the registration of these diseases. Further I hope that medical opinion will insist on having hospital facilities for the treatment of the disease.

Dr. Lawrence Litchfield, Pittsburgh: Public opinion must be educated and this obligation rests on the medical profession. The medium of communication is the newspaper.

The Problems of the Unfit

Dr. Edward E. Mayer, Pittsburgh: The biologic and sociologic problems involved in medical care of the mentally defective are not sufficiently appreciated by the rank and file of medical practitioners. Not social workers and psychologists, but physicians, must deal with psychogenetic problems of psychoneurotics. Insistence on thorough psychiatric instruction in medical schools, and on efficient psychopathic wards or clinics, will enable the future physician to give wise counsel concerning the life of the psychopathic unfit and the mating of the impure and help to a greater extent in the reduction of vice. I would not decry the work of the practical psychologist, but the feeble-minded should be studied by the physician first of all. Our interest in the problems of the unfit should secure for Pennsylvania more adequate work in our state asylums, state supervision of all our insane, a better trained and larger medical staff in such institutions. Psychopathic wards in some hospital in every city are immediate necessities. I would ask the appointment of a committee for promotion of efficient laws on insanity, to be given, if possible, funds and power to act for the society. Such a committee need not be in conflict with the committee on public policy and legislation and could cope with some of the evils creeping into the public school inspection, the psychologic clinics, the juvenile courts and the moral commissions.

DISCUSSION

DR. THEODORE DILLER: There must be education, first of all, as Dr. Litchfield says, of ourselves, and then of the public. We are doing something regarding the elimination of the unfit from employment by a railroad company. It is required that employees abstain from alcohol and a plan of scrutiny is being carried out to determine whether they have any mental or physical disease rendering them unfit.

INDIANA STATE MEDICAL ASSOCIATION

Annual Meeting, Held at West Baden, Sept. 25-26, 1913

The President, DR. A. C. KIMBERLIN, Indianapolis, in the Chair

SYMPOSIUM ON CHRONIC BRIGHT'S DISEASE

Symptomatology and Diagnosis

DR. G. W. MCCASKEY, Fort Wayne: Bright's disease should be conceived of not simply as a lesion of the kidneys, but as a widespread pathologic process involving many tissues and organs. It is always of hematogenous origin, due to toxins circulating in the blood, and the kidneys suffer most because it is their function to remove these toxins, the irritant effect of which is, therefore, accentuated on these organs. The cardiovascular apparatus comes next in line, and owing perhaps to greater vulnerability, often suffers even more than the kidneys. The symptoms are the combined results of chronic intoxication with relatively slight kidney involvement, aggravated later by limitation of kidney function which forms a vicious circle, intensifying the toxemia which produces the kidney lesion. In making a diagnosis, the clinical history and physical examination are factors of first importance. The presence of albumin and casts does not prove Bright's disease, nor does their absence exclude it. A routine examination of the urine should be supplemented whenever necessary by functional kidney tests and analysis of the blood. The phenolsulphonephthalein test is the best routine method for determining kidney function in general, but is not parallel with the urea excretion, which, in common with the salt and water output, should be separately determined as a basis for classification of Bright's disease from the standpoint of renal pathology.

Vascular Changes Secondary to Bright's Disease

DR. C. F. NEU, Indianapolis: In regard to the treatment of the high blood-pressure and cardiovascular changes accompanying Bright's disease, the general tendency is to give such remedies as directly tend to bring about a reduction of blood-pressure, such as cardiac depressants and vasodilators. There is the danger, particularly in those cases of arteriosclerosis in association with chronic interstitial nephritis, that with the lowered blood-pressure there not infrequently takes place a fall in the urinary output, sometimes amounting to complete suppression. This is almost sure to follow the lack of blood supply to the kidneys, for the high blood-pressure is the result of nature's endeavor to insure an adequate circulation through the renal vessels. Fisher states that there is no justification in giving nitrites, etc., in chronic interstitial nephritis, unless we can show that while reducing the general blood-pressure we are not at the same time reducing the blood supply to the kidneys to a dangerous point.

Eye Lesions

DR. ALBERT BULSON, JR., Fort Wayne: Bright's disease often shows characteristic eye lesions. In the optic nerve the lesion manifests itself in reddening and partial obliteration of the disk. The retina and its immediate neighborhood are usually opaque and striated. In various localities in the retina, usually more numerous in the macular region, may be seen hemorrhages and white patches due to degeneration and inflammation. In the macular region these white patches are generally arranged in the form of a stellated figure. Anatomically these patches and areas of inflammation consist of cells filled with fat granules, dense masses of varicose nerve fibers, accumulations of fibrinous exudate, amorphous débris and masses of round cells consisting probably for the most part of white blood-cells. In most cases there are distinct signs of arteriosclerosis which may be seen by ophthalmoscopic examination. These signs consist of tortuosity of the smaller blood-vessels, white lines or streaks bordering the arteries, and indentation of the veins wherever the arteries cross. In the very early stages of a Bright's disease the fundus lesions are not prominent, but close inspection will often disclose a milky discoloration in the macular region due to inflammatory or degenerative changes.

Influence of Kidney Lesions in Determining the Selection of Anesthetics and Surgical Risks

DR. MILES F. PORTER, Fort Wayne: I hesitate to use large quantities of urea and quinin to produce local anesthesia in a patient with chronic Bright's disease. The sum-total of the effect on the kidneys of an operation done under general anesthesia in the presence of Bright's disease may be beneficial. This is especially true of operations for the relief of obstruction and infection of the bile tracts and for the relief of light conditions in the urinary tract. In acute surgical conditions that immediately threaten life in patients with chronic Bright's disease, the existence of the latter would have no influence in deciding the question as to operation, but should govern the choice of the anesthetic and be duly considered in concluding as to the extent of the operation.

Given a case of acute perforation of the stomach in a patient with chronic Bright's disease, there would be no hesitation as to the necessity for immediate closure of the perforation, but one would perhaps hesitate to excise the ulcer area and do a gastroenterostomy. Again, there should be no hesitancy in opening an acute appendiceal abscess in a chronic nephritis, but the kidney lesion would probably lead one to contend with simply opening and draining the abscess under local anesthesia.

I would like to urge the importance of inquiring into the kidney function in all cases prior to giving a general anesthetic or performing a surgical operation, and to emphasize the importance of preliminary treatment in all cases showing imperfect kidney function, except in those cases in which the demand for surgery is immediate.

DISCUSSION ON BRIGHT'S DISEASE

DR. FRANK B. WYNN, Indianapolis: The profession has been spoiled in the matter of diagnosticating chronic nephritis. It is usually discovered by accident in an examination for life insurance, or only after the patient has the symptom-complex well developed. The quick and easy route to diagnosis, which the urine seems to afford, has led us to overlook and undervalue the early clinical phenomena of the disease. Undue weight has been given by the practitioner to the urine as affording a sure index both as to the type of kidney lesion and the prognosis. The symptomatology, as described by the essayist, showing toxic effects on the part of the nervous system, the gastro-intestinal apparatus, urinary function and eye, give early warnings, that we are prone to call by other names than nephritis. Much has been said of the importance of recognizing pretuberculous states; may it not be just as incumbent on us to be alert for prenephritic states? We should be more frequently on the lookout for the first symptoms of Bright's disease, or for those clinical findings which we know often lead to the development of the disease, such as high nervous tension with increased blood-pressure. In my own experience I have often found that cases which at first I was prone to consider as neurasthenic proved on prolonged study to be incipient nephritis. If we were more cautious in the early recognition of these cases, our views as to prognosis would not be so bad.

Of the early symptoms which should excite our suspicion and careful investigation, none is commoner than a neurasthenic train of manifestations. The individual complains of tiring easily; has lost his former snap and interest in affairs; suffers from indigestion. Persistent anemia should always be carefully investigated with the thought of a possible beginning Bright's disease. A prominent and tortuous temporal artery is very suggestive. Other less frequent early symptoms are: "dead fingers" or feeling as if benumbed by cold; cryesthesia or great sensitiveness to cold; cramps in the calves of the legs and electric light shocks; vertigo; anorexia; pollakiuria or frequent micturition, followed later by polyuria. One or more of these symptoms should always lead us to make a careful study of the urine and a critical physical examination and clinical study of the case.

Dr. H. H. Martin, Laporte: For some time, I have watched with interest the condition of the kidneys in patients suffering with intestinal stasis. I am firmly convinced that many of our so-called cases of Bright's disease are secondary to intestinal stasis, and that early recognition of this fact will oftentimes enable us to improve our prognosis. The urinary picture of a kidney being overwhelmed by intestinal poisons is very constant; in fact, so constant and so similar that it is quite possible in many cases to make a diagnosis of the primary condition from the urinary findings alone.

Dr. F. C. Heath, Indianapolis: I want to emphasize the prognostic significance of the eye lesions in nephritis. Dr. Bull, of New York, a great many years ago, followed up a large number of cases and found that nearly all these patients died within three years of albuminuric retinitis, many of them inside of a year, and quite a number inside of six months. Recently, I have been able to get complete histories of ten cases, many of whom died within two years after the discovery of the retinitis, some of them within six months. One patient had pronounced albuminuric retinitis, but complained of nothing, except a slight smothering sensation in the chest, and yet his urine was heavily loaded with albumin. The doctor in this case made a serious mistake in using too active medication, namely, irritating diuretics which shortened the man's life. He died within six months after the discovery of albuminuric retinitis.

Dr. Joseph Rilus Eastman, Indianapolis: After some experience in the use of the phenolsulphonephthalein test, I have come to the conclusion that it misleads as often as it leads to a better understanding of the kidney lesion. Nobody knows whether the standards of Geraghty and Rowntree are precise or not; they are entirely arbitrary. The urea test is more precise than any color test. When we deal with urea we are dealing with a normal, organic, metabolic product of the kidney. When we deal with phenolsulphonephthalein or indigocarmin or methylene blue, etc., we are dealing with substances which are entirely foreign to the kidney. The kidney reacts in a certain way to the coloring material; because the kidney eliminates, for instance, the phenolsulphonephthalein with certain rapidity, it is no evidence that the kidney can eliminate the abnormal metabolic products with the same rapidity.

Dr. George D. Kahlo, Virginia: We not only have the urinary findings, which we formerly relied on too much, and from which many errors in judgment as to diagnosis and prognosis inevitably occur, but we have the evidence as shown in the vascular system, in the cardiac changes, in the retinal changes and nervous system. The question is, what causes this change, and what are we going to do for the patient after the condition has been recognized as a beginning nephritis? The most important etiologic factor in nephritis, according to Dr. Martin, is intestinal stasis. How often do we find intestinal conditions, whether they be associated with enteroptosis, or whether they be due to an atonic condition of the intestinal wall? We have in practically all these cases a toxic condition—an auto-intoxication, if you wish to call it, but there is a toxemia. There is a beginning nephritis, and the earlier we recognize the toxemia, the better, then we come to the point of how far the kidney is performing its function. We can tell that the structure of the kidney and of the vascular system is endangered by the presence in the system of toxic substances which can be avoided by a proper mode of diet, and what is of primary importance in this connection is the regulation of the diet. It is not merely the restriction or exclusion of proteins from the dietary, but a question of the amount of food that people should eat and the conditions under which the food is prepared, and whether the patient has a normal functionating gastro-intestinal tract to eliminate waste product. It is the accumulation of this waste in these toxins that is the source of irritation to the vascular system, and in connection with which you will find evidences in the kidney pathology, as shown in the microscopic findings of the urine.

Dr. Leonard F. Schmauss, Alexandria: I am surprised that no mention has been made of decapsulation of the kidney in connection with the treatment of chronic Bright's disease. I operated on a patient ten years ago for parenchymatous nephritis. The patient had been confined to bed for six or eight months with general anasarca, large white kidneys. I operated on her. She began to improve after operation and continued to do so. The albumin and casts disappeared. This woman is alive and well to-day.

Dr. Theodore Potter, Indianapolis: In our discussion of so-called functional tests of the kidney, we seem to have overlooked one of the simplest, one of the most natural methods, and one that is universally valuable, and that is putting the kidney under a little strain by exercise, and not by testing it with various sorts of things. If you have reason to suspect the early stage of this disease, examine the patient. If you examine the first urine which that patient passes in the morning, and the next few hours, very frequently you will find it clear from the ordinary evidences of nephritis, but during the middle and active part of the day, they will show up more or less, or if you have the man walk one or two miles before he passes urine, under that little strain, if you examine the urine, you will find kidney abnormality.

Manner of Growth and Surgical Treatment of Cancer of the Breast

Dr. W. D. Gatch, Indianapolis: Unfortunately most women with cancer of the breast come to the surgeon too late for a permanent cure. What is the best treatment for these advanced cases? Should cases with extensive involvement of the axillary lymph-nodes, or with ulceration of the growth and skin metastases be operated on? I believe that no operation with the knife should be done on such patients, unless there is good hope that the growth can be so nearly completely excised that local recurrence will not take place. Mere excision of the primary tumor with perhaps a partial excision of the axillary lymph-nodes simply excites the growth of the cancer, shortens the patient's life, and makes her condition more miserable. If such excision with the knife is not possible, and a painful ulcerated tumor requires removal, the same can be excised with the cautery or with the knife, and the wound immediately cauterized. This procedure does not accelerate the growth. The wound left after it can be given vigorous Roentgen-ray treatment. By these measures it is frequently possible to limit the local growth so that the patient is kept free of pain till she is relieved by death caused by internal metastases.

Any operation which is not followed by an external recurrence of the growth is successful and well worth while.

With breast cancer, as with every other form of malignant growth, the success of operation depends largely on how early in the course of the disease operation is done.

DISCUSSION

Dr. Paul Martin, Indianapolis: It has been my personal experience and observation that when a woman comes with carcinoma, she has had it for ten or twelve months or longer before she consults a physician, and then as the history shows, the physician has kept her under observation for an equal length of time, so that it may be eighteen or twenty months before she goes to the surgeon or before she is brought to him. This lapse of time is the only period the patient has for relief. These patients come too late for operation to do much, if any permanent, good.

DR. JOSEPH RILUS EASTMAN, Indianapolis: There is only one man prominent in the United States, Dr. John B. Murphy, who still advocates that the pectoral muscles should be left in, but I am sure that Dr. Murphy has arrived at that conclusion in very much the same manner that Lorenz arrived at his position relating to the bloodless treatment of congenital hip dislocation. He had an intractable eczema on his hands; he practiced surgery before the day of gloves, could not sterilize his hands, and therefore had to do the operation in a bloodless way. Dr. Murphy advises cleaning out the axilla, using the pectoral muscle as a pad, so that the contraction scar will not lead to edema of the arm, and he is so accustomed to doing this that he continues to do it in the face of anatomic reasons for the removal of the pectoral muscle. If cancer is diagnosticated early when the diagnosis is difficult, the cure is not far to seek. If we wait until the diagnosis is so easy that any bricklayer can make it, then a cure of the condition will be extremely difficult or impossible.

DR. DENNY, Indianapolis: The removal of the breast widely with the pectoral muscles and fascia, cleaning out the axillary lymph-nodes, offers the only chance of saving the lives of these patients until we know more about the cause of the disease. I cannot see any hope of diagnosticating precancerous conditions in the tissues of the body and operating on them. We certainly cannot make such a diagnosis in the breast. The cancerous nodules become deep-seated and we have no evidence on the surface of injury. We cannot remove all moles and warts, but one thing we can do, and should not be afraid of making a mistake, is to remove a breast occasionally for a benign condition which later may become malignant. Such a risk is preferable to waiting for the possibility of malignancy to occur. These women should be educated to consult physicians earlier.

DR. E. D. CLARK, Indianapolis: The best way to prevent cancer of the breast is to remove tumors of the breast when they are found regardless of the question of whether they are benign or malignant. They are abnormal, and they ought to be taken out. This can be done without much mutilation of the breast if we are sure it is cancer. Practically all operations devised for cancer are failures—at least, in my hands. It is only in those cases that I get early and operate on them, regardless of whether the tumor is benign or malignant, that I have any hope of curing.

DR. MILES F. PORTER, Fort Wayne: We want to forget that cancer is a disease of middle life. It is oftentimes a disease of early life. I have seen several cases of cancer of the breast and many cases of cancer of the uterus in women before 30 years of age.

About the closure of the wound, I think we should be reasonable in all things. If, after a radical operation, you can say to the patient, you can get out of the hospital with a closed wound in a week, you will have an opportunity to do a great many more radical operations than you would have if you cannot make that promise. You will succeed in operating in more cases early than in operating on patients who wait three or four months for a wound to close, thereby inducing by irritation of the skin another potential cancer in the case. No man with experience would hesitate to make a sufficiently wide wound to remove the cancerous disease. On the other hand, we should not forget it is the part of wisdom to close the wound if we can, and in the vast majority of cases we can close it without danger of local return.

DR. DAVID ROSS, Indianapolis: I agree with Dr. Porter that there are many cases that come to us in which the radical operation, so-called, is not needed, and yet in that statement I realize it is also impossible to tell. There is a great deal of argument which can be advanced in favor of the position taken by Dr. Gatch in his paper, namely, with early removal you have a chance to save the patient's life, and thorough radical work should be done. I have in quite a number of cases, in which patients would not submit to the radical operation, removed the breast and subsequently treated it with the cautery. I would not undertake the treatment of any tumor that is operable with the Roentgen ray, but I do believe that after a thorough dissection has been made, not only in the incipient cases, but also in those that are inoperable, so-called, by removing the immediate cancerous tissue and cauterizing as may be necessary, then afterward treating the case with the Roentgen ray, we render our patients not only more comfortable but prolong their lives, and as often happens in the aged, we may prevent the recurrence of some other condition which takes the patient away.

DR. JAMES H. FORD, Indianapolis: Early diagnosis is a sine qua non. Every woman should know and be able to teach her children that their breasts should be examined carefully by a competent man at periodical intervals. Dr. Porter says cancer is not always a disease of middle life. My earliest case was in a girl 28 years of age, who had carcinoma of the breast.

DR. THEODORE POTTER, Indianapolis: A number of years ago Dr. W. W. Keen of Philadelphia called our attention to the frequency with which certain lesions became malignant, such as warts, moles, etc. Bloodgood said practically that every cancer of the skin was preceded by some recognizable lesion there. If that is so, it is a very important thing, and whether such a thing is possible or not, every practitioner should know that there are many instances in which these comparatively trivial lesions of the face, the neck and hands, such as moles and warts, do subsequently develop into malignancy.

6. **Non-Protein Nitrogen Retention and Phenolsulphonephthalein Excretion in Experimental Uranium Nephritis.**—The authors found that in acute uranium nephritis in rabbits the excretion of phenolsulphonephthalein in the urine and the

amount of non-protein nitrogen and urea in the blood vary from the normal during the course of the nephritis and return to normal as the nephritis heals. The degree of variation from the normal agrees on the whole with the amount of destruction demonstrated histologically in the kidney. The phenolsulphonephthalein excretion in the urine drops rapidly to its lowest point and returns rapidly to normal with recovery of the kidney. Non-protein nitrogen and urea accumulate gradually in the blood and return to normal gradually, as the kidney recovers. In general, the authors' tests parallel each other as indicators of renal function, but have this essential difference: the amount of phenolsulphonephthalein excretion shows the renal function at the moment; the amount of non-protein nitrogen and urea in the blood is rather a measure of an accumulating difference between the amounts of waste nitrogen produced in the metabolism and the amounts eliminated by the kidneys. The time element, the duration of the condition, is therefore an important factor in this test.

7. **Vegetative Endocarditis.**—The organism described by Lamb and Paton seems to be fairly well established as the cause of the disease. The blood-culture results were very satisfactory. On two separate occasions, with about ten days intervening, three broth flasks showed a pure growth of the organism. A third culture, the first one taken, was discarded as sterile on the fifth day. This was two days before the second culture showed a growth and one day before the last culture was positive. It is possible that had it been kept, it, too, would have been positive. At necropsy, the same organism was obtained from the blood, liver and cardiac vegetations, several times in pure culture, in the other instances in association with the usual autopsy organism, the colon bacillus. Smears of the vegetations showed the organism very definitely. No other variety of bacteria was seen in these smears. Sections of the vegetations also showed the organism very well and again no other bacteria could be identified. The animal inoculations were not so satisfactory. They were carried out on only a limited scale and gave only negative results. As mentioned above, these experiments could not be repeated owing to the loss of the organism. One of the striking things about the case was the fact that the blood-cultures did not become positive until after the time when they are usually discarded. The authors have been unable to find any reference to an organism similar to the one found in this case and have ventured to give it the name *Spirillum surati*, after the name of the locality in which the disease was presumably contracted. The biology and morphology of the organism is described in detail.

8. **Case of Spirillum Infection.**—This case was, in the beginning, considered as having its origin below the diaphragm as a process which had extended upward. It was also presumed to be due to some ordinary pyogenic organism. The assumption that the original infection was below the diaphragm was probably correct, but repeatedly sterile cultures and the absence of any organisms, save the spirilla, from the smears make the supposition of a pure spirullum infection strong. Unfortunately, the condition of the patient was such that it seemed inadvisable to take a blood-culture.

9. **Urinary Sulphur Partition in Various Diseases.**—The lowest average total sulphur excretion (0.88 gm. per day) was found by the authors in a series of thirteen cases of carcinoma. The same series showed also the lowest average neutral sulphur excretion (0.20 gm. per day). The proportion of the neutral sulphur to the total sulphur in this group is considerably higher than the normal proportion of the total sulphur excreted as neutral sulphur. However, the relation of the neutral sulphur to the total sulphur is still higher in the group of seventeen various diseases (not including diabetes or carcinoma). In this group we find that both the relative and absolute amounts of total sulphur and neutral sulphur to be higher than in cancer and diabetes. Eight out of nine cases of diabetes studied showed an increased excretion of neutral sulphur, both in amount and in relation to the total sulphur excreted. From their experience the authors think it is a precarious undertaking to diagnose a malignant tumor on the basis of the absolute or relative amount of the neutral sulphur excreted in the urine, or from the daily excretion of total sulphur.

10. **Reaction of Salomon and Saxl as Diagnostic Test for Carcinoma.**—No differences were found by Greenwald to exist between the urines of patients with carcinoma and other diseases and normal individuals, in the amount of barium sulphate, either absolute or relative to the total sulphur, precipitated by the procedure of Salomon and Saxl. It is therefore concluded that the test is of no value in the diagnosis of carcinoma.

11. **Protein Metabolism of Normal Pregnancy.**—In general, the authors believe that peculiarities in the composition of the urine of normal pregnancy as regards its nitrogenous constituents may be accounted for on purely physiologic grounds.

12. **Renal Complications of Hematin Intoxication.**—Brown found that mild grades of hematin intoxication produce degenerative lesions in the kidneys and the urine shows a trace of albumin and casts. Severe grades of hematin intoxication result in extensive dilatation, injury and occlusion of the renal vessels by hyalin thrombi or emboli, all of which are most pronounced in the glomerular vessels. Extensive degeneration and necrosis of tubular epithelium, hemorrhages and even anemic infarcts result from these vascular lesions. In such cases the urine presents the characteristics of an acute nephritis. In rare instances of severe hematin intoxication, hemoglobinuria may occur. During the period of recovery from acute hematin poisoning and in chronic poisoning, the kidneys show both degenerative and proliferative processes. The glomerular tufts shrink and the capsular space and tubules are more widely dilated. The tubular epithelium shows degeneration and active regeneration with abundant mitotic figures. There are foci of round-cell infiltration and of connective tissue increase. There is also a slight diffuse increase in connective tissue. The urine is increased in amount and contains albumin with hyaline and granular casts. The renal complications of hematin intoxication are believed to be due primarily to dilatation, injury and occlusion of renal vessels under the action of hematin.

13. **Pituitary Extract in Obstetrics.**—Harrison determined experimentally that pituitary is of great value in cases of weakness in uterine movements after the soft parts are well dilated. Failure in these cases is rare, probably less than 1 per cent. The later in labor, but before delivery, the more striking the effect. The danger to the child and mother is very slight. As an addition to some mechanical method, e. g., the Champetier de Ribes' bag, it is of great value in bringing on premature labor or abortion. In the former case it may be sufficient in itself, but there is some risk of tetanus of the cervix, or of the uterus, especially when repeated injections are required. For delivery of the placenta its use is accompanied by the danger of tetanus uteri and retention. In post-partum hemorrhage a considerable percentage of failures may be expected.

15. **Diagnosis of Cancer of Stomach.**—The authors summarize their findings as follows:

1. Edestin is a valuable aid in controlling the proteolytic cleavage of stomach contents.
2. The proteolytic cleavage of stomach contents is due in most instances to regurgitated trypsin, although leukocytes and bacteria probably play some rôle.
3. By the use of edestin with peptone it is possible to materially reduce the errors in non-cancerous and normal cases due to trypsin, leukocytes and bacteria.
4. The edestin-peptone method possesses distinct value in the diagnosis of cancer of the stomach and is of considerable service in the differential diagnosis between benign and malignant anacidity.
5. *High peptolysis* with low proteolysis speaks for carcinoma; high peptolysis with high proteolysis *against carcinoma*.
6. The edestin-peptone method, as in other laboratory tests, is of practical value only when taken in conjunction with the usual clinical and laboratory findings.

26. **Variation in Type of Infectious Disease.**—The evidence studied by Chapin points to the existence in North America during the last fifteen years of two quite distinct strains of small-pox, one the long-recognized type of the text-books, the other marked by decided mildness of symptoms. The latter, Chapin believes, is probably a mutation from the former. Both strains tend to breed true, and though it is possible that a few outbreaks of the severe type may have developed from the mild type there is no conclusive evidence that they have been numerous or extensive.

28. **Virus of Rabies, Freed from Cells of Host.**—From their microscopic examinations Poor and Steinhardt conclude that the virus of rabies as it exists in the submaxillary gland, though possibly visible, is probably of no distinctive form. By the use of various staining methods, by frequent examinations of many viruses with both light and dark fields, with high magnification, no distinctive formed elements were seen. In all cases small granules were readily found. Occasionally there were rings with a central point and cilia-like structures, but these were also found in the control extracts of normal submaxillary glands. Occasionally it seemed that there were more granules in the rabid than in the normal extracts, but no conclusions could be drawn. Experiments on the possibility of obtaining a specific agglutination of the virus of rabies as it occurs in the gland extract from an antirabic serum, obtained by the injection of rabid brain, were tried. By this method it was hoped to exclude tissue reactions. In some cases it seemed as if there were greater clumping of granules in the rabid extracts than in the control normal extracts. Further work is now being carried on along this line and with the opsonic technic, with the possibility of a specific phagocytic action locating the virus in the leukocytes.

29. **Rabies and Experiments in Artificial Cultivation.**—Dogs were inoculated by Moon with street rabies by the direct injection of emulsion of rabid brain into a nerve trunk. Various nerves were employed, but most satisfactory results were obtained by introducing a long needle into the orbital cavity below the eyeball and making the injection at the point where the optic nerve emerges through the optic foramen, the operation being made under ether anesthesia. The animal was then observed closely and at the first sign of unusual restlessness or excitability, usually after twelve to eighteen days, it was killed and the brain taken out under the most careful aseptic precautions. Sections about 3 millimeters in thickness were taken through Ammon's horn and adjacent tissue and incubated in sterile dog-serum in tubes with a layer of olive oil above the serum. The olive oil served the double purpose of preventing evaporation and producing partial anaerobic conditions.

Before placing the brain tissue in the tubes a small bit of gray matter was cut from each section and a smear made as a control for future comparison. At intervals of twenty-four hours tubes were opened and specimens made and compared with their respective controls. The chief difficulty lay in determining the stage at which the dog should be killed and the incubation *in vitro* begun. When this stage was chosen opportunely either no Negri bodies would be seen in the freshly stained preparation or the forms would be very minute, ranging from 1 to 3 microns in diameter. Marked increase in both number and size was evident in twenty-four hours in most cases and the development continued until the tissues became so degenerated from incubation that satisfactory staining was difficult. After forty-eight or seventy-two hours the larger bodies attained a diameter of from 6 to 9 microns, while definite increase in numbers was evident, and the smaller forms were present in abundance. The bodies showed the characteristic dark granules and staining properties, but greater irregularity of form was evident than the Negri bodies show under ordinary conditions.

Controls of normal brain tissue incubated under the same conditions showed no forms which would be mistaken for Negri bodies by an experienced observer. Equally satisfactory results were obtained when the sections were incubated in Ringer's solution instead of serum. Moon believes that these results lend additional support to the view that the Negri bodies are forms in the life cycle of a protozoan organism as against the view that they are the results of the reaction of the living nerve cells to the disease. He suggests that the increase in the size and the number of the bodies perhaps might result from a progressive chemical change in the brain substance, but belittles the notion that the bodies are the results of this experiment.

32. **Toxicity of Human Tonsils.**—The authors endeavored to determine first, whether or not there are toxic substances in the tonsils; second, if present, the nature of those substances, and third, the factors influencing the degree of toxicity. The material for study was obtained from a series of thirty-two tonsillectomies. The tonsils were received in sterile gauze. Extracts were then made by grinding them in a mortar with 10 c.c. of salt solution. The extract thus obtained was either centrifuged or filtered through paper and examined bacteriologically as follows: Blood agar plates were made by adding 1 c.c. of goat blood to 7 to 9 c.c. of agar; the plates were allowed to harden, and one drop of extract to be examined was smeared over the surface of two plates by means of a platinum spatula; after incubating, eighteen to twenty-four colonies were examined grossly and microscopically. The extracts were injected into animals. It was noted that of animals injected with toxic extracts the rabbit usually exhibited, besides the symptoms noted, a marked exophthalmos and contracted pupils. Post-mortem examinations were made in nearly all cases. In no instance were evidences of embolism or thrombosis found. The coagulation of the blood was delayed.

The extracts were prepared and injected in some cases immediately on removal of the tonsils. A few of them were prepared after freezing the tonsils for twenty-four hours; most of them were made a few hours after removal. The toxicity was apparently not affected by these varying conditions. The symptoms and changes in the animals resemble very much the conditions found in anaphylactic shock in rabbits, guinea-pigs and dogs. A few tonsils were apparently harmless in the doses of extract used. A search for the underlying factors was made by comparing the toxicity with the bacterial flora, structural changes and the amount of sediment, i. e., parenchyma, obtainable. The bacterial flora was the only factor that seemed to bear any relationship to the toxicity of the extract. In ten cases in which relatively nontoxic extracts were obtained there was only one in which typical punctate hemolytic streptococcus colonies were present. In the remaining twenty-three cases, from which highly toxic extracts were obtained, punctate, hemolytic, streptococcus colonies occurred fifteen times in large numbers. In three additional cases large colonies of hemolytic streptococci were found. In the remaining five a hemolytic staphylococcus was found three times. Hence the toxic extracts were usually obtained when typical hemolytic streptococci were found on the plates in large or predominating numbers.

34. **Anaerobic Organism Associated with Acute Rhinitis.**—The organism described by Tunnicliff has been found during the early stages of acute coryza, while the discharge is mucoid in character. It has been observed in all cases of acute rhinitis studied, twenty-five different persons having been examined during the acute attack, one during each of four attacks and another during each of five, so that altogether Tunnicliff has made observations during thirty-two distinct attacks. Many examinations were made during the course of the infection in nine of these cases. In the case of an accompanying pharyngitis, tonsillitis or bronchitis, the organism is also found, sometimes in large numbers in the sputum and mucus of the throat. It was also seen in a case of acute pharyngitis unaccompanied by rhinitis. It was present in small numbers in the nose in five cases examined when the rhinitis was disappearing. It was not found in twenty normal persons, in one case of suspected syphilis and one case of diphtheria. A few were observed in one normal nose.

The same organism has been seen in one case of chronic pharyngitis, being practically the only organism present, and in three cases of chronic rhinitis. In some of the lower animals it appears to be present since it was found in the noses of several normal guinea-pigs and rabbits examined, but seen only once in normal dogs. It is not present in the purulent discharge common in rabbits. This same organism was observed in the mucoid discharge from the nose of a dog.

Some of the organisms seem to be flexible and move a little, but most of them appear immobile. They vary from 5 to 8 microns in length and from one-third to one-half of a micron in width; the ends are pointed or slightly rounded; generally the bodies are slightly curved, but may be straight, wavy or bent at one end. A ring and an enlargement in the form of a ball are occasionally seen at one extremity. Sometimes an arrangement in rosettes and bunches occurs, the organisms radiating from a central mass. This organism is a strict anaerobe growing at 37 C. slowly—at least at first. Tunnicliff has isolated it in pure culture eight times, four times from the human nose, three times from the throat and once from the nose of a normal rabbit. It has been cultivated several other times but not isolated in pure culture. It was isolated on the surface of goat blood agar in large test-tubes, the agar being slightly alkaline to phenolphthalein. The cultures were made anaerobic by the Wright method of saturating the cotton stopper with a strong solution of pyrogallic acid and a 5 per cent. sodium hydroxid solution, closing the tube with a tightly fitting cork and sealing it with paraffin. A slight rhinitis has been produced several times in human subjects (twice in Tunnicliff, once in a laboratory assistant) by swabbing a nose which was free from this organism with a pure culture. A pharyngitis accompanied the rhinitis twice. Cultures were made twice and the organisms isolated in pure culture both times.

35. **Bacillus Isolated from Chronic Bronchitis.**—In making bacteriologic examinations of the sputum from a case of chronic bronchitis, suspected of being tuberculous, Tunnicliff found an anaerobic bacillus to be the predominating organism. The bacillus in the sputum is about two microns long by one-fourth micron in width. It was found in enormous numbers, generally in clumps. Some bacilli were seen inside of leukocytes. They were found as a rule in grayish masses in the sputum. Although resembling tubercle bacilli a good deal, they were not acid-fast nor did they retain Gram's stain. They stained uniformly and deeply with carbolgentian-violet, faintly with methylene blue, having a beaded appearance, as they did with carbol-fuchsin. With Giemsa they stained blue. The bacillus is a strict anaerobe, growing slowly, especially during the first generations. The first time it was isolated growth did not begin until the fifteenth day after inoculation. It was isolated on goat blood agar, the agar being slightly alkaline to phenolphthalein. The bacillus is not motile and does not possess a capsule. If inoculated in large numbers the bacillus appears to be toxic to guinea-pigs, but not pathogenic. Repeated intraperitoneal injections in a guinea-pig have so far produced no effect.

36. **Cultivation of Virus of Vaccinia.**—Briefly, from their work thus far on the application of Harrison's method to the cultivation of tissue *in vitro* to corneal tissue plus the virus of vaccinia, the authors are able to state that there is a multiplication of the virus of vaccinia, although no specific vaccine bodies are found in the preparations.

38. **Treatment of Tetanus.**—McClintock and Hutchings believe that the following conclusions are warranted by their experiments: Amputation after the appearance of symptoms is of no value. The toxin appearing in the blood-stream is self-limited even in the fatal cases. There is little if any value in the phenol treatment of the disease. If there is any gain, the authors believe it is probably due to the sedative action of the drug and not to any direct action on the disease process, and that this result may be obtained with greater certainty by other drugs. The magnesium sulphate as used in their experiments subcutaneously was of no value. Antitetanic serum alone has a definite, although usually insufficient, curative effect. From the observation of a large number of animals and quite a number of human beings dying of tetanus, the authors thought that the exhaustion due to the muscular contractions is a large factor in producing fatal results. For this reason much of their work has been given to the attempt to hold these convulsions in check. The presence of a large amount of toxin in the blood several days (in sheep it can be demonstrated four days) before the onset of clinical symptoms makes it imperative that a method be devised for easily determining this. With such a method it is quite probable that a large proportion of tetanus cases could be saved. At present the best tnat can be done in the treatment of tetanus is to neutralize the toxin with repeated doses of serum while controlling the muscular spasm with some drug.

40. **Blindness and Tabes.**—Neither the occurrence of optic atrophy nor of blindness, Maloney points out, retards or influences the evolution of the structural changes which accompany the tabetic process in the spinal cord and elsewhere. The absence of spinal implication in primary tabetic optic atrophy is due to the accident of the localization of the morbid process, and not to any inhibitory influence arising from that localization. The law governing the distribution of the tabetic lesions is as follows: If special fragility exist at any site, and the amount of the tabetic poison be limited, then the site of election for the initial process is the fragile part and it will be the main site of the disease; if no special fragility be present, the disease will be diffuse; if special fragility occur and a large amount of tabetic poison be present, then the fragile is the primary site of the process which later will become generalized, spreading from part to part in the order of the least resistance.

The action of a diminution in visual acuity on ataxia Maloney postulates as follows: Improvement in ataxia will result from a lack of vision after an adequate interval has elapsed: (a) When incoordinating lesions remain stationary;

and the mental capacity for training is not destroyed by cerebral disease. (b) Even if the structural tabetic lesions leading to incoordination extend, provided that the effect of this extension be less than the compensating influence of the blindness. No change in the ataxia will follow loss of vision if the advance of the incoordinating lesion just neutralizes the beneficial influence of the blindness. Obviously this stationary phase can be but temporary. Increase of ataxia in spite of the blindness arises: (a) when the incoordinating lesions advance faster than the coordinating tendency of the blindness grows. Here increase in other morbid signs (spread of sensory and visceral affections) will show the progress of the ataxia to be merely one expression of a general advance in the tabetic spinal lesions and will serve to distinguish it from (b) when blindness is accompanied by cerebral deterioration of such extent as precludes training, and prevents improvement. Mott's conclusion that 50 per cent. of early optic atrophies develop general paralysis is interesting as affording a possible explanation of many of the cases of this class. The law of the relation of loss of vision to ataxia, Maloney says, should read: *Ceteris paribus*, of two tabetics, at any stage of the disease, one blind, the other seeing, the blind has the greater tendency to persist coordinate, the lesser tendency to become ataxic. The degree of this compensatory improvement in the power of coordination will, *ceteris paribus*, tend to rise with the duration of the blindness, according to the training capacity of the person.

For two years Maloney has been applying to the cure of ataxia the method of enhancing sensory perception which the blind teach. He says that the blindfolded tabetics can quickly be taught to appreviate their surviving postural and muscular sense impressions to such a degree that hopeless bedridden ataxics quickly learn to walk again. Moreover, the degree of improvement obtained seems greater than that coming from Frenkel's exercises. Maloney promises in a subsequent paper to describe this new mode of treating ataxia.

49. **Colostomy.**—Hanes proposes a plan by which, he says, the simplest method of producing an artificial anus can be made one of the most reliable in regulating the escape of intestinal contents. The essential features of the ordinary Maydl operation are followed out. A glass, metal or hard rubber rod may be employed to support the spur of the intestine. At the appropriate time an opening is made in the intestinal wall which is to serve as an artificial anus. An incision is made directly over the rod and carried up the anterior wall of the intestine within half an inch of the skin at the upper angle of the abdominal wall. If the feces are liable to remain thin the opening should be at first small and later enlarged if necessity arises. Hanes' rule has been, without variation, for the rod to be removed in a few days succeeding the operation. It is in allowing this rod to remain permanently that simple dressings can be applied and the artificial opening surprisingly well controlled. In the first place the rod remains in the same relative position to the abdominal wall and the opening of the bowel. If there is retraction or distention of the abdomen the parts all maintain the same relative position.

The dressings for regulating the artificial opening consist in the application of a thin piece of gauze over the spur and rod, then a strip of gauze is thrown around the upper segment of the intestine, resting on the gauze, and the two ends of the strip are brought under the ends of the rod and tied. This arrangement makes a constriction around the upper and lower segments of the intestine, and on account of its position under the rod there is no way by which it can escape or relax from its position. The constriction remains constant whatever may be the position or condition of the abdominal wall. The amount of constriction can be regulated to meet the requirements of the individual case. A rubber band can be used, if preferred, instead of the gauze strip. There is no cumbersome and complicated apparatus to be removed when the time for evacuation arises. In addition to the light dressing just mentioned it is only necessary to apply a narrow elastic belt. The patient so far as the dressings are concerned is said to be no more uncomfortable than he would be in wearing an ordinary truss. He has done seven colostomy operations since January of this year and has employed the above method of dressings in six of these cases. It has now been more than seven months since the first operation was done. The patient declares that he has almost complete control over his bowel and experiences but little more discomfort than he did when his evacuations occurred in the normal way.

71 *Effects of Ingestion of Various Oils on Leukocytic Picture in Pulmonary Tuberculosis. M. Solis-Cohen and A. Strickler, Philadelphia.
72 Early Diagnosis and Treatment of Mental Diseases. F. X. Dercum, Philadelphia.
73 *Biologic Interpretation and Surgical Aspects in Painful Indigestion. G. W. Crile, Cleveland.
74 *Stomach from Standpoint of General Practitioner, Specialist and Surgeon. C. G. Stockton, Buffalo.

71. **Leukocytic Picture in Pulmonary Tuberculosis.**—Thirteen patients were given various oils by Solis-Cohen and Strickler, three were given cod-liver oil, two olive oil, three cotton-seed oil, three emulsion of petroleum and two an emulsion of beef fat, butter fat, olive oil, lard and peanut oil with proteins and carbohydrates. The one who examined the blood never saw the patients, did not know what they were taking, nor when they began or ended treatment. The blood was stained with eosin and hematoxylin. The two adult patients on olive oil improved. In both there was a slight decrease in the first two classes of Arneth, while the lymphocytes were also diminished, moderately in one and slightly in the other. Of the three adult patients taking cod-liver oil two improved.

In these the first two classes of Arneth were unchanged or very slightly augmented at first and then were markedly decreased, a slight increase following in one. In the unimproved patient there was a moderate decrease in the percentage of these cells. The lymphocytes were moderately diminished and then markedly increased in one; markedly increased, then moderately decreased and later similarly increased in another, and markedly diminished in the third.

Three children who took cotton-seed oil said they felt better while taking it. The first two classes of Arneth at first were moderately increased in one, moderately diminished in another, and very slightly diminished in the third; these were followed in all by a marked or very marked fall, which in the third was again followed by a moderate rise. The lymphocytes were markedly increased in all, although at first the increase was slight in one and preceded by a slight diminution in another. This was followed by a slight increase in one and by a moderate decrease in two, a very slight increase supervening in one of these. Two adults and a child were given petroleum emulsion, with some improvement of the symptoms in two and no change in one—an adult. In both adults the first two classes of Arneth were slightly augmented, while in the child there was a slight fall, followed by a very marked fall. The lymphocytes were slightly diminished in the unaffected adult, in whom the medicine produced nausea, moderately increased in the benefited adult and slightly diminished in the child when the medicine caused vomiting, followed by a very slight rise as the dose was reduced. Two children, who were given an emulsion of beef fat, butter fat, olive oil, lard and peanut oil with proteins and carbohydrates, said they felt better while taking the medicine. In both there was a marked and a very marked diminution in the first two classes of Arneth, preceded by a slight decrease in one and a slight increase in the other. The lymphocytes were moderately diminished in one despite an increase in the dose, and were slightly diminished at first in the other with the first small dose, but became markedly augmented as the dose was increased.

Of the thirteen patients given oils the first two classes of Arneth were diminished in eleven and increased in two; the lymphocytes were augmented in seven and decreased in six. There was a diminution in the percentage of lymphocytes and of polynuclear cells containing one and two nuclei in all the patients taking olive oil. There was an increase in the percentage of lymphocytes in all but one and a decrease in the first two classes of Arneth in all the patients taking cod-liver and cotton-seed oil. Of the three patients taking emulsion of petroleum the lymphocytes were increased in one and diminished in two, while the polynuclear cells with one and two nuclei were increased in two and diminished in one. In both the patients taking an emulsion of beef fat, butter fat, olive oil, lard and peanut oil with proteins and carbohydrates, the first two classes of Arneth were diminished, the percentage of lymphocytes being augmented in one and lessened in the other.

3. **Urinary Antiseptics.**—This report is summarized as follows:

> The acidity of the urine is readily increased to an extent more than double the normal by acid sodium phosphate, and to a considerably less extent by benzoates. With large doses of citrates it is easily rendered alkaline Putrefaction of the urine and the growth of the staphylococcus is aided by alkalinity and delayed by acidity in proportion to the amount thereof. The reverse is the case with bacillus coli, but only to a small extent; its growth in both acid and alkaline urines quite luxuriant. Hexamethylenetetramin is not itself antiseptic, but acts by producing formaldehyd in the urine. This only takes place in acid urine and the drug is inert in alkaline urine. The degree of antiseptic power is proportionate to the acidity, and where this is normal or higher the drug is far the most efficient of all the urinary antiseptics. Sandalwood oil is a bad general antiseptic, but appears to have a specific action on the staphylococcus which may apply to cocci generally. It is of some use in alkaline urine. Benzoic and salicylic acids are very similar in action. Both are fairly efficient antiseptics in the urine, but are of very little use in alkaline urine. Boric acid is an efficient antiseptic. Its action is unaffected by alkalinity, so that it is the most efficient drug in alkaline urine we possess. Uva ursi is quite a good antiseptic. Its action is certainly not due chiefly to the arbutin it contains.

The whole of this work was done with a view to its clinical application, and the drugs were chosen and investigated with a view to obtaining increased knowledge of their therapeutic application.

The following, Jordan believes, are legitimate practical deductions:

> The use of hexamethylenetetramin (together with acid sodium phosphate which should always be given with it) as a prophylactic before any operation or procedure where the urine may become infected, is of the utmost value, since if the urine is clean and highly acid, and sufficient hexamethylenetetramin is given in small doses to keep it continually present, the urine will not support the life of any organism, and becomes indeed a powerfully antiseptic fluid. Hexamethylenetetramin should only be given where the urine is or can be made acid, otherwise it is inert. It should never be given with potassium citrate in *bacillus coli* infections. If it is desired to try the effect of making the urine alkaline in these conditions use boric acod and uva ursi infusion. Where the urine is undergoing ammoniacal fermentation in the bladder, bladder washes or some operative procedure will always be the most important part of the treatment. The best drugs to use are boric acid in large doses, uva ursi, and possibly sandalwood oil. Sandalwood oil is always worth trying in a cystitis due to the staphylococcus alone. When acid sodium phosphate is prescribed it is as well to write chemical formula (NaH_2PO_4) on the prescription and to ascertain that the right phosphate has been dispensed. It is worth while in giving this drug to estimate the acidity of the urine occasionally (after the simple manner described) to make sure that there is an increase; unless the acidity is kept above 4 or 5 hexamethylenetetramin will not act efficiently, and a high acidity is of much more value than a large dose of hexamethylenetetramin.

4. **Idem.**—Walker concludes that the most effective treatment in acute pure bacillus coli infection is, first, to neutralize the poison with alkalis, and when the symptoms have subsided to turn the urine acid and give urinary antiseptics in progressive doses. In subacute and chronic cases of infection the drugs used should be dictated by the reaction of the urine.

If the urine is acid hexamethylenamin should be given alone; if it is alkaline or neutral it should be combined with sodium acid phosphate or ammonium benzoate. In persistent infection the dosage of hexamethylenamin should be raised until symptoms of formaldehyd irritation commence to appear. The Rimini-Burnam test should be used in every patient treated by hexamethylenamin or other formaldehyd-producing drug. Without it the physician is completely in the dark as to whether formaldehyd is being liberated or not.

5. **Pharmacology of Body Temperature.**—Barbour's first group of experiments show that the health-regulating centers are directly susceptible to cold and heat, as well as to specific neuropharmacologic action. Analogous to the high temperatures which can be produced by the "heat puncture" experiment they have demonstrated a stimulation of the temperature centers with cold, caffein, and betatetrahydronaphtylamin. Depression, giving an antipyretic effect, has been obtained with chloral, antipyrin, quinin and epinephrin. The second series of investigations showed that animals deprived of one cerebrum and corpus striatum (often), or of both cerebra corporo striata and optic thalmi (always), run a subnormal temperature for the days which they survive the operation. In such animals, when given average doses of antipyrin, the phenomena of increased heat dissipation do not occur, and those of heat production are exaggerated. The total effect is a paradoxic rise in body temperature.

6. **Use and Abuse of Hypnotics.**—It is emphasized by Willcox that in every case of supposed "insomnia," it will be well first to make quite sure that absence of sleep really exists. Not infrequently a patient imagines that he has had a sleepless night, whereas he may have slept for several hours. When insomnia really exists it must be remembered that this condition is only a symptom, and its cause in every case must be very thoroughly and carefully investigated. The immediate resource to hypnotic drugs is greatly to be deprecated, since frequently harmful results follow this procedure. Not only is there danger of the development of a drug habit, but commonly the patient develops a sad lack of self-reliance, and is apt to think that he cannot exist without these artificial aids to sleep. It must also be remembered that "sleep induced by drugs" is not the same as natural sleep, and has not the same beneficial value. In every case of insomnia, after having carefully determined the etiologic factors, the first therapeutic measures should be directed toward the treatment and removal of the cause. Any pathologic condition present should be treated by those special therapeutic measures most suitable for the particular case. In addition, general measures for promoting sleep should be considered carefully and recommended, such as a modification of the mode of life and habits of the patient as regards work, rest, diet, exercise, smoking, etc. The conditions of the bedroom and bed itself as regards comfort, quiet, proper ventilation, warmth, etc., should be made suitable. The taking of a hot drink before bedtime may be found to suffice. Simple measures of hydrotherapy, such as baths, douches and in severe cases warm or cold packs, may be employed before hypnotic drugs are given. In some cases massage or electrical treatment have been found helpful. Willcox points out that in many cases of insomnia the employment of such measures as those just described fails to remove this distressing symptom, and in such cases in which the sleeplessness is likely of itself to exercise a harmful effect on the patient's health, it will be advisable to employ some suitable hypnotic drug.

9. **Antiseptic Inhalation in Pulmonary Tuberculosis.**—Many years' close observation leaves no doubt in Muthu's mind that by continuous inhalation volatile antiseptics in the form of vapor mixed with air enter the alveoli as well as the bronchial passages, and get slowly absorbed into the circulation in the lungs and reach the tuberculous focus. Ever since 1895 he has been treating pulmonary tuberculosis with antiseptic inhalations; and since 1899 he has used them in combination with sanatorium treatment. He uses two methods in the sanatorium: the lamp method—where formaldehyd is vaporized in a methylated spirit-lamp, containing a hot-water boiler, the inhalation being taken in patients' own rooms with wholly or partially closed doors and windows for half an hour at a time; the continuous method. The mode of procedure is as follows: When a patient first comes to the sanatorium he is sent to bed and kept there if he shows any signs of a rise of temperature. He has the inhaler for two hours the first day, four hours the second, six hours the third, and eight hours the fourth and the following days. In this way he is gradually prepared to use the inhaler a great part of the day as well as the night. Patients keep on the inhaler while they are walking, resting, reading or playing games, etc. In fact, they are encouraged to keep on the mask at every opportunity from the time they wake up in the morning till late at night, and even during the night. And as they improve and show signs of arrest of the disease the hours are gradually reduced to six, four and two hours a day.

The various solutions used are as follows:

A.—Formaldehyd, 2½ per cent.; chloroform, ʒj; menthol, gr.x; ol. pini pumilin., ♏x; spt. vin. rect. ad ℥j.

B.—Formaldehyd, 5 per cent.; guaiacol, ʒj; chloroform, ʒij; menthol, gr.xv; ol. pini pumilin., ♏xv; spt. vin. rect. ad ℥j.

C.—Guaiacol, ʒij; terebene, ʒj; menthol, gr.xv; ol. pini pumilin., ♏xv; chloroform, ʒij; spt. vin. rect. ad ℥j.

D.—Guaiacol, ʒij; iodin, ʒj; terebene, ʒj; ol. pini pumilin., ♏xv; chloroform, ʒij; spt. vin. rect. ad ℥j.

N.B.—About 10 drops to be sprinkled on the inhaler about every half to one hour.

10. **Action of Digitalis on Blood-Pressure in Man.**—In all thirty-seven cases have been observed by Price. Of these, twenty-six were cases exhibiting some cardiovascular affection, including arteriosclerosis, myocardial degeneration and valvular disease (mitral and aortic), the systolic blood-pressure in some of these being subnormal, in others normal, and in others supernormal; eleven were cases in which on examination of the radial artery and heart nothing abnormal was found. In only one case was there a rise in blood-pressure, in several there was a fall, and in the remaining cases there was no observable change. In a considerable percentage of cases considerable fluctuations in the systolic blood-pressure occurred from day to day. In one case the variations amounted to 26 mm. of mercury. All the patients were first of all given a course of rest before any drug was administered. This plan prevented any drug being credited with results which were in reality due to adventitious circumstances. The sphygmomanometer used was Martin's modification of the Riva-Rocci. Only the systolic pressure was taken, for, in their opinion, it is not certain that as yet they have a method of accurately determining the diastolic pressure. The measurements were taken either every day or nearly every day. In regard to dosage, as a rule Price gave a dram, but sometimes 45 minims, of the tincture of digitalis per day. The cases cited in the present paper were 7 cases of mitral disease, 1 case of mitral disease with also a systolic murmur over the sternum, 1 case of cardiosclerosis, 4 cases of double aortic and mitral systolic bruit, and 2 cases of double mitral and double aortic disease. In all excepting 5 cases there was no observable change in the blood-pressure during the administration of the drug. Of these 5 cases, in 3 there was a fall equal to about 20 mm. of mercury toward the end of the period of administration (in 1 of these cases the fall remained after the drug was stopped); in 1 there was probably a fall; and in 1 there was a rise equal to about 20 mm.—namely, in a case of double aortic disease with also a mitral systolic murmur, arterial wall thick and somewhat tortuous, cyanosis, orthopnea, slight jaundice, much edema, and slight albuminuria, and with a blood-pressure varying between 170 and 180 mm. In some cases observations were taken over prolonged periods, even up to five months.

18. **Mind and Motive.**—In this lengthy paper Nicolson discusses insanity and crime, criminal lunacy, medical jurisprudence of insanity, knowledge of right and wrong, preexisting mental enfeeblement; its degree and character, the question of infidelity, alcoholic excess—(1) delirium tremens, (2) drunkenness to oblivion, and (3) simple drunkenness, epilepsy, delusions, malingering, imposture, feigned insanity, etc. He denies emphatically the heredity of crime while making full allowance for the effects of environment and education, and while laying stress on the hereditary transmission of insanity as a mental condition or neurosis. Nicolson asks that no lunatic shall be hanged, and that no mere criminal shall, on the plea of insanity, be allowed to escape the due punishment for his act of murder. The tests applicable and the difficulties which the medical practitioner will have to surmount if he is to influence rightly the course of justice, discharging a responsibility the weight of which none called on to undertake it can fail to realize, are also considered by Nicolson. He says that what may be treated as knowledge of right and wrong by laymen administering the law may have existed side by side with insanity in a man who is a lunatic, medically recognizable as such and who ought not to be hanged. He holds that no medical man is fully equipped for the practice of his profession unless he has had some months' experience—the more the better—as a medical officer in an asylum. To lack of such experience he ascribes the existence of preventable criminal lunacy, finding this flaw in our social defenses to be due in a large number of cases to be the neglect of symptoms which should indicate the desirability of certification and treatment in an asylum.

20. **Rupture of Spleen.**—Looking up the literature on this subject Scheult found it stated that removal of the spleen was practiced for the first time by Zuccarelli (Saccharelli) in 1554; the operation fell at once into disfavor, for there is no record of its repetition until more than three centuries later, when M. Pean, of Paris, successfully extirpated a cystic spleen in 1867. Since that time the operation has been performed for various conditions and has become a well-established surgical procedure. Up to a few years ago, however, the mortality rate was high; in 1887 it seemed to have been as high as 73 per cent.; Cecil in 1894 estimated it at 51.6 per cent. Since that date there have been decided improvements in the results, due largely, Scheult thinks, to the abandonment of the operation for splenic leukemia and other unfavorable conditions which proved almost invariably fatal. In 1906, B. B. Davis was able to place the mortality at 18 per cent. As regards the removal of the spleen for rupture Reigner recorded in 1893 the first successful case. In 1902 Berger had collected from the literature sixty-nine cases of this nature, with twenty-nine deaths—a mortality of 42 per cent. In 1906 Horz had obtained the reports of thirty-five additional cases with a mortality of 29 per cent. Splenectomy consecutive to wounds of the organ has therefore been attended with a fair measure of success; in any case Scheult says, it is, beyond doubt, the most rational and hopeful treatment, especially when it is borne in mind that the mortality in the unoperated cases has been computed to be more than twice that of the cases in which splenectomy has been performed.

22. **Avoidance of Sudden Death from Induction of Artificial Pneumothorax.**—Most cases of sudden death from the induction of a pneumothorax in Lillingston's opinion are due to errors of technic and he claims that with care these accidents should be extremely rare, and they should not prevent the adoption of the treatment in suitable cases. The most serious accidents are pleural reflex, including laryngeal spasm, gas embolism, aspiration pneumonia, and an uncontrollable accidental pneumothorax due to puncture or rupture of the visceral pleura. Forlanini in 1912 had performed 10,000 operations on 134 patients, of whom 2 died from gas embolism, and 12 exhibited serious symptoms which were very alarming in 5 cases but never fatal. Saugman in 1913, with an experience of about 5,000 operations on 186 patients, had seen two fatal cases at the first injection. Vere Pearson, with an experience of sixteen patients, has seen no fatal accident; and Lillingston with an experience of thirty-two patients and several hundred punctures of the chest, has met with no more alarming symptom than slight shock of a few minutes' duration in one case. The following "don'ts" are mentioned:

> 1. Don't inject gas without satisfactory manometric oscillations, or at a pressure exceeding the atmospheric pressure when beginning a first injection. 2. Don't spare anesthetics. 3. Don't create a high intrapleural pressure. A pressure of 40 cm. of water may cause no discomfort during an injection, but it may be more than doubled by a subsequent fit of coughing, and a leak may thus be sprung in the pneumothorax. 4. Don't induce a pneumothorax during menstruation when reflex excitability may be raised. 5. Don't puncture on the first occasion in many different places in a search for free pleura; patients have collapsed after the sixth or seventh puncture who have tolerated the first punctures well. It is better to continue the search for free pleura in a day or two. 6. Don't inject gas rapidly or at a low temperature. Brauer has once seen symptoms of pleural reflex after the use of cold gas. 7. Don't use large needles or needles with rough surfaces; and don't let the rubber tubing drag on the needle during an injection. 8. Don't inject till the patient's posture is easy and comfortable. 9. Don't hesitate to withdraw the needle at the earliest sign of collapse. 10. Don't operate without brandy and a hypodermic syringe full of ether handy.

23. ***Degeneration of Nucleus Lentiformis.***—The association of cirrhosis of the liver, with degeneration of the nucleus lentiformis in this disease, Henrici says, is so constant as to leave no doubt that there is an important relationship between them. Concerning this relationship two hypotheses present themselves: first, that the same substance which produces the liver changes also affects the lenticular nucleus; and, second, that there is elaborated in the diseased liver some toxic body which has a peculiar affinity for the tissues of the corpus striatum. In a case cited by Henrici there was a marked history of alcoholism, and the liver definitely showed an early stage of Laennec's cirrhosis.

27 *Lesions of Organs of Internal Secretion from Toxic Action of Helminths. (Lésions des organes à sécrétion interne dans l'intoxication vermineuse.) S. P. Bedson.

24. **Vaccination against Typhoid.**—Metchnikoff reports that three chimpanzees treated with Besredka's sensitized living virus bore without harm a dose of typhoid virus which speedily induced typhoid fever in the control chimpanzee. The virus injected under the skin seems to be destroyed there; none of it passes into the blood, urine or stools. One of the soldiers injected with this sensitized virus in the army in Africa contracted typhoid afterward and died, and Metchnikoff believes that the dose must have been too small. Chimpanzees require a larger dose than was used in early trials of the virus. Besredka has injected his virus in 800 persons in various institutions, and there has been no typhoid among them although several cases have developed during the two years among the non-vaccinated. There do not seem to be any contra-indications to its use. he says, adding that by subcutaneous or intramuscular injection it is harmless for man even in large doses. The third article reports favorable

results with the virus given in forty-eight cases of pronounced typhoid.

25. **Ticks and Spirochetes.**—The spirochetes invade all the organs of these insects and even their eggs. One egg of the *Argus persicus* contained more than thirty spirochetes.

27. **Lesions from Helminth Toxins.**—Bedson found that of all the glands with an intestinal secretion, the adrenals seem to suffer most from the toxic action of helminths, whether the intoxication is acute or chronic. The thyroid may also show lesions but seldom except in subacute and chronic intoxication from this cause. The other ductless glands show but slight lesions. His research was done on guinea-pigs, injected with extracts of various tape-worms or with juice from a horse ascaris. The character of the lesions seemed absolutely the same whatever the helminth, and the reaction seemed of the same nature as that to microbian toxins or most chemical poisons.

30 *Early Abortion. (De l'avortement précoce.) V. Wallich.
31 *Conservative Operative Treatment of Tuberculous Processes in Ovaries or Tubes. Patel and Olivier.
32 Pseudomyxoma of the Peritoneum of Appendicitic Origin. A. Deletrez.

30. **Early Abortion.**—Wallich emphasizes that too little attention has been paid heretofore to the cases of early abortion, and yet this may be the starting point of infectious processes in the uterus, ovaries, tubes or peritoneum, or from the relics of the placenta a neoplasm may develop—all of which may be prevented by appropriate treatment in time. The energy of the decidual reaction seems to be more intense when the embryo has lost its vitality, the mucosa apparently striving to throw up a barrier against the cellular elements of the chorion. The result may be a hydatidiform mole, and in prophylaxis of this and other trouble from this source we should be on the alert for the symptoms of early abortion, and not temporize too long in treatment of consecutive uterine hemorrhages which may be the only manifestation at first of the uterine neoplasm. Early abortion is most liable to occur at the first onset of the premenstrual congestion. It is this first congestion after conception which prepares for the embedding of the ovum. The slight disturbances following conception, which can generally be retrospectively traced, cease or become attenuated at this time of the premenstrual congestion. The congestion is aggravated by sexual excitement, by auto-intoxication or other causes favoring congestion in the pelvis. For this reason women inclined to abortion should refrain from everything liable to induce this congestion during the six days of the premenstrual period, keeping very quiet in body and mind, the bowels kept open with mild laxatives or enemas, the diet very simple, possibly refraining from meat and alcohol.

Wallich insists on the necessity for impressing on women that every discharge of blood should be carefully inspected during the entire genital period, and all clots and débris of any kind should be saved for examination. If this is done systematically, as a matter of course, inspection of the membranes expelled will show the state of the abortion. Histologic examination will throw still further light on the case. Treatment should begin at once when the chorionic "infection" starts, and this probably occurs as soon as the ovum dies. It should be removed without delay. Wallich gives an illustrated description of a number of cases which illustrate the importance of these views, showing the remarkable proliferation of tissue as the reaction to the presence of the dead ovum. The specimens dated from the thirtieth to the forty-third day after the last menstruation.

31. **Operative Treatment of Tuberculous Processes in Ovaries or Tubes.**—Patel and Olivier have been reexamining recently 121 patients who have been operated on since 1900 for tuberculosis of the ovaries or tubes. They give the details and outcome in thirty-three cases in which the operation was truly conservative, leaving the uterus or one ovary or tube. The operation was by the vaginal route in sixteen cases and twelve of these patients had to be operated on again, and by a laparotomy, before the lesions actually healed. Of the four others one died and the other required several operations; five in one instance, but the woman was finally cured and has been in good health for seven and a half years.

It is foolish, they declare, to save the uterus after the adnexa has been removed; it is not only useless but is liable to develop myomas and cancer. They query whether it is wise to attempt to retain the adnexa when once a tuberculous process has become installed at any point in them. Examination of eighty women as to the effects of castration under these circumstances showed that there had been scarcely any symptoms attributable to the artificial menopause. The tuberculous process had evidently been preparing them for the castration so that the loss of the ovaries did not affect them as under other conditions. A second operation was never required in the abdominal cases. When the adnexa were left, they are generally tender and the women suffer a little but never enough to demand their removal. On the whole, there is seldom need for restricting the operation to conservative measures in case of tuberculosis of the adnexa. The degree of virulence of the infection, the extent of the lesions and the financial condition should all be taken into account. The necessity for earning her livelihood may turn the scale in favor of suppression of a function which is not vitally necessary.

September 10, XXXIII, No. 37, pp. 433-444

33 *Calcium Reaction in Diagnosis. (La calciréaction et sa signification diagnostique.) G. Rodillon.

33. **Calcium Content of the Urine in Diagnosis.**—Rodillon expatiates on the importance of abnormal losses of calcium as preparing the soil for development of tuberculosis. The French have long emphasized the pathologic importance of the "demineralization of pretuberculosis," and Rodillon has worked out a simple method for detecting it. The calcium is eliminated mainly by the intestines and kidneys: on a vegetable diet by the intestines, and on a meat diet by the kidneys. Consequently the patient must be on a meat diet for two or three days before the test. All that is needed for it is (1) a graduated cylindrical glass tube, 10 cm. high and 15 mm. wide, with a flat bottom; (2) a white plate or card with a heavy black line across the center, 2 or 3 mm. wide; (3) the reagent which is a mixture of neutral ammonium oxalate, 3 gm.; acetic acid crystals, 5 gm.; distilled water, 40 gm. The cylindrical tube is filled to the 5 c.c. mark with the reagent and then with an aqueous solution of some calcium salt, corresponding to 0.2 gm. of lime (CaO) to the liter, up to the 10 c.c. mark. The contents are mixed and then the tube is set on the black line on the card and the fluid is taken up and discarded with a dropper until the black line becomes perceptible below, looking down into the tube. The figure of the graduated scale to which the contents of the tube then reach is thus the standard for comparison. It is usually at the 2.4 c.c. mark. The test is then repeated with the urine to be examined: 5 c.c. of urine is added to the 5 c.c. of the reagent in the tube, and the height of the fluid when the black mark becomes perceptible is the "calcimetric index." The base of the equation is the 0.2 gm. of calcium per liter. This is multiplied by the standard index first obtained, divided by the patient's index. For example, x equals 0.2 multiplied by 2.4 and divided by 3.2 c.c. The index thus derived is 0.15; this represents the proportion of calcium in the liter of the urine tested. In health, on a meat diet, the index ranges from 0 to 0.6 gm.; demineralization is certain when there is over 0.9 gm. On a mixed diet, the normal range stops at 0.5 gm., and on a vegetable diet at 0.2 gm.

34. **Endometritis and Irregular Uterine Hemorrhage.**—Hitschmann and Adler here answer the objections that have been made to their statements five years ago in regard to the structure of the uterine mucosa in normal and inflamed conditions. They review fifty articles that have been published on the subject and declare emphatically that irregular bleeding and pains do not belong to the clinical picture of chronic endometritis. The only sign of chronic endometritis is a suppurative discharge, the fluor. This corresponds to the anatomic findings. Acute or chronic interstitial endometritis is characterized by a round-cell discharge easy to distinguish from the physiologic secretions and from desquamating catarrh of the vagina.

The inflammation with chronic endometritis burrows deep into the tissues and patches burrow here and there absolutely inaccessible to the curet, while they are constantly liable to infect the mucosa anew. It is hard to see how curetting is going to cure such a process. The older the process the less the exudation. Curetting is more liable to aggravate it, as it inevitably and naturally fails to remove all the diseased tissue. Caustic applications also act only on the surface and do not reach the deeper diseased tissues. It seems evident that, to date, radical effectual treatment of a suppurative discharge from the uterus is still an unsolved problem. This does not apply of course to the endometritis which follows abortion or delivery; curetting or formaldehyd here prove their usefulness.

35. **Gonococcus Vaccine in Diagnosis and Treatment.**—Hauser calls attention to the general or focal reaction to the vaccine as very important for the differential diagnosis of gynecologic affections. He found the reaction always positive in the recent gonorrhea cases, with gonococci, and constantly negative when gonorrhea could be positively excluded. In the dubious cases the general or focal reaction often proved a great help, although it is not invariably specific in the vaguer cases. A positive focal reaction is the chief criterion. The history of vaccine diagnosis and therapy of gonorrhea is reviewed in detail and the works of others in this line. He applied the vaccine in differentiation in ninety-five cases. Outside of the typical groups the test failed in four cases and the findings were dubious in five, so that only in 9.5 per cent. of the total was the reaction misleading or unsatisfactory. He warns that a negative reaction does not exclude gonorrhea as the reaction may be hindered by mixed infection or the dose may have been too small or the lesion may be too old to react. His experience with vaccine therapy was quite favorable, but he warns that it is far from being absolutely harmless and should be applied only under constant medical control; never to out-patients. The results were excellent in 29.4 per cent. and satisfactory in 52.9 per cent.; thus 82.3 per cent. of his seventeen patients with gonorrheal lesions in ovary or tube were materially benefited.

40. **Tendon Transplantation.**—Rehn gives an illustrated description of several among the ten cases in the last year in which he had implanted a strip of tendon from some neighboring region after a trauma cutting the tendons in the hand; in one case the operation was on the foot. Two of the patients were children of 8 and 11, the others were mostly young adults. The operation on the foot was done for paralytic club-foot from infantile paralysis at six months. The results were most excellent when the extensor tendons were involved in the paralysis; conditions here are particularly adapted for restitution of function. The task is much more difficult when the flexor tendons of the hands are involved. A minor point which it may prove useful to remember is that wearing a ring may help to substitute the defective transverse ligament. The communication issues from the clinic at Jena in charge of Lexer who has been a pioneer in transplantation of both soft parts and bones.

41. **End-Results of Transplantation of Bones and Joints.**—Küttner reports experiments in this line with bones from cadavers and monkeys, with the post-mortem findings. He remarks that it is amazing to see how Nature uses the implanted bone and how she seems to be grateful for the aid thus afforded. The true bone substance dies, but this aseptic necrosis of the engrafted bone seems to be of no importance from the surgical standpoint, as the muscles grow to it and fine function results, the graft thus proving a prothesis more perfect than can be provided in any other way. The implanted bone tissue is gradually absorbed in the course of years but new construction goes hand-in-hand with the absorption, so that Küttner does not hesitate to say that the end-result is the same as if the implant had not died but had been kept living from the start. One of the cases was that of an implanted hip-joint and he describes the histologic findings on sections of the head of the femur and of the bone above the point of implantation at this point. The second case was also that of a chondrosarcoma of the upper third of the femur and the implanted bone and joint were taken from a cadaver three hours after death.

In the first case the graft of the entire upper part of the femur had been taken from a cadaver thirty-five hours after death. The patient died thirteen months later from metastases in the spine. He gives colored plates of the findings on lengthwise section of the femur. The implant shows solid callus at the point of junction, and there is not a trace of absorption anywhere. The gluteal muscles not only grew to the graft but grew to it at the normal points and a perfect joint capsule developed in time. The illustration shows the almost unbelievable normal attachments of the muscles in the region of the greater trochanter, which had had to be nearly all resected when implanted as it pressed too hard on the soft parts. In the second case the joint was taken from a cadaver three hours after death. The bone fractured later at the point of junction in consequence of an operation for recurrence of the chondrosarcoma, but firm consolidation soon followed. Several other operations for repeated recurrence became necessary until finally two years and three months after the implantation, exarticulation at the hip-joint was required. The results here were similar to those of the first case, substitution for the actual bone substance.

He also illustrates the findings in a child with a congenital defect of the fibula which he corrected by implantation of the fibula from a Java monkey. The Roentgen ray pictures twenty months later show the most gratifying results and justify the extensive application of this method of utilizing bones and joints from monkeys. He has performed several operations of the kind. The bone is taken from the monkey under general anesthesia; the animal is then killed at once and examined with minute care. If necropsy shows that the animal is entirely healthy, the bone, still warm, is then transferred to the patient.

Jianu reports a number of interesting cases, among them what he thinks is the first successful reimplanting of the left forearm and hand which had been torn off in a machine accident. The muscles had been severed in the lower third of the forearm as also both the radial and ulnar arteries and both bones were fractured. The hand was connected only by a thin bridge of skin, 3 cm. wide, at the back of the arm, consisting of merely cellular tissue and one subcutaneous vein. Half an hour after the accident the muscles were sutured, the median and ulnar nerves were joined, and the stumps of the radial artery were invaginated. The ulnar artery was too much injured to attempt its restoration. No attempt at anastomosis of the veins was made as the supply was considered sufficient. The hand was preserved, and now, three years afterward, the sensory, motor and vasomotor disturbances seem to be retrogressing. In some other autoimplants of fingers or foot and in some experimental research the outcome was not successful and the replanted part had to be removed. An implanted testicle from another patient was absorbed after a few months and no effect could be detected from its presence. The implantation of the ovaries from a rabbit in a woman suffering from the artificial menopause was followed by the subsidence of all the disturbances due to loss of ovarian functioning after castration. Although the implanted ovaries were absorbed by the end of three months, yet they seemed to supply the needed stimulus for the harmonious working of the ductless glands.

In another group of cases Jianu transplanted the hypogastric artery in a pedunculated graft to restore a segment of the ureter in a woman after hysterectomy for cancer. The segment of the artery was of course deprived of all connection with the arterial circulation but it was left unmolested in respect to its relations with adjacent tissues; the upper end of the ureter was pushed into the upper end of the artery and the lower end of the artery into the lower stump of the ureter. In another case a segment of the facial was implanted to take the place of Steno's duct and it acts ideally. In another, a segment of the epigastric artery was used to restore the vas deferens in a young man whose left testicle had been excised three years before for tuberculosis. This principle of pedunculated grafts was also successfully applied to restore a segment in the femoral vein, utilizing for the purpose a flap taken from the hernial sac. In conclusion he reports transplantation from one animal to another joined together like the Siamese twins.

42. **Connection between Acute Pancreatitis and Disease of the Gall-Bladder.**—Nordmann was able to induce acute pancreatitis in dogs without fail by closing the outlet to the pancreas and inoculating the gall-bladder with bacteria. A gall-stone at the mouth of the common bile duct is liable to cause the secretion to back up into the pancreatic duct, and acute pancreatitis is almost inevitable when infected bile thus reaches the pancreas. The pancreas tissue suffers from the infection which opens the door to secondary autodigestion of the tissue from the pancreatic juice with resulting fat-tissue necrosis. His experience in eight operative cases of acute pancreatitis confirms in every respect the deductions drawn from fourteen dogs on which he operated. His patients were between 33 and 67 years old, and six had had repeated gall-stone colics. His clinical experience further shows that the prognosis is almost invariably bad when the pancreatitis develops suddenly, with signs of very severe shock and collapse. An operation then may prove the last straw, while otherwise there is always the hope that the severest symptoms of peritonitis with acute pancreatitis may become arrested and encapsulated abscesses develop, the opening of which makes much less demands on the patient than a laparotomy. This occurred in two of his cases. In one the acute pancreatitis followed gall-stone colic, and very painful peritonitis, mainly in the epigastrium, accompanied the severe collapse. The symptoms gradually improved and a subphrenic abscess developed on the left side, which healed after it had been evacuated and the woman recovered, although there were evidences of necrosis in the subcutaneous fat.

In a second case the same sequence of events occurred; the diffuse peritonitic symptoms gradually subsided and an abscess developed in the left lumbar region. Nordmann applied various technics in his cases, finally becoming converted to the advantages of a median incision plus possibly an oblique incision toward the right costal arch. He also emphasizes the importance of draining the common bile duct. Large amounts of pancreatic juice were found in the discharge from the drain, confirming the close communication between the ducts. The sooner operative treatment is applied in pancreatitis the better. It should consist in an ample incision, opening the lesser sac of the omentum, decapsulating the pancreas, tamponing the exposed gland and draining the lesser sac. At the same time the gall-bladder should be opened. This should never be omitted, even when there is no suspicion of gall-stones. With a stone in the common bile duct, if the general condition permits, the duct should be opened and drained. Abscesses and foci of softening in the pancreas should be opened with a blunt instrument and drained.

44. **Traumatic Abscess in the Brain.**—Kempf reports a case in which he ascribes the fine outcome to a second operation in which he closed the gap in the skull with a bone plate taken from the boy's tibia. He gives an illustrated description of the technic.

46. **Operative Treatment of Joint Tuberculosis with Fistulas.** Wrzesniowski reviews his experience in forty-six cases of this kind in which he succeeded in curing 75 per cent. of the patients. The cure has been permanent to date in 55 per cent. of the total, although the cases were all severe processes in shoulder, elbow, knee or ankle with numerous fistulas and profuse suppuration. A wide transverse incision over the articulating line and a lengthwise incision permit the joint to be opened like a book. All the diseased tissues can thus be resected, with ample access. Tuberculosis does not like the daylight but flourishes vigorously in the dark, and the operation aims to remove all the conditions favoring this. He uses Mosetig's filling and Beck's paste as needed after the diseased tissues have been removed. The cleft is then packed with gauze and closed up again. The slit fistula openings are also packed with gauze. Twenty-six illustrations accompany the article.

57 *Practical Importance of the Relations between the Lymph-Nodes and Neighboring Body Cavities. M. Westenhöfer.
58 *Important Sources of Error in the Phenolsulphonephthalein Test of Kidney Functioning. M. Roth.
59 Plastic Operations on the Nose. F. Koch.
60 *Production of Radio-Activity from Non-Radio-Active Elements. M. Levy-Dorn.

57. **The Lymph-Nodes in Connection with the Body Cavities.**—Westenhöfer describes three anatomic specimens of anthracosis in which the lymph-nodes outside the chest showed signs of the anthracosis. In one, the lymph-nodes in the supraclavicular fossa on each side and in the right axilla contained the inhaled coal-dust; in the second, it showed in the lymph-

nodes below the diaphragm along the A. celiaca, and in the third specimen in the epigastric lymph-nodes at the cardia of the stomach. These findings are very significant as they show that the present conceptions of the connection between the lymph-nodes and the neighboring cavities of the body need revision. He states that he has found similar specimens in four pathologic museums, and he is convinced that cancer and tuberculosis may spread in the same way as the coal-dust was carried in these cases.

58. **Sources of Error in the Phenolsulphonephthalein Test of Renal Function.**—Roth states that conditions in women with genital disease or during pregnancy interfere with the test. He also says that if the urine is not all drawn, there may be enough residual urine to interfere with the findings. In measuring the urine, the residual urine must be considered. He found that different makes differed widely in the reactions observed. The lumbar muscles are better suited for the injection, he thinks, than the gluteal; with the latter erroneous findings are liable to result from defective absorption and also from a difference in the depth to which the needle is introduced.

60. **Radio-Activity Induced by Non-Radio-Active Elements.**—Levy-Dorn states that the spark between the electrodes of an induction coil—not in a vacuum—has considerable penetrating power. A photographic plate in three layers of black paper was affected by the rays from this spark, and the ordinary fluorescent screens were lighted up. These rays issue from the cathode. The rays rendered the objects receiving them radio-active for a time, up to two hours in his experiments. The photographic power was equivalent to that of 1/7 mg. radium when the spark was 10 cm. long, with a current of 3 milliamperes, a lead cathode, and twenty minutes' exposure.

68 *Non-Traumatic Tetanus. D. Natonek.

61. **Prostatic Enlargement.**—Lissauer reviews 158 articles that have been published on the subject of hypertrophy of the prostate in recent years. The clinical picture with atrophy of the prostate seems to be practically the same as with hypertrophy. Malignant degeneration of the prostate may also induce the same set of symptoms; the frequency of cancer in the prostate is an additional argument in favor of operative treatment when there are symptoms from the prostatic changes. Albarran found malignancy in fourteen of 100 cases of hypertrophy of the prostate; Kümmel nine times in forty-one cases; Burckhardt eight times in 172, and Steiner twelve times in ninety-six cases. Salinger even goes so far as to assert that in every case of enlargement of the prostate in the elderly, the possibility of cancer should always be considered. The mortality of operations on the prostate was 7 per cent. in Freyer's 432 operations of the kind; 15 per cent. in Cahn's forty cases, and 6.6 per cent. in Steiner's experience with uncomplicated cases, while it was 32 per cent. in his infected material.

62. **Scorbutus in Young Children.**—Hart has found only fifty-one articles on this subject in recent years. He summarizes them and reports anatomic research and experiments on monkeys which have confirmed the identity of scorbutus in both infants and adults. The bone changes are identical but he warns that the diagnosis may be difficult when the classic symptoms are absent: bleeding of the gums, pains in movements and swelling of the joint ends of the bones, generally in the leg, while the joints themselves are spared. Differentiation is scarcely possible when this classic triad is not pronounced or scarcely developed. Exophthalmos may be the only symptom for a time of infantile scorbutus; Habs had a case of this kind which he was unable to explain until the eyelids became discolored, like a "black eye." Small linear hemorrhages in the upper lid were evident in Hart's experiments on monkeys.

The sudden appearance of the swelling of bones is often a clue to the diagnosis. Special emphasis is laid on the warning never to incise one of these swellings; they retrogress soon and do not need incising, while the danger of infecting the subperiosteal hematoma is great. The hematoma may be very large; in one of Hart's monkeys the entire skull was capped by a subperiosteal hematoma. Hematuria may be the early and only sign of a hemophilic tendency, and it may occur with or without actual nephritis. Finkelstein has reported a case of fatal hemorrhagic nephritis in two brothers fed exclusively on sterilized milk, and he explained the clinical picture as a manifestation of infantile scorbutus. The sensitiveness of the bones is an early sign of true scorbutus in young children; they draw up the legs on the abdomen at the lightest touch. The prompt subsidence of the fever when raw milk is given confirms anew the importance of dietetic treatment. Anatomic restitution is a very slow process, and cases are known of return of the symptoms of scorbutus. Finkelstein has reported recurrence after thirteen months of apparent recovery.

Prophylaxis is the main point, avoiding artificial and highly sterilized food for young infants from the very first. If they are absolutely necessary, the period of their use should be restricted to the minimum.

63. **Ulcerative Colitis.**—Kretschmer reviews fifty articles and states that some of the authors mention cases of gonorrheal, syphilitic and tuberculous origin or secondary involvement. Cobliner has reported a case in which the affection evidently had developed from the prolonged use of mercuric chlorid taken according to the therapeutic dosage. Ulcerative colitis is peculiarly tenacious, but there may be remissions with intervals of supposed health for weeks or months. The symptoms are about the same as with cancer of the colon, but direct visual inspection shows the numerous scattered small necrotic scabs, red granular mucosa and subepithelial hemorrhages characteristic of ulcerative colitis. With cancer at the sigmoid flexure, the mucosa generally looks pale. Local treatment is almost indispensable; for this hydrogen dioxid, potassium permanganate, silver nitrate or bismuth are commended as also starch enemas to be retained and hot gelatin enemas. In the majority of cases the ulcerative colitis is restricted to the sigmoid colon; this permits effectual direct local treatment with 2 or 5 per cent. silver nitrate solution or 5 or 10 per cent. zinc chlorid, after the parts have been thoroughly cleansed. Dry powders can also be applied or a strip of gauze dipped in 0.25 per cent. silver nitrate solution can be introduced and left to the next defecation, as Albu recommends. With skill and care these local measures do not distress the patient. Operative treatment is the last resort. To determine whether the colon has entirely healed, Boas examines the rinsing water passed from the artificial anus to the natural anus; if it is free from blood, pus and Charcot-Leyden crystals, the ulcerative process may be regarded as definitely cured and the artificial anus may be closed up.

64. **General Anesthesia with Internal Disease.**—Brunn lists 319 titles bearing on the necessity for extra care in general anesthesia, and discusses the views presented in them. He emphasizes anew the fact that ether promotes the secretion of saliva to such an extent that it is difficult to prevent aspiration of saliva and with it of infectious germs. The assumption that the secretion in the air passages is likewise increased in the same measure is not borne out by the facts observed; the morbidly profuse flow of saliva is the danger. This can be prevented by preparing the patient with a preliminary dose of atropin or other secretion-reducing drug, and by placing the head in such a position that mucus and

saliva will not accumulate in the throat ready to be aspirated into the air passages. The danger for the lungs from ether is thus not an inherent chemical property, and it merely requires technical skill to avoid it. The lung parenchyma may be injured by ether as by any general anesthetic, but no more so than with others. The experiences with local anesthetics have brought into prominence the fact that in many cases it is not the anesthetic used or the anesthesia which is responsible for postoperative pneumonia, but the location of the field of operation. If it is at a point where afterward the fear of pain or the mode of dressing interferes with the expansion of the lungs in breathing, this alone may entail postoperative pneumonia. This should be borne in mind in determining the indications for an operation. Especially dangerous in this respect are laparotomies and operations for hernia, cancer of the breast and goiter. Another danger emphasized is that during general anesthesia the bactericidal power of the lungs is materially reduced. The liver and kidneys are particularly susceptible to the toxic action of chloroform, and this should never be used when either is below par. Tardy chloroform fatalities present usually the picture of acute yellow atrophy of the liver, and the use of chloroform with known existing hepatitis is stigmatized by Brunn as actual malpractice.

65. **Connection Between Disease of the Veins and the Female Genital Organs.**—Among the points which Jaschke gleans from this review of 376 listed articles on this subject is the warning that in the operative treatment of gynecologic pyemia it is important to ligate the median iliac vein, as this is practically the sum of the anastomoses between the different systems of veins in the pelvis. The internal iliac vein, however, need not be ligated as this conveys merely the blood from the rectum and muscular floor of the pelvis. Six cases of gonorrheal phlebitis in women are on record. In treatment of phlebitis few realize the importance of keeping up the bed-rest long enough. The results of operative treatment of the thrombophlebitic form of puerperal fever do not seem very encouraging to date. The great difficulty is to know when to operate; any chill may be the last one and the decision may come too late, or the patient may recover without the operation when the odds seemed all against this. Klein has reported a case in which a patient with typical puerperal pyemia of the severest type and manifest thrombosed veins refused all operative measures and began to convalesce the sixteenth day, after fifteen rigors. Recovery is known even after 100 chills.

The outcome depends in large part on the virulence of the bacteria involved. For this reason operative measures seem most promising in the subacute and chronic cases of pyemia and of little use in the acute forms. The statistics give little idea of the value of ligation of veins for puerperal pyemia; Klein had three deaths in four cases; Latzko seventeen in twenty-seven operations; Bumm seven deaths in ten operations, and four other surgeons one out of two cases each.

In regard to the development of thrombi, all seem to agree now that mechanical causes interfering with the normal flow of blood but not restricting it entirely are the main factors involved. As in any stream, sediment drops down when the current grows more sluggish and at points where eddies form. The blood platelets drop out first and then the leukocytes; there is not a trace of fibrin in a recently formed thrombus but it develops as the current is arrested above. The veins most inclined to thrombosis are always the ones with naturally the most sluggish current; they feel first and most severely any let-up of the expulsive force of the heart. Any weakening of the muscular action of the heart is thus extremely important for the development of postoperative thrombosis. With incipient insufficiency of the heart muscle, prolonged general anesthesia is liable to injure the heart further to such an extent that the general circulation is much below par during the first few days afterward. By getting the patients up early Jaschke has succeeded in warding off thrombosis systematically during the last two years except in a single instance (a patient with an old cancer), while he has had venous thrombosis occur in a number of patients who were obliged to stay in bed longer.

Chlorosis and anemia naturally predispose to thrombosis on account of the sluggish circulation. An important but avoidable additional factor in thrombosis is any operative or other injury of the vessel walls; systematic avoidance of clamps and ligatures *en masse* and other measures liable to injure vessels ward off thrombosis. Myoma, carcinoma and large tumors with dilated veins predispose to thrombosis and hence general anesthesia should be avoided in such cases as far as possible, and the patients should leave the bed early. Jaschke advises getting the patient out of bed for a brief time even the day of the operation in case of anemia or cancer. He cites some Vienna statistics which show that since this has been systematically done there has been no thrombosis among 2,524 parturients getting up from the first to the third day, while there were four cases in 2,500 who did not get up till later. In 387 operative cases there were 0.5 per cent. with thrombosis among those got up early and 2 per cent. among 300 left in bed, including three cases of fatal embolism.

66. **Operative Treatment of Abscess in the Lung.**—Friedmann lists 121 articles published since 1900 and seven others which contain practically the total bibliography on operative treatment of suppurative processes in the lungs outside of tuberculosis and bronchiectasia. He draws a number of conclusions from study of this material. See abstract 117 below.

68. **Non-Traumatic Tetanus.**—Natonek reviews 310 articles, alphabetically listed, the last one cited being Willson's article in The Journal, 1902, xxxviii, 1147. Natonek classifies the cases according as the tetanus developed after trauma without visible external injury; after severe chilling, the "rheumatic form of tetanus" (he cites a number of cases in which the chilling just preceded the first symptoms of the tetanus and evidently cooperated in its development either by reducing the resistance to or enhancing the virulence of the germs); tetanus after spontaneous skin lesions, including freezing and burns; tetanus infection by way of the air passages, teeth, tonsils, alimentary canal or ear (three cases are reported in which infection from the ear was evident; the bacilli were cultivated from the ear discharge in one case); tetanus following operations or after subcutaneous injections or following vaccination. Ninety-three pages are devoted to this comprehensive review of what is known to date in regard to non-traumatic tetanus. Among the practical conclusions of the work is the advice to vaccinate always by superficial scarification and never shut out the air, so that if any tetanus germs are in the virus they will not find conditions propitious to their development.

69. **Operation for Cancer of the Lung.**—Rotter reports the case of a man of 51 with primary carcinoma in the right lung which he treated by resection of the entire lower lobe and part of the diaphragm. The first symptoms had been noted about a year before, oppression and pains. The operation lasted for more than two hours but the patient recovered after a second operation two months later at which the large defect left in the chest wall was closed with a pedunculated flap. A severe febrile sore throat with much catarrh in the air passages led to coughing which induced dyspnea and the patient died with symptoms of suffocation just before the end of the third month. The case is illustrated and compared with twenty-two cases on record of resection of part of the lung. In seventeen cases in which the outcome is known eleven patients survived. In this group the operation had been done for tuberculosis in two cases, for bronchiectasia in seven cases and for tumor in two. One of the six fatalities was due to sepsis from the necrotic stump of the hilus, one to emphysema, one to acute pneumothorax and two to vagus reflex action.

In his case the operation had been attempted and three ribs resected before the diagnosis of cancer was certain. The patient was then transferred to another institution where a differential atmospheric pressure apparatus was available; but the operation proper did not follow until nearly six weeks later.

70. **Excessive Nervous Excitability in Rachitis.**—Kassowitz states that in 370 cases of spasm in the glottis 125 of the children were under 6 months old and 260 not yet one year old. In the total 370 cases the fontanel was closed in only four of the infants, although not less than 110 were over a year old; 118 had no teeth although they were over six months old. He thinks that these findings indicate a tendency to rachitis and a connection between rachitis and spasmophilia. Another argument in favor of this is the connection between the evidences of spasmophilia and the season, paralleling in every respect the seasonal recurrence of rachitis in the months of the year in which infants are confined in the house. (He has previously called attention to this coincidence, suggesting that rachitis may be a manifestation of poisoning from vitiated air.) An additional argument is the remarkably favorable action of the specific treatment for rachitis in the nervous disturbances of spasmophilia. The benefit from phosphorus is convincing, he declares.

71. **Typhoid plus Measles.**—The child in question had not only typhoid and measles but pneumonia, and yet the combined syndrome was not serious. Jastrowitz reports three other cases of atypical typhoid; if there had been a complicating infectious disease the typhoid would have escaped recognition entirely. He has been able to find only three cases on record of typhoid plus measles and four of measles plus paratyphoid. In his first case the assumption was that measles was occurring in a typhoid bacilli carrier, but this was disproved by the persistence of the fever after the measles eruption had subsided and by the diarrhea a week after the measles, by the roseola and by the disappearance of the typhoid bacilli from the stools during convalescence. The other members of the family had typhoid bacilli in the stools but none had had any symptoms from the typhoid infection except that the spleen was unduly large in one. He believes that mild typhoid infections in children are an important factor in the spread of the disease, and urges isolation and free hospital treatment even in the mildest cases when strict isolation in the home is not possible.

73. **Varying Resonance in the Lung as a Sign of Tuberculosis.**—Molnar refers to the familiar fact that the percussion sounds in the lungs vary in intensity with shallow and deep respiration. In health, with weak percussion and deep inspiration the percussion grows fainter; with strong percussion and deep inspiration it grows louder. Over a tuberculous process this change in the sound, he says, is reversed: the sound grows louder with faint percussion during deep inspiration when there is an incipient tuberculous process in the apex below. The contrast with the opposite change noted over the sound apex is striking. He theorizes to explain the causes for the changes.

76. **Attempts at Criminal Abortion in the Absence of Pregnancy.**—Zweifel comments on the peculiar gravity of these cases as the women keep repeating their efforts to bring on abortion when no results follow the first attempt.

81. **Medical Cosmetic Procedures.**—Kromayer discusses in turn the treatment of horny processes, vascular anomalies, affections of the sebaceous glands, disfiguring pigmentation or tumors and disease of the hair. He says of the subeczematous condition of the skin, to which too frequent scrubbing of the hands predisposes, that the roughened skin is suffering from lack of both water and fat. While the skin is still wet, it should be rubbed with a salve to prevent the loss of the water; to wait before applying the salve or cold cream until the hand is dry defeats the purpose. He says of corns and callous processes that excision does little good as the connective tissue beneath has become sclerotic and recurrence inevitably follows. Radiotherapy, on the other hand, influences the connective tissue and restores normal conditions in it and the cure is complete and permanent. Radiotherapy is also almost invariably successful in curing disfiguring proliferation of the tissues of the nose, potato nose, rhinophyma. If there is considerable new formation of blood-vessels, compression and exposure to the blue light of the quartz lamp will correct conditions. It is difficult, however, to apply compression effectually to the nose, and he describes his method of obliterating the prominent vessels with the electric needle (*Spitzbrenner*), heated red hot and applied only for the fraction of a second. A combination of different forms of radiotherapy is useful for nevi, but even at the best the results are far from perfect. The skin never acquires a normal aspect and the reports in the literature, he thinks, are drawn too favorably. As a rule the patients are generally better pleased with the outcome than the physician. The patients are satisfied to find that on account of the partial shriveling of the vessels in the nevus it does not become so congested and conspicuous on exposure to cold, etc., as previously.

84. **Partial Operations for Uterine Myoma.**—Freund cuts out the myoma with a wedge of the uterine walls, including the entire fundus and body of the uterus. This retains the adnexa and a functionally capable uterus, while it permits thorough inspection of the interior of the uterus. He states that it is astonishing how soon the uterus regains normal conditions as to size, shape and consistency.

93 *Congenital Presacral Tumors. W. Parin.
94 *Injury of Crucial Ligaments of the Knee. (Ueber die seltliche Abreissung der Menisken.) Blecher.

91. **Traumatic Epilepsy.**—Matthiae devotes 136 pages to the summaries of 326 cases of operative treatment of traumatic epilepsy, compiled from the literature, giving details of the operation and the findings, and followed by comparison and discussion of the final outcome. He adds two more cases to the list from his own experience. In all but sixty cases the epilepsy was of the jacksonian type. The list is arranged alphabetically by the surgeons' names and the total material is tabulated under various headings. One point thus brought out is that some surgeons, in all their cases, were so much

more successful than others, possibly from superior technic. The after-care seems to be supremely important. Some gave opium or bromid afterward and think it helped; this certainly seemed to be the case in some instances. Other patients seemed to do equally well without it. Absolute abstention from all physical or mental effort for a time afterward seems indispensable. Alcohol exerts a particularly noxious influence on persons inclined to epilepsy, and there can be no question that the bad outcome in some of the cases was due to too free use of spirits afterward. This was particularly evident in one of Braun's cases in which after several years free from the jacksonian epilepsy after the operation, the attacks returned when the young man drank much liquor. He continued to drink and finally developed confirmed epilepsy.

The data presented show that the length of the interval between the accident and the outbreak of the epilepsy does not seem to affect the prognosis. The failures in some cases are possibly explained by an inherited taint. The largest percentage of cures was in patients between 20 and 30: 11 per cent. have been cured for over five years; 6.7 per cent. of those under 10; 6.3 per cent. of those between 10 and 20, and 7.5 and 7 per cent. between 30 and 40, and 40 and 50. In the total 326 cases there were 19 deaths (18.1 per cent.), including three patients with genuine epilepsy. The condition was aggravated by the operation in one case of jacksonian epilepsy and two of genuine epilepsy. No effect was apparent in forty-two cases of jacksonian epilepsy and in seventeen of genuine epilepsy. The twenty-four absolute cures for over five years include two with genuine epilepsy between 20 and 30 and one between 40 and 50. The epilepsy was of two years' standing in eleven of these cases and over ten years in four; nineteen years in Schede's case.

The cured cases are tabulated separately and the point is emphasized that in all but one in this group the local findings amply explained the trouble. This was the case also in the two personal cases reported. The patients were men about 40 with epileptic seizures coming on a few weeks or a year after fracture of the skull. Neither has had any return of the seizures during the six or eight years to date. In conclusion Matthiae reiterates anew the warning that a brain once inclined to epilepsy cannot stand alcohol. Any injury of the skull seems to reduce permanently the tolerance for alcohol. Graf found a tendency to headache in thirty-four persons who had had fracture of the base of the skull and in a number the headache came on regularly after taking alcohol, even the smallest amount. Graf's group is particularly instructive as only three in the group had a claim for disability insurance.

92. Operative Treatment of Traumatic Peripheral Paralysis.—Luxembourg reports seven cases with the ultimate outcome, one in a sixteen months infant; two patients were boys of 14 and 18; one was a girl of 8, and the rest were men under 31. The various operations devised to meet different conditions are described in detail. The outcome was surprisingly good in all but one case. In this operative treatment was not applied until seven years after the nerve had been severed in an operation on a tuberculous focus.

93. Presacral Tumors.—Parin describes a case of congenital tumor developing inward from the sacrum, a teratoma, and compares it with fifteen recorded in the first ten years of the century. His patient was a young woman who since the age of 10 had had suppurating fistulas in the sacral region. A teratoma as large as a man's fist was removed at two sittings from between the sacrum and rectum. In addition Parin summarizes six other cases of tumors in the sacrum-coccyx region in which malignant disease developed. This is so rare, however, that he advises waiting before removing a congenital tumor in this region until the patient has grown stronger and more resistant. Only one fatality is known in the last thirty-five years from removal of a presacral tumor later than early infancy.

94. Internal Injury of the Knee.—Blecher describes three cases of injury of the knee after which the patient held his knee flexed and immovable and the space between the articulating surfaces was extremely tender. This characteristic picture keeping up for two weeks and more is encountered when the semilunar cartilage has been torn off along the side and the torn off cartilage then lies like a foreign body between the articulating surfaces. If torn off so completely that it slips up between the condyles, the trouble is intermittent, incarceration occurring only when the cartilage slips down and gets nipped in the joint. If conditions do not right themselves under eight or ten days of ordinary treatment for a sprained knee, then the knee should be opened without delay and the cartilage reduced and held in place with a stitch or two unless it shows signs of severe injury, in which case it should be removed. He aims to retain it whenever possible.

95. Progress in Surgery of Peripheral Nerves.—The Journal has previously mentioned Stoffel's work in this line, 1913, lx, 793. He has confirmed the fact that a nerve is merely a bundle of separate motor and sensory fibers, and that it is possible to trace in a transverse section of the nerve the various fiber-tracts which pass to given muscles. At a touch with a needle electrode to the tract, the muscle contracts. He has been the explorer of the topography of the transverse section of the nerves, and has applied the points thus learned in very successful treatment of spastic paralysis, weakening the innervation of the paralyzed muscles and reinforcing the strength of the antagonists. The groups of muscle involved in the spastic paralysis are released from their bondage by partial resection of the corresponding motor nerve tracts. He had performed 172 operations on peripheral nerves up to June, 1913.

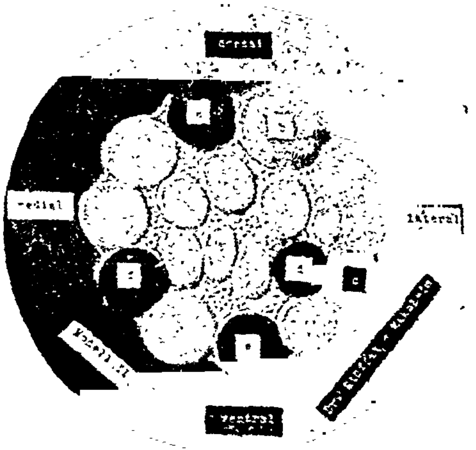

DIAGRAM OF PROXIMAL STUMP OF TIBIAL NERVE IN LOWER HALF OF THIGH

a = the tract forming the communicans tibialis.
b = the tract for the gastrocnemius muscle and the dorsal part of the soleus.
c = the tract for the ventral part of the soleus.
d = the tract for the flexor longus hallucis.
e = the tract for the tibialis posticus.
f = the tract for the flexor longus digitorum.

The rest of the cross-section is made up mostly of the motor tracts for the short flexor muscles and the tracts of the sensory plantar nerves.

He applies the same principle in treatment of sciatica, sifting out the sensory from the motor fibers and severing those which innervate the points where the pain is felt. He refuses to accept a sciatic nerve, saying that there is only a skein of nerve fibers running along the back of the leg to convey motor and sensory impulses. The general picture of sciatica can be resolved into a number of sharply defined clinical pictures which we are accustomed to group and regard as a single morbid entity and call sciatica. He has operated on this principle in a number of cases with unfailing success; all of the patients are permanently cured. In the first case of the kind, after four years of intolerable sciatica there has been no return of the pain during the year since the operation and the pronounced scoliosis has entirely retrogressed.

He gives the patient a blue pencil and asks him to mark on his leg the points where he experiences pain. The drawing thus obtained could not be a more perfect representation of the course of a given sensory nerve if it had been drawn by a skilled anatomist. Stoffel then studies the attitudes of the patient, the positions assumed in standing, walking, sitting and reclining, to learn which positions are assumed to escape the pains. Each of the sensory tracts has its own mechanical conditions, knowledge of which is important for identification of the tract involved. When the nerve tract involved is thus located, he resects it for about 15 cm. and rolls up each stump in turn on forceps until it tears. The sciatica is thus cured while all the motor and all the other sensory tracts are left unmolested.

In the *Munchen. med. Wchnschr.*, June 24, 1913, Stoffel described more in detail his technic for treatment of sciatica (p. 1366). The accompanying illustration is taken from that article. He seeks out the nerve tracts involved by testing the various fibers with a needle electrode, the cathode of a galvanic apparatus, lifting the fibers only by the neurilemma with great care not to injure them, spreading the tracts by working into the delicate connective tissue separating the different tracts of fibers and thus isolating the one involved.

106. **Experimental Syphilitic Lesions Induced by Spirochetes from Brains of Paralytics.**—Berger inoculated twenty rabbits with material from the brains of twenty patients with progressive paralysis. He obtained the material in the form of minute cylinders cut out with a drill and cannula under light general anesthesia. The cylinders were transferred to warm saline and then cut up with scissors, ground in a mortar and injected into the left testicle of the rabbit. The brain was punctured in both frontal lobes and only one of the patients seemed to experience any ill effects; some with a tendency to hydrocephalus were directly benefited by the procedure although the benefit was but transient. In the one unfortunate case, the puncture caused bleeding from a vessel in the cortex and the patient died five days later. He was a man of 51 with advanced paralysis of over two years' standing, and it was learned afterward that he had a history of hemophilia. The inoculation gave positive results in three of the rabbits, confirming the statements that the brain in progressive paralysis shelters living spirochetes, capable of inducing actual—although not very severe—syphilitic lesions in animals. Berger quotes in conclusion Hippocrates' words in regard to the necessity for venturing to a certain extent in the treatment of hitherto incurable diseases as the patients have nothing to lose, while if success should be realized they could be cured.

109. **Laryngeal Tuberculosis No Contra-Indication to Compressive Treatment of the Lungs.**—Zink reports five cases to confirm his assertion that tuberculous laryngitis not only does not contra-indicate therapeutic pneumothorax, but that the latter has a marked beneficial influence on the throat affection. Among his seventy-six patients treated with the compressive pneumothorax, twelve had laryngeal tuberculosis of greater or less severity. The mild forms promptly healed without other measures. Under application of powders or mentholated oil and strict enforcement of the rule of silence, even the four severest cases healed completely. In only one patient did the process resist this treatment, and in this case there were severe intestinal tuberculous lesions. Zink ascribes the benefit to the exclusion of all the factors which cooperate to maintain the laryngeal process, the fever, the progressive course of the pulmonary process and the mechanical injury from coughing and from expectorating and the passage of virulent bacilli in the sputum—all of these factors drop out after the lung has been immobilized by the therapeutic pneumothorax. As the general health improves, the larynx shares in the general uplift. Still another element that must not be overlooked is the fact that the toxins generated in the lungs are not swept throughout the body as before but are retained in the focus; this gives the body a chance to recuperate and augment its resisting powers. Zink regards this transformation of the clinical picture after the artificial pneumothorax as the most important factor in the healing of the lesions. Even ulcerative tuberculous processes in the larynx do not contra-indicate the compressive therapy, but when the process has spread throughout the entire region, involving the epiglottis in the perichondritic process, with edematous swelling and ulceration, relief comes too late at this advanced stage.

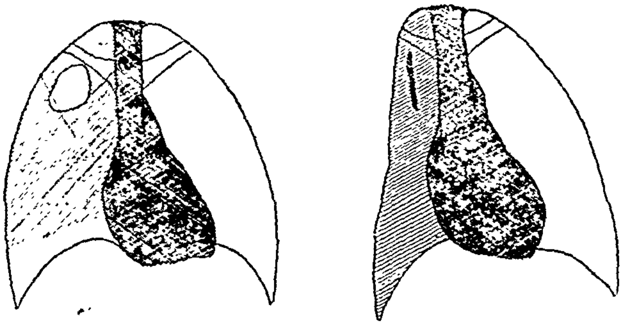
110. **Interval between Acts of Normal Respiration.**—Geigel regards the interval at the end of audible expiration, before audible inspiration begins, as a valuable sign as to whether the respiration is really of the normal type or not. It is often impossible to count the respiration-rate, but it is generally easy to note whether there is this normal pause between expiration and inspiration. There is no interval in febrile conditions; the acts of respiration succeed each other without a pause, and improvement of conditions is often revealed first by the reappearance of the brief interval between the acts of respiration. It can be easily detected even in the dark, and is a valuable aid in the prognosis. Geigel found the interval marked when respiration was 26, 30 or 32 in sick infants, but when the respiration-rate became 42 or 50 there was no interval to be detected. He has coined the term *zäsur* to express this normal interval between the acts of audible respiration.

111. **Serotherapy in Sepsis.**—Bennecke announces that a remarkable turn for the better in five cases of extremely severe sepsis followed intravenous infusion of 210 or 480 c.c. of normal human serum. This occurred with the recovery of the patients in three out of the five cases and transient improvement was obtained in one other case. The infusion had been preceded by venesection in each instance. The patients were between 6 and 20. Necropsy in the fatal cases failed to disclose any ill effects from the procedure.

117. **Surgery of the Lungs.**—Sauerbruch gives the history of operative treatment of diseased lungs, and describes his own experiences in this line with illustrations of his large cabinet for negative atmospheric pressure and his adjustable retractor for enlarging the space between the ribs. He illustrates also other points in the technic as well as concrete examples of its application. He has operated in five cases in which both chest and abdomen were severely injured by crushing from the wheels of a vehicle or between cars. All the patients were saved by the operation. He opened the chest by an incision in the seventh intercostal space, attended to the injury of the lungs and then palpated the abdominal cavity through the diaphragm. The bulging upward of the diaphragm revealed at once hemorrhage below. He cut the diaphragm perpendicular to the direction of the fibers, thus opening up the upper abdomen. The oversight thus afforded is so extensive that removal of the spleen, for instance, by this route is simpler and easier than with a laparotomy.

In case of abscess in the lung, evacuation under differential pressure is a simple and harmless matter. He sutures the lung to the opening in the chest wall over the focus and then opens up the abscess with the actual cautery, sponges out the contents and drains. Very rarely does a fistula develop. Operative treatment has a record of over 70 per cent. of cures (Garré) while Villière was able to find records of only 25 or 20 per cent. cures under internal measures.

Sauerbruch has now a record of 113 cases in which he resected ribs enough to permit the wall of the chest to fall in and thus compress the lung beneath. In seventy-seven of the cases the trouble was of tuberculous origin. Two patients succumbed to the effect of the operation and eleven died from the progress of their tuberculosis months and years later. This group includes five in which the abscess cavity had perforated and there was already severe mixed infection. Of the others, seventeen are practically cured; nineteen much improved, and only four failed to be benefited by the operation, while in three cases the affection seemed to be aggravated. In the group of much improved patients there are six or eight who seem to be on the road to complete recovery. The illustration is drawn from skiagrams of a patient now cured. Note the compression of the lung realized by resection of the bony framework of that side of the chest, and the obliteration of the cavity as the lung is squeezed into smaller compass.



Obliteration of cavity in lung by extrapleural thoracoplastic operation. Patient now cured.

The lesions of bronchiectasia seem to be the least amenable to surgical treatment, but his experience with twenty-five cases showed that although a complete cure was not obtained, yet the great improvement in the general health and reduction in the amount of sputum were very gratifying. On account of the hopelessness of merely internal measures, he thinks that operative treatment should be applied more generally. If it can be done in the earlier stage, the results will certainly improve to correspond.

Sauerbruch thinks that operative treatment of pulmonary tuberculosis has an important future. Progress must be along the lines of improved indications rather than further perfecting of the technic. The compression of the lung and obliteration of the cavity are of importance not only for the patient himself, but as reducing the danger for others. In eight cases Sauerbruch injected a filling when the thoracoplastic operation could not be rendered complete; the patients bore it well and although there were a few complications, yet the end-result was good in all. He emphasizes that these compressive operations on the lungs promise benefit only when the lung process has already showed a tendency to shrivel. The retraction of the lung after the ribs have been resected reduces it remarkably in size, an actual collapse obliterating all the cavities, and thus applying to the lung the principles of rest which are found effectual in treatment of tuberculous processes in bones and joints. The lymph does not circulate through the lung, and there is production of connective tissue to a surprising extent. Again and again he has witnessed the amount of sputum decline from 200 or 400 c.c. a day until finally there is no further expectoration. The fever frequently subsides at once after the operation. In the favorable cases the improvement continues a progressive course to a complete cure. He gives illustrations of the technic with which he resects, from the back, the ribs from the first to the eleventh, operating at one or two sittings. It is sometimes possible to resect the ribs merely directly over the cavity; Sauerbruch recommends for this a preceding therapeutic pneumothorax to compress the lower lobe when the cavity is in the upper. By selection of cases, by operating under local anesthesia, and with great attention to the after-care, he says that we can recommend this extra-pleural thoracoplastic method of treating tuberculous cavities in the lungs as a harmless intervention. Most of his patients were between 16 and 25, but others were up to 40 years old.

121 *Electric Accidents. (Zur Kenntnis der Unfälle durch Elektrizität.) F. Fischl.

121. **Electric Accidents.**—Fischl reports a case in which a young electrician dropped to the ground unconscious as a short-circuited current of 5,000 volts passed from one hand to the other. Although the heart was on the route of the current, yet little injury followed; after brief bradycardia there was arhythmia but the pulse returned to normal the second day under digitalis, and there was not even abnormally high blood-pressure the morning after the accident. The electric burn of the hand was comparatively insignificant, a grayish line running through it resembling an old knife cut well on the way to healing. Consciousness returned after half an hour and the patient complained of headache and great sensitiveness to light, even with the eyes shut. There were also much depression, weakness and somnolency, with paralytic conditions in the muscles, but recovery was soon complete as the burns on the legs healed. Professional electricians do not seem to have to contend with the psychic shock usual under other conditions.

124 *Primary Carcinoma of Fallopian Tube. J. Fonyo.

124. **Primary Tubal Cancer.**—Fonyo states that only 120 cases of cancer of the Fallopian tubes have been reported since 1886 in German, French and English literature, but he has encountered at Budapest two additional cases which he here describes in detail. He thinks that primary tubal cancer is more frequent than the literature would suggest. Comparatively few tubes removed for various reasons are examined for cancer; if this were done more frequently the number of cases of tubal cancer would certainly increase. His two patients

were in the fifties, and both had passed through three pregnancies. He compares the findings with those in cases on record, and states that the possibility of cancer is an argument for panhysterectomy in all dubious cases of disease in the uterine adnexa, *removing at the same time the regional* lymph-nodes. The bad outcome in the operative cases to date is due mainly to the lack of thoroughness in the operation and to the late stage at which the diagnosis was made.

128 *Suture of the Heart. (Sulle ferite del cuore.) N. Leotta. Commenced in No. 7.

126. **Method for Reducing Lumen of Blood-Vessel.**—Scalone runs a curved needle through the superficial layers of one side of the wall of the vessel, then introduces it again at a distance beyond. By drawing up the ends of the thread, the wall between the two stitches is forced inward and the lumen is obstructed to that amount. By taking the stitches farther apart, the fold thus forced inward can be made as large as desired. If the suture thread pulls out, this is readily remedied by taking another stitch beyond. The special advantage of the technic is that the maneuver can be done without first shutting off the blood in the vessel, and the vessel does not have to be isolated. The technic can be applied just as well whether the vessel is detached from its bed or not. It is harmless, and the amount of stenosis can be graduated as desired. The same procedure can be repeated above and below as needed to operate on as long a segment of the vessel as desired. The obstruction is maintained by the natural tissues without extraneous substances in contact with the interior of the vessel.

128. **Operative Treatment of Wounds of the Heart.**—Leotta gives statistics which show recovery in 44.91 per cent. of 236 cases in which the heart was sutured. When the left ventricle was the seat of the injury, 46.29 per cent. of the 108 patients recovered; 39.28 per cent. of the eighty-four patients with the wound in the right ventricle; 77.77 per cent. of the nine with the wound in the left auricle, and 62.5 per cent. in the right auricle. One patient with both left auricle and ventricle injured died, and one of the two with both right auricle and ventricle injured. In thirty-five of the total 236 cases, the injury had been done with a firearm. The proportions of recovery with this were about the same as above except that both of the two patients recovered who had both the right ventricle and auricle or the left ventricle and auricle injured.

132 *Neurosis of the Stomach or Duodenal Ulcer? (Maagneurose of ulcus duodeni.) M. A. de Kock.
133 *Anencephaly. B. Brouwer.

130. **Changes in the Brain with Cirrhosis of the Liver.**—In the case described with five illustrations an increased amount of glia fibers were found in the cortex and also increased numbers of glia cells. No signs of acute inflammation were detected. Very little seems to have been done along this line of neurologic examination of the brain in disease of the liver, and yet this may prove a rich field for investigation.

132. **Gastric Neurosis or Duodenal Ulcer?**—De Kock says that the rarity of cases of perforated duodenal ulcer in the Netherlands is due to the general ignorance of the existence of the chronic duodenal ulcer. No diagnosis of it is made. The Netherlands medical profession is still influenced by the German conception that the accompanying hyperacidity and other symptoms are due to a nervous affection of the stomach, and that there is no need to seek for an organic lesion. The Americans and the English, he states, have been pioneers in the recognition of ulceration in the duodenum, and de Kock hopes that their views may speedily be accepted in his country, and that the profession will not wait until the proper appreciation of duodenal ulcer has had to filter to them through German channels first.

133. **Anencephaly.**—Brouwer's illustrated article contains a histologic description of the central nervous tissues in a typical anencephalus. Also a carefully prepared outline for physiologic examination of living monsters of this kind; he specifies twenty-eight points to be recorded, including the behavior of the various reflexes and the response to the Wassermann test. Brouwer adds further a number of interesting physiologic deductions from the data presented, especially in regard to the elementary functions of the nerves. He regards the movements of an anencephalus as mostly of the nature of reflex movements; in his case the brain had evidently failed to develop properly on account of some local inflammatory process affecting the fetus.

142. **Epidemic Meningitis.**—Penna seems to be quite successful with his method of treating epidemic cerebrospinal meningitis. He generally applies wet cups along the spine, with ice to the head, and purges with calomel sometimes giving also 1 gm. of potassium iodid and mercurial inunctions, as in syphilis. He applies lumbar puncture at need, and antimeningococcus serotherapy. His mortality was 32 per cent. in 200 cases of meningitis in which he injected the antimeningococcus serum into the spinal canal by lumbar puncture. Of late, he has supplemented this by intravenous injection of some of the 100 c.c. of the serum, *his maximum dose.* He reports a few cases in which the entire dose was injected into a vein, apparently attenuating the disease and hastening recovery. A second injection, twenty-four hours later, was sometimes given with a little smaller dose. He lays great stress also on hygiene of the mouth in the care of meningitis patients.

RADIOGRAPHIC STUDIES OF THE GASTRO-INTESTINAL TRACT IN INFANTS *

HENRY DWIGHT CHAPIN, M.D.
NEW YORK

The difference between a dissection of the body in studying various viscera and organs and the modern Roentgen examination of the same parts will often show quite a field of divergence. The great advantage of the latter method is, of course, that it is dealing with the living and functioning body. Not only are the positions and relations of the organs liable to be somewhat different in life and death, but the mobility and motility of the viscera can be studied by the new method.

This has a practical side, as we are learning that some conclusions drawn from pure anatomy cannot hold entirely good in treating the living body. This is especially true at the beginning of life, when function and form may show wide variations. It will doubtless be necessary for many studies to be made by different observers, with a subsequent comparing of results, before generalizations can safely be made in reference to the limits of location, mobility and motility of the various viscera studied by means of the Roentgen ray. It opens up a promising field of research, however, and we have learned enough already to change our beliefs somewhat as to the form and functioning of the different parts of the gastro-intestinal tract.

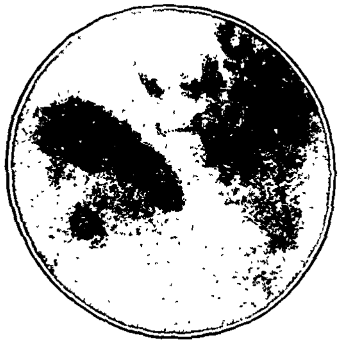

Fig. 1.—Fifty-five minutes. Stomach horizontal, as observed by the recent studies of Pisek and Le-Wald. Greater portion of barium in the stomach; considerable amount in the small intestines.

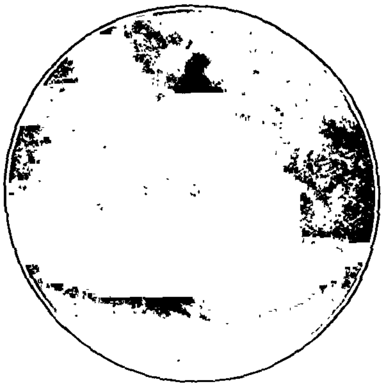

Fig. 3.—One hour and fifty minutes. Small amount of barium in the stomach. The rest of the barium in the small intestines, possibly some in the cecum.

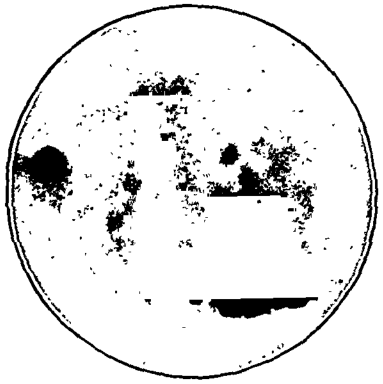

Fig. 5.—Three hours and ten minutes. A trace of barium in the stomach; moderate amount of barium in the small intestine. Cecum, ascending colon and hepatic flexure almost completely filled, with greater part of barium in these situations.

In the present study, two cases were observed in reference to the rapidity with which a suspension of barium sulphate could travel from the stomach to the cecum and thence through the large intestine to the outlet of the body.

CASE 1.—James L., aged 8 months, weight 14 pounds, 6 ounces. Physical examination negative. Admitted to the hospital for observation as he had had three convulsions several days before. The evening preceding the experiment he was given a dose of castor oil to clear the bowel, and feedings of dextrinized barley gruel started, which were continued through the experiment. The object of stopping milk and giving a fairly soluble food was to avoid possible hard curdling or any digestive disturbance that might interfere with the progress of the barium. At 9:30 a. m. he was given a meal consisting of a heaping teaspoonful of barium sulphate in 8 ounces of acacia by the stomach-tube. An ordinary Roentgen-ray tube was used with an intensifying screen and length of exposure one-tenth second. The infant was placed on the face and abdomen, with arms and legs extended, and Roentgen tube 14 inches from the plate.

A comparison of all the figures shows that up to Figure 5 (three hours and 10 minutes) there is very little gas in the colon. After this time there is considerable gas in the ascending colon and hepatic flexure as well as in the splenic flexure and descending colon. Seven hours after the barium meal the gas begins to disappear from the whole colon, apparently simultaneously with the evacuation of the barium column from the colon into the rectum.

CASE 2.—William J., 7 months, weight 14 pounds, 4 ounces. Physical examination negative. Sent to hospital for loose bowels. This condition was relieved and when the pictures were taken the bowels were constipated with stools rather hard and infrequent. A dose of castor oil was given in the

* Chairman's address before the Section on Diseases of Children of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

* Because of lack of space, this article is abbreviated in THE JOURNAL by omission of some of the illustrations. The complete article appears in the Transactions of the Section and in the author's reprints.

evening followed by dextrinized barley gruel feedings as before. At 9:30 a. m. a heaping teaspoonful of barium sulphate in 8 ounces of mucilage of acacia was given by the stomach-tube.

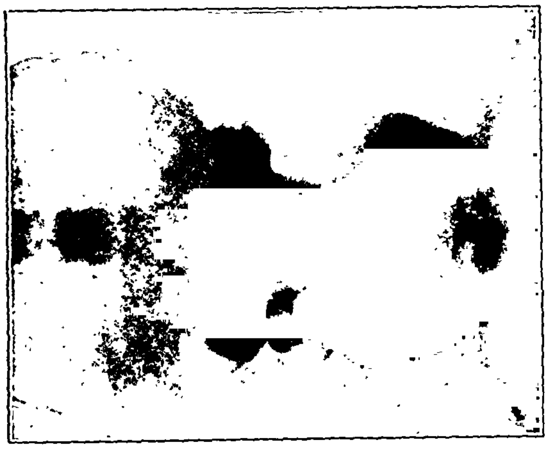

Fig. 8.—Six hours. Cecum, ascending colon and transverse colon to the splenic flexure well distended with barium. Small amount of barium in the sigmoid.

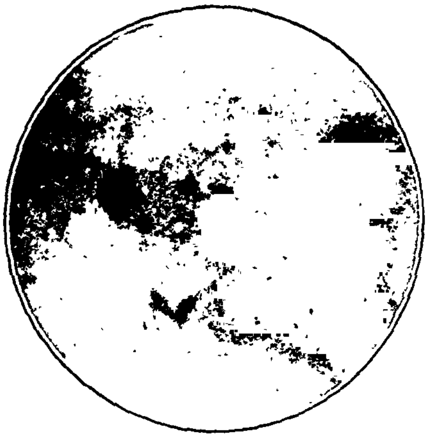

Fig. 9.—Seven hours. Some residue of barium in the cecum. Greater part of the barium has disappeared from the ascending and transverse colon. A considerable amount of barium in the descending colon. Rectum well distended with barium.

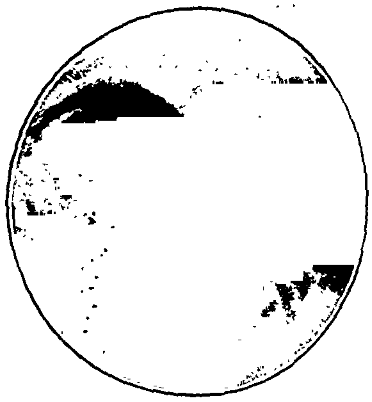

Fig. 10.—Twenty minutes. Stomach horizontal. Very remarkable in that a noticeable amount of barium is already in the small intestine.

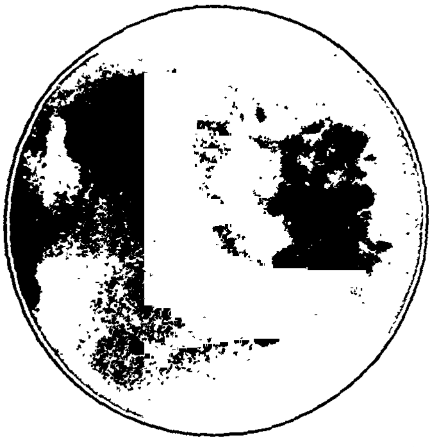

Fig. 12.—One hour and forty minutes. Stomach contains a small amount of barium. Still a considerable amount of barium in the small intestines. Ascending colon, hepatic flexure and a part of the transverse colon contain barium.

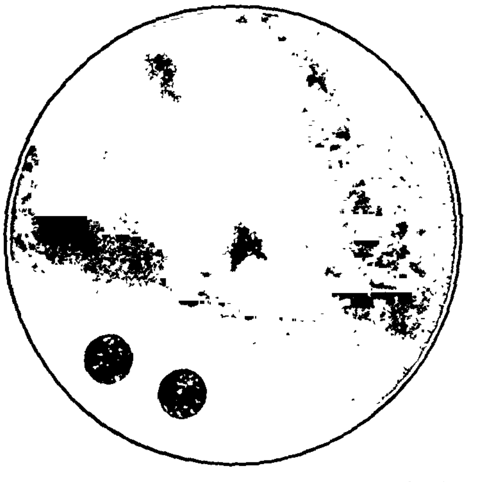

Fig. 14.—Two hours and thirty minutes. Small amount of barium in the stomach. The entire small intestine contains some barium. Cecum well filled with barium and the hepatic flexure, ascending and transverse colon, splenic flexure and first third of the descending colon contain barium.

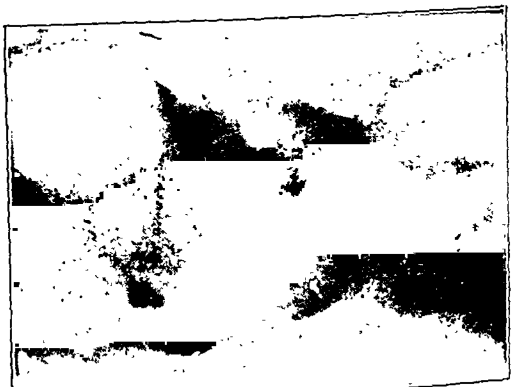

Fig. 17.—Six hours. A considerable amount of gas in the stomach. Cecum, ascending colon and hepatic flexure well distended with barium. Transverse and descending colon empty. Sigmoid flexure and rectum filled with barium (defecation). This suggests that reverse peristalsis may take place when cecal digestion is not as yet complete.

These two experiments were made on infants of about the same age, weight and general development. In seven hours the barium meal had traveled through the gastro-intestinal tract, as most of the barium column was then evacuated from the colon into the rectum. The end of the barium column is, of course, the measure of the motility of the bowel. It must be remembered, also, in these and similar experiments, that foreign bodies, like bismuth and barium, are undoubtedly expelled from the stomach and pass along the intestines more rapidly than normal food. The use of the carbohydrate base tends to prevent interference with stomach acidity.

An interesting account is given by Holzknecht[1] of studies made by him on the motions of the bowel by means of a fluorescent screen. He found that the normal progress of the contents of the duodenum and small intestine is by intermittent, irregular and rapid little jets or jerks. "A cylinder of chyme will be formed, the size of a small coin in section and a finger in length. This will be driven forward for a few seconds at intervals of a minute or two. The suddenness of the movement stretches the intestinal tube, the valvulae conniventes stiffen, and their edges break up and rotate the fluid stream." He further calls attention to the fact that hardly any one has seen the normal peristalsis of the colon. Such peristalsis takes place suddenly, lasting only for a few seconds and occurs at long intervals. He finds, with Stierlin, that these jerks occur from six to eight times in twenty-four hours, the number of displacements varying with different individuals. One case was mentioned in which the whole transverse colon was emptied into the descending colon in three seconds as seen by the fluoroscope.

A third series of cases was studied after a clysma of barium had been given. The location and form of the sigmoid flexure was noted with special reference to the possible passage of tubes. Attention was also given to the distensibility of the colon, the form and situation of the splenic and hepatic flexures, and the patency of the ileocecal valve. Ten infants were thus studied, with thirteen pairs of plates, so that stereoscopic views could be procured. The ages were as follows: 2 months, 9 weeks, 3 months, 4 months, 7 months, 8½ months, 9 months, 13 months, 18 months and 25 months. An ordinary Roentgen-ray tube was used, as before, with an intensifying screen and length of exposure one-tenth second. Each infant received half an ounce of castor oil four hours before the clysma and was afterward fed with barley water until after the experiment. Eight drops of paregoric were given half an hour before the injection and the rectum painted with a 2 per cent. cocain solution just before administering the barium clysma. This was found helpful in controlling the bowels. Four heaping teaspoonfuls of barium sulphate to each 8 ounces of acacia were injected and the amount retained varied from about 4 to 16 ounces. The feet were held higher than the head and the tube inserted about 4 inches into the rectum, while the funnel through which the barium mixture passed was held about 18 inches above the child. The buttocks were then held tightly together until after the picture was taken. Little barium was usually retained if these precautions were not observed.

---

[1] Holzknecht, G.: Berl. klin. Wchnschr., 1911, xlviii, No. 4, translated in Arch. Roentg. Ray, July, 1912.

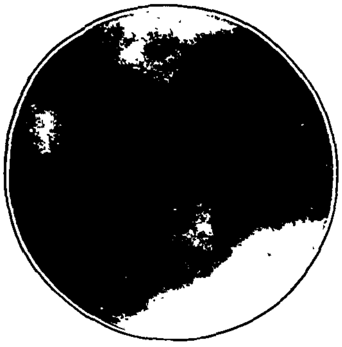

Fig. 18.—Seven hours. Cecum, ascending colon and first third of descending colon empty. Transverse colon filled near splenic flexure, which is nearly empty. Rest of descending colon, sigmoid flexure and rectum filled.

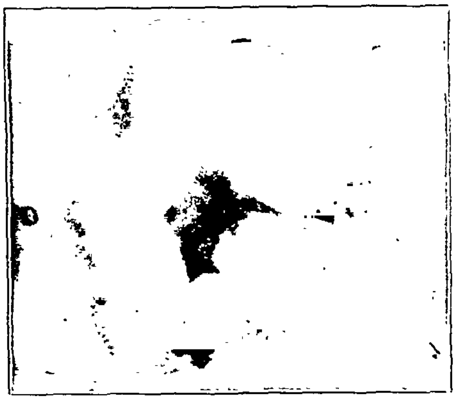

Fig. 19.—For description see Experiment 1.

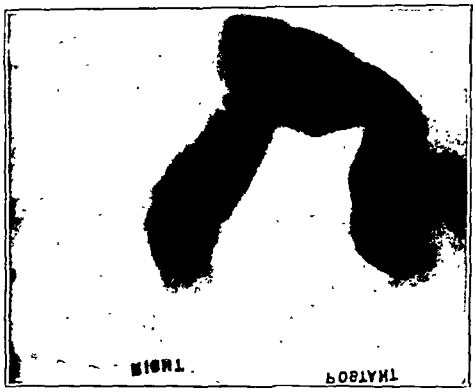

Fig. 20.—For description see Experiment 2.

The picture was begun right after the injection, averaging about half a minute, the child held face downward on its abdomen and the tube 14 inches from the plate.

The results shown in Experiments 1 to 13 were noted:

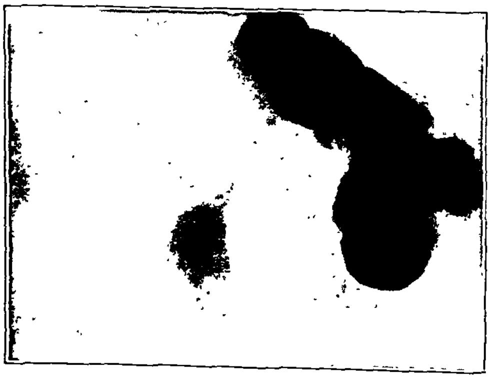

Fig 21.—For description see Experiment 2.

Experiment 1 (Fig. 19).—Colon entirely filled, holding 16 ounces. Sigmoid flexure above the umbilicus and falls to the left.

Experiment 2 (Fig. 20).—Rectum, sigmoid flexure, descending colon, splenic flexure and transverse colon filled. Hepatic flexure, ascending colon and cecum outlined with feces, gas and streaks of barium.

Experiment 2 (Fig. 21).—Picture taken fifteen seconds after Figure 20. A peristaltic wave is seen in the transverse colon. The bowel holds 16 ounces. Sigmoid flexure is well above the crest of the ilium, and has fallen over to the right.

Experiment 3.—Colon entirely filled. Holds 8 ounces. Sigmoid rises as high as the transverse colon and lies in the form of a figure S.

Experiment 4.—Colon completely filled, holding 16 ounces. Ileocecal valve patent. Sigmoid rises above the umbilicus and shows a complete twist.

Experiment 5 (Fig. 24).—Colon completely filled and some barium in small intestine. Holds 8 ounces. Sigmoid passes nearly to umbilicus then downward to the left.

Experiment 6 (Fig. 25).—Colon, sigmoid and rectum filled. Splenic flexure and lower third of descending colon partly filled. Transverse colon and upper two-thirds of descending colon show streaks. Sigmoid rises to umbilicus and then downward and to the left. Holds only about 2 ounces.

Experiment 7: Cecum empty. Ascending colon partly filled. Bowel filled from hepatic flexure to rectum. Holds 16 ounces. Sigmoid rises to level of umbilicus and falls to right.

Experiment 8: Splenic flexure, descending colon, sigmoid and rectum filled. Ascending colon, hepatic flexure and transverse colon show streaks. Holds only about 4 ounces. Sigmoid rises to crest of ilium and turns to left of descending colon.

Experiment 9: Lower half of descending colon, sigmoid and rectum filled. Above this, streaks, up to hepatic flexure and the rest empty. Sixteen ounces injected but most all expelled. Sigmoid rises above umbilicus and falls to right.

Experiment 10: Colon entirely filled from hepatic flexure to rectum. Cecum and ascending colon obscured from sigmoid lying in front. Transverse colon shows peristaltic wave. Sigmoid far to the right, carrying with it the descending colon, apparently due to a long mesocolon. Holds 16 ounces.

Experiment 11: Colon filled, but cecum obscured by sigmoid. Sigmoid rises in front of cecum and above umbilicus almost to transverse colon and then falls to the right. Holds 16 ounces.

Experiment 12: Colon filled but sigmoid obscured. Holds about 8 ounces.

Experiment 13: Colon only partly filled as most of the barium was expelled and picture obscured. In this case the precautions of giving the opiate and cocain to the rectum were not carried out.

It is seen that in these cases there was much difference in various parts of the colon as regards mobility. The hepatic flexure, transverse colon and sigmoid flexure showed the greatest variability. Any injected substances that get past the sigmoid flexure reach the cecum very quickly, and without using much force, as these pictures were taken not more than a minute after the clysmas were given. In one of the cases (Fig. 24) the ileocecal valve was patent, the barium being distinctly seen in the small intestine, and in another case it was doubtful put probable. Dr. James T. Case[2] reports that out of a series of 200 gastro-intestinal cases 33 showed the ileocecal valve incompetent as determined by the barium clysma. Kraus found the ileocecal valve incompetent in only 12 cases out of 150 examinations. He states that the ileocecal valve is patent in new-born infants. This is a subject that warrants future study.

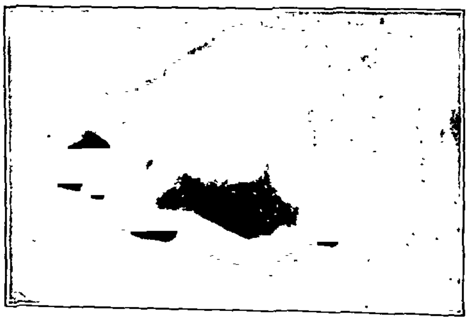

Fig. 24.—For description see Experiment 5.

A study of the sigmoid flexure in these cases showed remarkable variations both in form and situation. This structure seems to occupy greater space than has hitherto been supposed. The previous notes show how twisted and doubled-up in all directions it may be during life and how it may occasionally reach as high as the transverse colon.

---

[2] Case, James T.: Am. Quart Roentgenol., November, 1912.

From these and other studies it is evident that it is rarely, if ever, possible to pass a tube through this structure. Nothnagel and Boas, years ago, held that a tube could not be made to pass the sigmoid, and later Lilienthal, in 1906, verified this fact by roentgenograms. The tubes could be passed only to the bend or apex of the sigmoid flexure, when they impinged on the wall, the long mesentery of the sigmoid stretching out like a fan, permitting no further progress. Still later, Soper[3] reported sixty cases in which the position of the tube was verified by radiographs and the tube was always found coiled up in a dilated rectum. In only one case was he able to introduce a tube higher than the dome of the rectum and this proved to be Hirschsprung's disease. The last illustration here shown is an example of this congenital dilatation and hypertrophy of the colon. In Figure 25 the transverse colon has sagged into the pelvis.

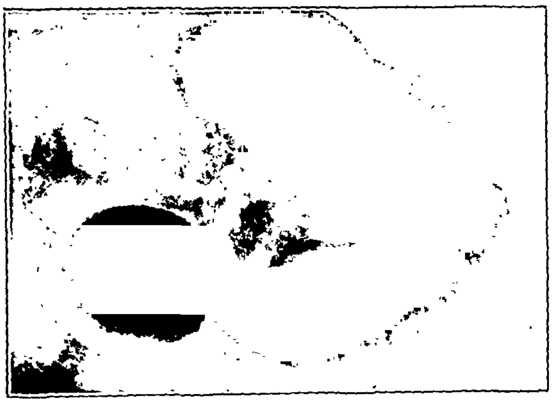

Fig. 25.—Congenital dilatation and hypertrophy of colon.

In making these experiments I am much indebted to Dr. Marshall C. Pease for preparing and observing the cases, to Dr. Lewis for taking the pictures in the Roentgen-ray laboratory of the New York Post-Graduate Hospital, and also to Dr. Kast in aiding in an interpretation of the plates.

51 West Fifty-First Street.

USE OF THE ROENTGEN RAY IN THE DIAGNOSIS OF OBSCURE ABDOMINAL CONDITIONS IN INFANCY AND CHILDHOOD *

JOHN LOVETT MORSE, A.M., M.D.
Associate Professor of Pediatrics, Harvard Medical School; Associate Visiting Physician at the Children's Hospital and at The Infants' Hospital
BOSTON

I have been much impressed, during the last two years, by the assistance given by the Roentgen ray in the diagnosis of obscure abdominal conditions in infancy and childhood. It not only bids fair to settle definitely the time required for the emptying of the infant's stomach under normal conditions and the effect of the various foodstuffs and salts on this time, but also to be of the greatest value in determining the presence and nature of pathologic abdominal conditions in early life. It has in many instances, in my experience, afforded information which could not have been obtained in any other way, and has made the diagnosis easy in conditions the nature of which could only have been guessed at in the absence of this information. It makes a positive diagnosis easy in many obscure cases, and in many others reveals abnormal conditions which without it would be entirely overlooked.

I shall not attempt to enumerate all the conditions in which the Roentgen ray may be of assistance in diagnosis, but shall merely mention a few in which I have myself found it useful.

It is often extremely difficult to distinguish between chronic gastric indigestion, spasm of the pylorus and stenosis of the pylorus in early infancy on the basis of the history and physical examination. The Roentgen ray is of the greatest assistance in differentiating between these conditions and not infrequently gives information in a few hours which could not be obtained in any other way for days or even weeks. It shows conclusively how soon the food begins to leave the stomach, how rapidly it leaves and how long it is before the stomach is empty. The following cases show its value in the diagnosis of these conditions:

Case 1.—J. M., boy, was born at full term, after a normal labor, and was normal at birth. He was entirely breast-fed and his mother apparently had plenty of milk. He began to vomit when a little over 2 weeks old, the vomiting occurring after every feeding. The amount of the vomitus was at first small, but soon became large. He sometimes vomited while taking the breast, but at other times not until after an hour or more. He at times did not vomit until after the next feeding, when he vomited a large amount. The vomiting eventually became projectile. Changing the intervals between the nursings had made no difference in the vomiting. Barley-water was vomited the same as the breast milk, and during the last four days even water had been vomited. The stools

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

* Because of lack of space this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints. A copy of the latter will be sent by the author on receipt of a stamped addressed envelope.

were normal in amount and character during the first three weeks, but since then they had been small, green and slimy. The bowels had not moved during the last three days. He had passed very little urine for two weeks, and had lost weight very rapidly. He was seen when 6 weeks old.

Physical examination showed a fairly developed and nourished baby, of fair color. The fontanel was depressed and the bones of the skull overlapped a little. The abdomen was sunken. The stomach extended 3 cm. below the navel. Marked waves of peristalsis were seen running from left to right after nursing. The baby then had spasms of pain, followed by retching and vomiting. The vomiting was not explosive. No tumor was felt either before or after the vomiting. During the examination he passed a partially formed, medium-sized, greenish-brown stool, which contained considerable mucus, but no definite food elements.

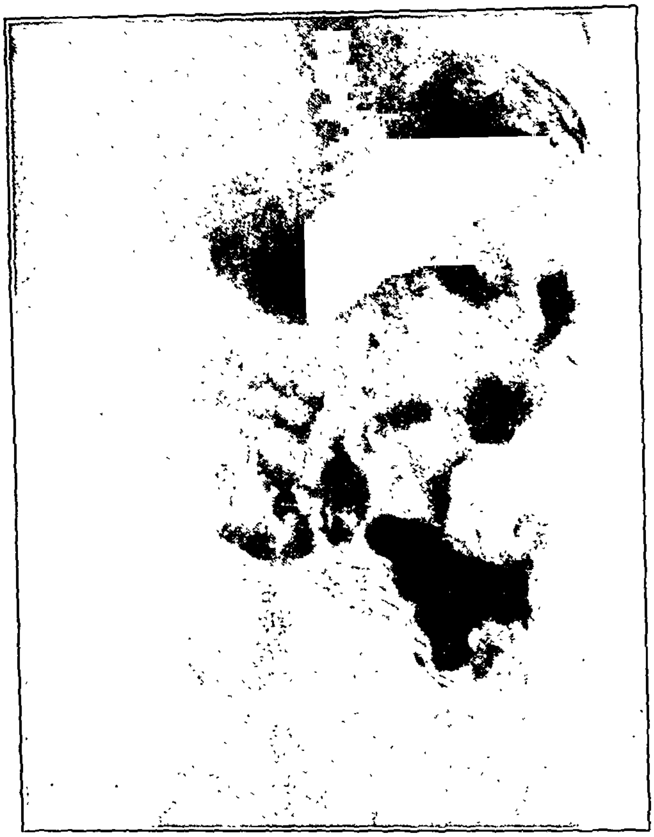

Fig. 4.—Case 2. Taken forty minutes after a bismuth meal.

The history in this instance was characteristic of stenosis of the pylorus. The absence of a palpable tumor and of explosive vomiting pointed, however, to spasm of the pylorus. Chronic gastric indigestion was, of course, out of the question. A roentgenogram (Fig. 1) taken immediately after a bismuth meal showed no food leaving the stomach. Repeated pictures, taken at first every fifteen minutes and then every half-hour until six hours (Fig. 2) had elapsed, showed that nothing whatever left the stomach during this time. Many of them, moreover, showed definite indentations of peristalsis. He was allowed to nurse ten minutes before the last picture was taken, because feeding will sometimes stimulate peristalsis and cause the stomach to empty itself. These pictures at once established the positive diagnosis of stenosis of the pylorus.

Case 2.—W. B., boy, weighed 8 pounds at birth. He was nursed for ten weeks, when he was weaned on account of persistent vomiting. A Mellin's Food mixture, equal parts of fat-free milk and barley-water, to which lactose was added, a mixture of fat-free milk and boiled water, to which dextri-maltose was added, and whey were also vomited. He had recently been given eight feedings of 2 or 3 ounces. He vomited immediately after every feeding, although he did not always vomit all that he took. The food was vomited practically as it was taken. He had never vomited a larger quantity at one time than the amount taken at the last feeding. He usually did not vomit more than once after each feeding, but at times vomited several times between feedings. The vomiting had never been explosive. It was, however, often associated with pain. The bowels were constipated, but with the help of milk of magnesia and suppositories he had had one fair-sized, yellow, well-digested movement daily. He had regained his birth-weight in two weeks, but since then had gradually dropped to 6¾ pounds. He was seen when 3½ months old.

He was well developed, but emaciated. The fontanel was depressed. After feeding, the stomach was clearly visible in the epigastrium. The lower border was 1 cm. above the navel, the level above that of the thorax. There was questionable peristalsis, but no tumor was made out when the stomach was either full or empty.

A roentgenogram (Fig. 3), taken immediately after a bismuth meal, showed no bismuth leaving the stomach. One taken forty minutes later (Fig. 4) showed, however, that a considerable portion of the meal had left the stomach. It also showed marked indentations of peristalsis. One, taken at the end of two hours, showed that the stomach was empty. These pictures proved conclusively, therefore, that there was no organic stenosis of the pylorus and that the symptoms were due either to spasm of the pylorus or to a disturbance of the digestion. The development of the vomiting on breast-milk and the persistence of the vomiting on a reasonable diet, together with the visible persistalsis and the marked indentations of the stomach wall shown in the roentgenograms, proved that the case was one of spasm rather than of indigestion.

Case 3.—M. C., girl, weighed 7 pounds at birth. She had been nursed from the beginning. She was given the breast for fifteen minutes every two and one-half hours by day and twice during the night. She had vomited after every feeding since she was a week old. The vomiting sometimes occurred immediately, sometimes about an hour after feeding. The vomiting had not been explosive and she had never vomited more than she had taken at the last feeding. She was apparently always hungry and never satisfied. She had had one smooth, yellow stool daily. Her weight when she was seen, when 2 months old, was a little less than 8 pounds.

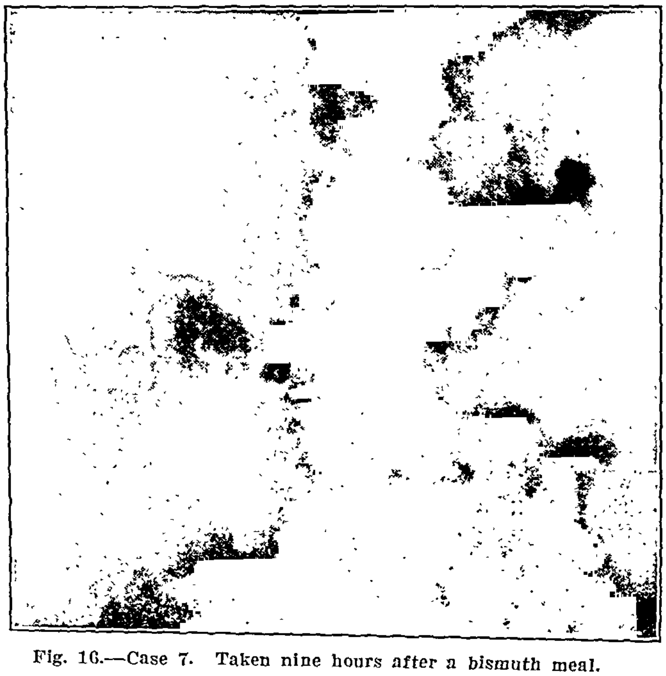

Fig. 16.—Case 7. Taken nine hours after a bismuth meal.

She was fairly developed and nourished, but rather pale. The fontanel was level. The abdomen was soft, there was no visible gastric peristalsis and no tumor was felt in the region of the pylorus.

A roentgenogram (Fig. 5) taken immediately after a bismuth meal showed that the food was already beginning to leave the stomach, while one (Fig. 6) taken fifteen minutes later showed that a considerable amount had already passed through the pylorus. The symptoms in this instance, while pointing more strongly to gastric indigestion than to any more serious condition, were suggestive enough of pyloric spasm or stenosis to cause considerable anxiety. The roentgenogram excluded the more serious conditions within fifteen minutes.

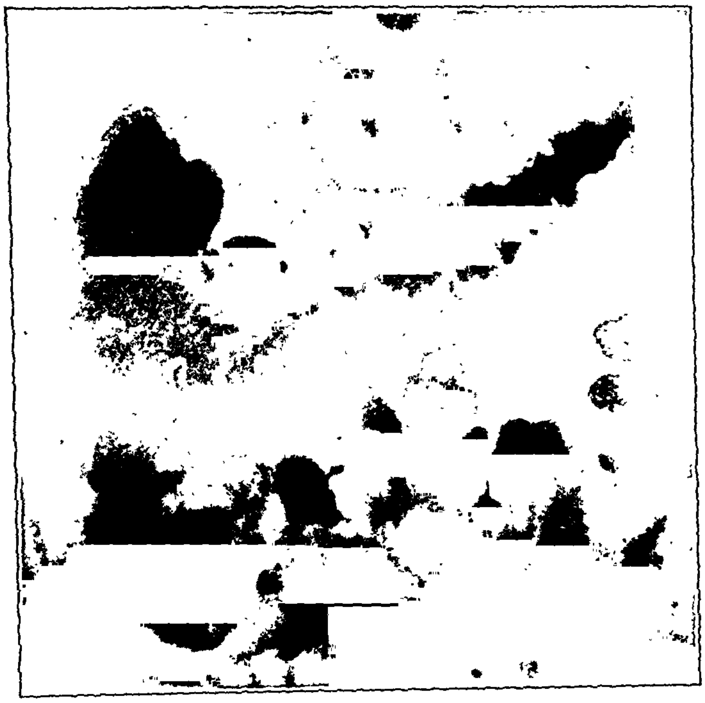

Fig. 17.—Case 7. Taken twenty-four hours after a bismuth meal.

There is probably no class of cases in childhood in which the diagnosis is more difficult than that in which there are recurrent attacks of vomiting and abdominal pain, either singly or in combination. In this class of cases also the Roentgen ray furnishes evidence of the greatest importance and in many instances discloses the cause of the symptoms. It not infrequently reveals conditions which could not be determined in any other way. The following cases are illustrative of this class.

Case 4.—A. C., boy, aged 6½ years, had had recurrent attacks of vomiting ever since he was weaned. They had come at first once in six or eight months, but recently every few weeks. The attacks began suddenly with pain in the region of the navel. The pain was more or less continuous. Vomiting always began in less than an hour and persisted. The attacks were always associated with constipation and were relieved when the bowels were thoroughly emptied. They lasted from thirty-six hours to ten days. He was sometimes so weak toward the end of an attack that he did not recognize his parents. He was circumcised in April, 1912, because it was thought that reflex irritation from phimosis might be the cause of the attacks. A diagnosis of recurrent vomiting from acid intoxication was made in one of our hospitals in October, 1912, because of the presence of acetone in the urine and breath. His appendix was removed in another hospital in December, 1912, during one of these attacks. They, nevertheless, persisted. He was seen in February, 1913.

He was well developed and fairly nourished. The level of the abdomen was a little below that of the thorax. It was soft and tympanitic. There were no evidences of fluid, no masses were felt and there was no spasm. There was a little tenderness on deep pressure in the left upper quadrant. Rectal examination showed nothing abnormal.

A roentgenogram (Fig. 7) taken while he was lying down, immediately after a bismuth meal, showed that the lower border of the stomach was on a level with the crests of the ilia. Another (Fig. 8), taken six hours later, showed the lower border of the stomach still lower, with considerable bismuth still in it. One (Fig. 9), taken twenty-four hours after the meal, showed the stomach free from bismuth and the colon filled with it. The upper margin of the transverse colon was at the level of the navel. Still another (Fig. 10), taken after a bismuth enema, showed a marked prolapse and consequent kinking of the large intestine.

The attacks were evidently due, therefore (Figs. 7, 8, 9 and 10), to temporary intestinal obstruction, resulting from splanchnoptosis. This condition could not have been recognized in any other way. If the Roentgen ray had been used earlier he would have been spared two unnecessary operations.

Case 5.—I. R., girl, aged 10½ years, had always been constipated, but had otherwise been very well. She had had repeated attacks of very severe pain in the lower abdomen since the middle of December, 1912. The pain lasted from ten to fifteen minutes and was so severe that she cried out, pulled her hair and lay down and writhed about. The pain stopped suddenly and she then had a strong desire to urinate. She sometimes had four or five attacks in a day, but at other times went as long as a week without one. The attacks were followed by dull pain in the lower abdomen for about twenty-four hours. She had been more constipated since these attacks began, sometimes, in spite of cathartics, going a week without a movement. She was seen early in March, 1913.

She was well-developed and fairly nourished. Her tongue was clean. The level of the abdomen was that of the thorax. It was soft, no masses were felt and there were no evidences of fluid. There was slight tenderness on deep palpation in the median line below the navel. There was no tenderness in the region of the kidneys, and they were not palpable. The rectal examination showed nothing abnormal. The urine was of normal color, acid in reaction, and contained no albumin. The sediment showed nothing abnormal.

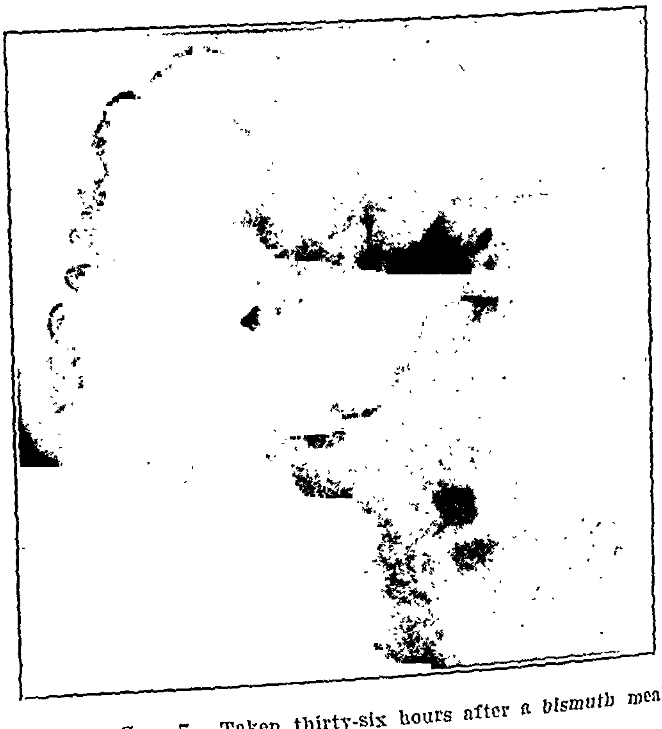

Fig. 18.—Case 7. Taken thirty-six hours after a bismuth meal.

The symptoms suggested a stone in the bladder more than anything else, although it was evident that the pain might be due to interference with intestinal peristalsis from any one of many causes. Roentgenograms, taken one-half hour (Fig. 11) and two and three-quarter hours (Fig. 12) after a bismuth meal, showed that the stomach was in the normal position and that it emptied itself with normal rapidity. They showed no evidences of stone in either the kidneys or bladder. Another (Fig. 14), taken six hours after a bismuth meal, showed all the bismuth in the cecum and lower third of the ascending colon, proving that there was no interference with the passage of food through the small intestine. One (Fig. 14), taken twenty-four hours after a bismuth meal, showed the cecum and ascending colon empty, while the transverse and descending colon were full of bismuth. The hepatic flexure was only a short distance above the crest of the ilium and the transverse colon sagged down in a V-shape, so that the lowest portion reached nearly to the pubes. The transverse colon was also considerably distended. A roentgenogram taken after a bismuth enema showed the same condition.

The attacks of pain were evidently due therefore (Figs. 11, 12, 13 and 14), to the interference with the intestinal peristalsis resulting from the malposition of the colon, not to a stone in the bladder, peritonitis or pressure on the bowel from the outside.

Case 6.—H. E., girl, aged 9½ years, began two years before, to have acute attacks of pain in the abdomen. These attacks occurred about once in two weeks and lasted about an hour. Vomiting gave immediate relief. There was no apparent relation between the ingestion of food, urination or defecation and these attacks. She continued to have them at irregular intervals for four months. During the next summer she had no attacks, but during the following winter they were more severe and occurred at more frequent intervals. She had no attacks during the following summer and was well until the middle of February, when the attacks again recurred. They were more severe than before and the pain was more definitely located in the left half of the abdomen. During the next month she had two or three attacks a week, the attacks lasting from one-half hour to five hours. Emesis from mustard-water immediately relieved them, but nothing else did. The bowels often moved and she often passed urine during the attack without any relief. She was never jaundiced after the attacks and there was no increased frequency of micturition or trouble in passing urine during the attacks. They were not associated with fever. She was seen, in an attack, the middle of March. She lay on her back, writhing with pain, with her legs drawn up and her face pinched. The left upper quadrant of the abdomen was held very tense and there was tenderness in this region. She was immediately relieved by emesis after the ingestion of mustard-water. The tenderness and spasm in the left upper quadrant of the abdomen at once disappeared.

The patient looked perfectly normal in every way. The level of the abdomen was that of the thorax. There was no muscular spasm, no masses were felt and there was no tenderness. The kidneys were not palpable. The liver and spleen could not be felt. The knee-jerks were present and equal. The pupils reacted to both light and accommodation.

The location of the pain, the instant relief after vomiting, and the absence of urinary symptoms pointed strongly to the gastro-enteric tract as the cause of the symptoms. A series of roentgenograms showed, however, that the stomach and intestines were in the normal position and performed their mechanical functions normally. They also showed, however, a stone in the left kidney (Fig. 15), a condition which certainly would not have been expected from the symptoms.

The following case is another example of pain and vomiting in childhood in which a positive diagnosis would have been impossible without the assistance of the Roentgen ray, except with an exploratory laparotomy.

Case 7.—O. L., girl, aged 15½ years, was not nursed when a baby and had much disturbance of the digestion during the first three years. She had always been constipated and for many years had had frequent attacks of colic and abdominal distress. As the result of these attacks, she had been afraid to eat and her diet had become so limited that she was a semi-invalid. When 13½ years old, and again when 15, she had had very severe attacks of abdominal pain, associated with distention and vomiting, lasting for several days. A month before she was seen she came into the hands of a new physician, who found resistance and slight tenderness in the region of the appendix. These symptoms disappeared when her bowels were thoroughly moved. Three weeks later, after a light dinner, she had an attack of pain and distress in the abdomen and vomited about 2 quarts of brownish material, without marked gastric or fecal odor. She was seen a week later.

The patient was short and thin, but of fair color. Her tongue was somewhat coated. The abdomen was sunken and showed nothing whatever abnormal. She stood in normal position, not in that usually assumed when there is prolapse of the abdominal organs.

Roentgenograms, taken after a bismuth meal, showed on two occasions exactly the same points. There was marked prolapse of the stomach and small intestines, with delay in emptying the stomach. The sigmoid and the splenic flexure were in the normal position. There was marked prolapse of the cecum into the pelvis, with prolapse of the ascending colon. The ascending colon was bent sharply downward on itself for 4 or 5 inches, when it turned sharply upward into the transverse colon, which ran up to the splenic flexure in the normal position. The two parts of the ascending colon were always in the same relation to each other in all positions and at all times. The plate (Fig. 16), taken nine hours after the bismuth meal, showed the stomach empty, but a residue of bismuth in the first part of the duodenum. It also showed the cecum deep down in the pelvis. Those taken twenty-four and thirty-six hours after the meal (Figs. 17 and 18) showed the bend in the ascending colon and also showed that the position of the two parts of the ascending colon to each other is always the same.

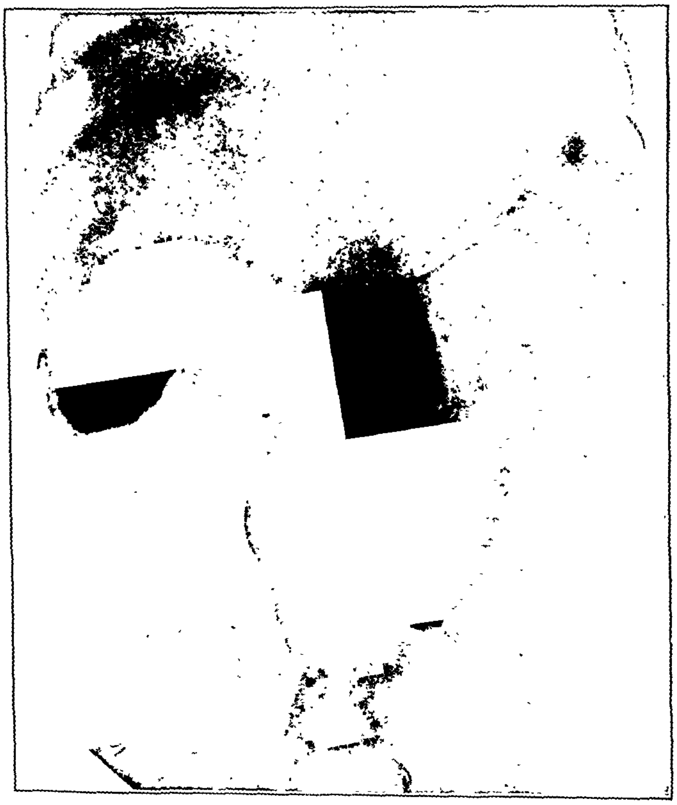

Fig. 23.—Case 9. Taken anteroposteriorly after bismuth enema.

These pictures (Figs. 16, 17 and 18) justify the diagnosis of adhesions binding down the colon and involving the duodenum, with presumably secondary prolapse of the stomach and small intestines. The constipation was probably due to the obstruction caused by the adhesions, and the attacks of vomiting to blocking. A laparotomy, two months later, revealed peritoneal adhesions in the places shown by the Roentgen ray.

Constipation is one of the most troublesome disorders of childhood and it is often difficult to determine the cause of the constipation. The Roentgen ray is of great assistance in many of these cases in determining whether or not there is any delay in the passage of the food through the gastro-enteric tract and, if so, where the delay takes place. The following instance shows how much information may be gained from the use of the Roentgen ray in these cases:

Case 8.—B. J., boy, aged 4 years, was very hard to feed as an infant, a wet-nurse finally having been necessary. He did very well, however, until he was weaned, since when he had had repeated attacks of indigestion, with vomiting. These attacks were always preceded by an increase in the constipation, which was always present. In spite of careful feeding, he required laxatives almost constantly.

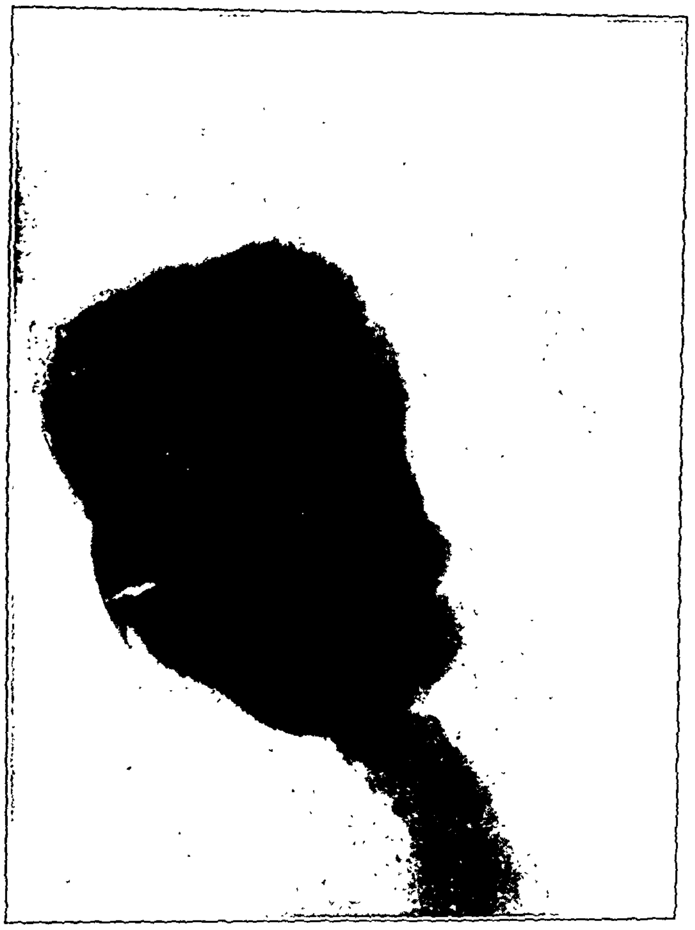

Fig. 24.—Case 9. Taken laterally after bismuth enema.

He was in fair general condition and his color was good. His tongue was clean. The abdomen was sunken and nothing abnormal was detected in it. A roentgenogram (Fig. 19), taken immediately after a bismuth meal, showed the stomach in normal position. Another (Fig. 20), taken two hours later, showed that no bismuth had left the stomach during this time. One (Fig. 21), taken six hours after the meal, showed that, while there was a residue still present in the stomach, the greater part of that which had escaped had passed into the large intestine. One (Fig. 22), taken twenty-four hours after the meal, showed the stomach and small intestines empty and almost the whole of the meal in the cecum and ascending colon, very little of it having passed farther on. The constipation was evidently due, therefore, not to sluggish peristalsis in general, but to delay in the colon, the delay in emptying the stomach probably playing no part in the etiology of the constipation.

It is often important to determine whether the colon is in front of or behind an abdominal tumor. Dilatation of the colon with air or water is of assistance in determining this point in some instances. In many others, however, the results obtained in this way are most unsatisfactory. Here, also, the Roentgen ray is often of great assistance. Roentgenograms of the abdomen after a bismuth enema show accurately the position of the large intestine.

Case 9.—These roentgenograms (Figs. 23 and 24) of the abdomen of a baby, 19 months old, with a large sarcoma of the left kidney, illustrate very well the value of this method of examination. The one taken anteroposteriorly shows the bismuth in the sigmoid and in the transverse colon. It is almost entirely squeezed out of the ascending colon and splenic flexure by the pressure of the tumor. That (Fig. 24) taken laterally shows the colon separated from the spine by the tumor.

The Roentgen ray is sometimes of great assistance in differentiating intussusception from infectious diarrhea, in both of which conditions there is blood and mucus in the stools. In some cases of intussusception the roentgenogram taken after a bismuth enema shows a cup-shaped cap of bismuth about the lower end of the intussuscipiens, while in infectious diarrhea the bismuth is generally disseminated throughout the colon. Unfortunately, however, the picture is not always so plain in intussusception, and it is impossible to be certain from the roentgenogram whether there is or is not an intussusception.

These examples are, it seems to me, sufficient to show how useful the Roentgen ray is in the diagnosis of obscure abdominal conditions in childhood and to illustrate how varied the conditions are in which it is of service. There are probably also many other conditions, which have not been mentioned in this paper, in which it will prove to be of equal value.

70 Bay State Road.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. CHAPIN AND MORSE

Dr. Abraham Jacobi, New York: Dr. Chapin referred to some conditions which have been known in former years simply from a physiologic and anatomic point of view. In connection with the two cases which he calls Hirschsprung's disease, he mentions protracted constipation, and, from his illustrations of the lower part of the colon and sigmoid, I concluded that some of these cases were undobutedly those that forty years ago were called by me congenital constipation. That means a condition of the sigmoid in which it is so long that it forms not one convolution only, but two or more, and absolute constipation is the result. When you find a baby that has been constipated from birth, a constipation lasting for months or years, with a mother who has the full amount of breast milk and who gives the baby no other food, you have reason to conclude that the case is one of congenital multiple sigmoid flexions. When the sigmoid is so long, it bends on itself, and sometimes absolute obstruction occurs. This is, however, not to be called Hirschsprung's disease, which means a congenital dilatation of the colon, the genuine megalocolon, which is a rare occurrence.

Dr. G. R. Pisek, New York: It is significant that we should have three papers dealing with this method of diagnosis in one afternoon. It proves the increasing value of the method and should emphasize the importance to all of us of the use of the Roentgen ray in pediatric work; and particularly urge us to take advantage of the newer methods that experts in this line are developing. In other words, the fact that we can take instantaneous serial pictures, without any danger whatever to the little patient, is of inestimable value, particularly in conditions dealing with pyloric spasm and pyloric stenosis. Indeed, if this were the only use, it would be worth while, for it enables us to differentiate the two conditions, tells us when to put the case into the hands of the surgeon or satisfies us that it can be treated medically.

I was glad to see Dr. Morse's pictures of gastroptosis. It has occurred to me that possibly such diseases as psychic vomiting may also be found by these methods to be of anatomic origin. Possibly we may find that a number of these related conditions are precursors of diseases of the digestive tract in later life.

Dr. L. G. Cole, New York: I should like to ask Dr. Chapin if he considers that the contraction, which he obtained in two cases after giving an enema, is the same thing that Holzknecht described as occurring when food is given by mouth and allowed to progress through the gastro-intestinal tract in the regular way, or whether he considers the contraction he has shown as a spasm from unusual filling of the colon from below.

Dr. A. W. Crane, Kalamazoo, Mich.: It is gratifying to see Roentgen-ray methods invading the realm of general practice, not excepting pediatrics. In the past children have been bad subjects for roentgenoscopy, but with instanteous exposures conditions have changed. Roentgenography will, however, fail to impress the general practitioner as a true clinical method of examination. It is the fluorescent screen which gives us true moving-picture images of the stomach and intestines, as well as of heart, lungs and diaphragm, and provides us with a direct clinical method of examining the child.

The first objection that might be suggested to you should be the danger of exposing young tissues to the Roentgen ray. This danger may be minimized by using the smallest amperage which will give a clean-cut shadow, and the slowest number of interruptions which will admit of shadows without flickering. In this way roentgenoscopy extending from five to ten minutes will be comparable in quantity of ray used to that used in instantaneous work, in which several roentgenograms are made. Dr. Cole of New York is one of the best qualified men in the United States to discuss this question of serial roentgenograms. He has recommended that no studies of the stomach be made without ten or twenty roentgenograms of the stomach in series. If we use a screen, plates are not, as a rule, needed.

Only by repeated studies on the part of many pediatricians, can the mass of knowledge necessary to interpret roentgenograms be worked out. The large number of cases that has come before the Holzknecht X-Ray Clinic in Vienna has enabled them to work out a uniform technic whereby a normal or diseased stomach under certain conditions would present certain definite pictures to the examiner. It is only by having a uniform technic that we can classify results and arrive at a collective experience of value in the examination of the stomach and intestines. It seems to me that those who have witnessed screen examinations in a dark room and have palpated the stomach and colon while they are under observation, can realize the transcendent value of this method. There is no other clinical method which offers so much for the future of diagnosis.

Dr. Henry F. Helmholz, Chicago: I should like to ask Dr. Morse about the case with the "V"-shaped transverse colon. I have noticed in post mortems on children that this condition is quite frequent. I wonder whether he has roentgenograms of a large number of cases to indicate how often this occurs.

Dr. H. Lowenburg, Philadelphia: While I agree that it is of great importance to make roentgenographic studies of these cases, it is wrong to give the impression, especially with reference to cases of pyloric obstruction, that they must necessarily be studied in that way in order to determine the diagnosis, prognosis and treatment. I was particularly interested in Dr. Morse's paper. With reference to his first series, I think the same results can be obtained by the administration of charcoal. You can test the patency of the pylorus by the administration of charcoal and whether or not it can be recovered in the feces. This depends on the degree of obstruction. If charcoal is recovered the next day in the stomach washings it indicates considerable or complete obstruction, and the possibility that the case will become surgical is made greater. Absence of charcoal in the washings lessens the possibility of operation. I think that the greatest field for Dr. Morse's work is in the second series, or in older children. The prognosis of pyloric obstruction depends entirely on the clinical features, namely, on the degree of obstruction as determined by the amount of constipation, the charcoal test, the degree of emaciation and the strength and the persistence of vomiting. If a child is passing a little feces and the body remains stationary, or there is a little gain, we have a right to watch the case. I think the weight, strength and the degree of constipation determine whether or not operation should be performed. Whether the case be one of spasm or of hypertrophy is not important, as complete or incomplete obstruction may be due to either or to both; therefore, I think that a better term than pyloric stenosis would be pyloric obstruction, partial or complete, depending on either hypertrophy or spasm, or a combination of these.

Dr. John L. Morse, Boston: Dr. Sever of Boston is making a large number of roentgenograms of children after administering bismuth in order to get the relations of the intestines. It is not at all uncommon to find a "V"-shaped colon as shown here to-day, and to have the children manifest no symptoms whatever. It does not seem to me that it is justifiable to make a diagnosis of abnormality simply from a picture. If there are symptoms which can be explained in no other way and the picture shows an abnormality, it seems to me reasonable to consider this abnormality as the cause of the symptoms. This is especially true when the putting on of an abdominal band and the giving of exercises relieves the symptoms.

Dr. L. R. DeBuys, New Orleans: There are many chemicals which will give a shadow with the Roentgen ray. I have felt, however, that since bismuth had no ill effect whatever it was safe to use it. There is no doubt that we have in the past been procrastinating too much before referring our patients to the surgeon. They have frequently been given to the surgeon after they have become poor surgical risks. Since the mortality is 50 per cent., it seems to me that we should adopt all the means possible to establish a diagnosis in order to place these cases in the hands of the surgeon earlier. After the diagnosis is made with the aid of the Roentgen ray and we are prepared to turn the case over immediately, if necessary, then we are justified in putting off operation so long as the baby is making a daily gain and improving satisfactorily, because for each day the baby lives, if he gains in weight, his resistance will become greater and he will be better able to withstand an operation.

Dr. Henry Dwight Chapin, New York: With reference to Dr. Cole's question, I consider that possibly due to peristalsis. I cannot say positively. It may have been due to spasm.

DISARTICULATION OF THE KNEE-JOINT [*]

F. J. GAENSLEN, M.D.
MILWAUKEE, WIS.

It is not often that the orthopedic surgeon is called on to amputate an extremity. Occasionally amputation may have to be resorted to as a life-saving measure, in far-advanced tuberculosis or other bone disease. The fact, therefore, that such occasions do arise, as well as the fact that the procedure to be described involves essentially orthopedic principles, are sufficient reasons for bringing up the subject before this Section.

In conditions requiring amputation through or in the neighborhood of the knee-joint the surgeon has a considerable variety of operative methods to choose from. In this choice he is influenced in the first place by the pathologic condition present which determines how much of the limb must be sacrificed regardless of other conditions, and in the second place by the desire to leave the patient as useful a stump as possible. In the latter consideration weight-bearing is probably the most important factor. The literature on the subject evidences a considerable diversity of opinion as to the relative value of disarticulating operations as compared with the transcondyloid or supracondyloid amputations. The chief objection to disarticulating operations has been urged from the esthetic side because the joint of the artificial limb occupies a lower level than the normal. In the erect position this is perhaps immaterial; but in sitting the thigh of the side operated on seems considerably longer. This objection does not seem to be a very valid one, as in the construction of the artificial limb the joints in the side bars can be raised sufficiently so that the difference in length will be reduced to a minimum; in fact, it will be reduced to the thickness of a heavy leather cap forming a socket for the stump. Figure 1, which represents a direct lateral view, shows that the difference is practically negligible. The advice, therefore, that disarticulations are better suited for the working-classes, while amputations through or above the condyles are better suited for those laying greater stress on the appearance of the limb, seems questionable.

---

[*] Read in the Section on Orthopedic Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

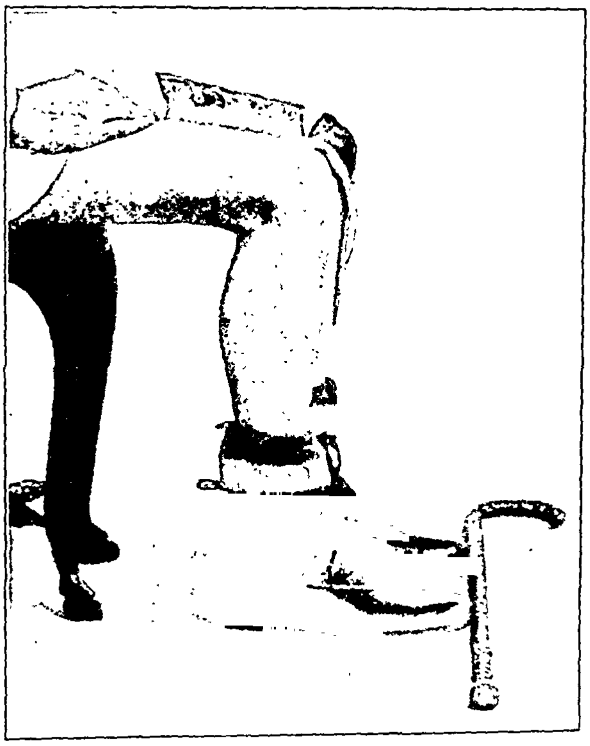

Fig. 1.—Direct lateral view with patient seated, showing slight difference in lengths of the two thighs.

The method about to be described was devised for the purpose of securing a broad weight-bearing surface utilizing the patella in addition to the condyles in contrast to methods previously described. In common with other disarticulating operations there is no necessity for carrying the artificial limb to the tuber ischii for support, as is the case in all thigh amputations.

The principal points in the technic are the preservation of the patella and the extensor apparatus by division of the patellar ligament close to the tibial tubercle; lengthening of the quadriceps tendon to allow the patella to be brought down into apposition with the lower surface of the femur, and the performing of an arthrodesis between the patella and femur in the intercondyloid space at such a point that the pressure-bearing surface of the patella will lie on a level with the condyles. In this way weight will be distributed equally between these three large, smooth surfaces, thus affording an eminently satisfactory weight-bearing surface. Furthermore, the skin covering the patella is usually more or less thickened and therefore suited for bearing pressure. The muscular balance of the limb is little interfered with.

In the brief review of the various methods of amputation in this region, mention will be made only of points which are of importance in comparison with the method already outlined.

Until Carden's transcondyloid operation became better known, it seems that a good many lower third thigh operations were performed which might with benefit have been made through the condyles. Among the advantages rightly claimed for this were that the section of the bone was below the marrow cavity, that the vascular cancellous tissue healed more quickly, and that the cut surface was broad enough to yield an adequate weight-bearing surface in the majority of cases, while the great length of the extremity insured good control of the artificial limb. Furthermore, there was much less tendency to protrusion of the bone. The objections to the method were the occasional sloughing of the flaps, whether long anterior or posterior, and occasionally, also, a tender scar closely adherent to the bone rendered weight-bearing difficult. Lister said of it at that time, "Considering, therefore, that this procedure can be substituted for amputation of the thigh in the great majority of cases, both of injury and disease formerly supposed to demand it, Carden's operation must be considered a great advance in surgery."

Gritti's operation marked a further advance in utilizing the patella as a weight-bearing surface. He sacrificed the lower portion of the condyles, making his section transcondyloid, and after shaving off the cartilaginous surface of the patella fixed it to the cut surface of the femur. An objection here was the marked disproportion in size between the section of the femur and that of the patella, the latter forming only an incomplete cover. Furthermore, there was such great tension that the patella frequently became dislodged, sliding back to its former position in front of the femur, or else became partially loosened and tilted, rendering weight-bearing painful or impossible. In other cases, when sufficient tension was made to keep it in place, necrosis from pressure sometimes resulted. In order to overcome these objections Stokes modified Gritti's method by carrying his section of the femur fully one inch above the condyles, thus making it a supracondyloid operation. This allowed the patella to be brought into position more easily, while the disproportion in size between the bone surfaces was greatly diminished. Care must be taken in employing this method to save the adductor tubercle, the integrity of the adductors being of great service in the control of the stump.

Disarticulating operations require long flaps in order to cover the large condyles, and therefore in many cases, when sufficiently long flaps are not available, the transcondyloid, or perhaps better, the supracondyloid operations, will have to be resorted to following the Stokes-Gritti method.

When one has a choice, disarticulation with lateral flaps seems to offer decided advantages over the other procedures mentioned. The advantages are the preservation of the broad condyles intact as weight-bearers, and the preservation of the semilunar cartilages with their fascial attachments, causing little disturbance of the muscular balance as well as insuring against retraction of the soft parts with consequent protrusion of the bone. This method usually goes by the name of Stephen Smith.

The procedure employed in the case to be reported differs from the latter in the lengthening of the quadriceps tendon, allowing the patella to be brought down between the condyles; arthrodesis between the patella and intercondyloid surface, and fixation of the patella in this position by the suturing *of the patellar ligament to* the hamstring tendons and capsular tissues behind. The advantages of this procedure are employment of the patella as a [illegible] ace in addition to the broad condyle [illegible] of the patella, which insures better preservation of the quadriceps apparatus, while suturing of the ligamentum patellae and hamstrings posteriorly affords firm attachments for the latter tendons and further safeguards against retraction of the soft parts which would result in thinning and fretting of the skin with consequent danger of exposure of the bone. Figures 2 and 3 show the patella in place as indicated, the lower portion of the patella being practically on a level with the lower surfaces of the condyles. These radiograms were taken about three months after operation.

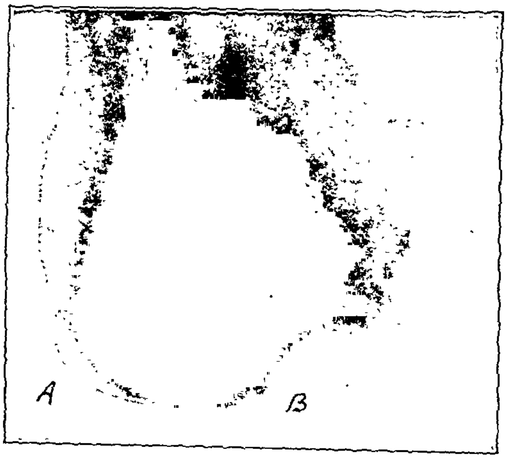

Fig. 2.—Lateral view showing patella (*a-b*) on under surface of femur between condyles.

While all of the methods outlined no doubt will find special applicability in individual cases, depending on the character and localization of the pathologic lesion as well as nutrition of the integument, my method has given a satisfactory result and can be recommended whenever existing conditions permit.

REPORT OF CASES

History.—A man aged 56, saloonkeeper, with negative family history, Pott's disease in childhood and recovered with moderate kyphosis. Sixteen years ago the tibia was trephined for supposed osteomyelitis. The wound discharged for about a year, but finally healed after a secondary operation at which several small sequestra were removed. The wound remained closed until a year and a half ago when the patient in falling bruised the scar over the shin. An acute osteomyelitis developed and continued with more or less marked constitutional symptoms which gradually undermined his health. The radiogram revealed such extensive destruction of bone that fracture seemed imminent. In view of the patient's age and general condition, disarticulation was suggested.

Operation and Result.—Feb. 18, 1913, an incision was made beginning in the middle line posteriorly above the joint line extending vertically downward, then sweeping outward in a blunt curve with the convexity downward, the lowest point being about 2.5 cm. below the tibial tubercle. The incision was then carried upward inside of the tibial tubercle and about 1 cm. inside the inner edge of the patella to 5 or 6 cm. above the upper edge of the patella. This brought the scar between the patella and the inner condyle and out of the way of pressure. A similar flap was cut on the inside, meeting the vertical portion of the first. The skin and fascia were now dissected upward a short distance. The soft structures about the joint were divided transversely and dissected with the skin and fascia to provide a thick covering for the stump. The patellar ligament was divided close to the tibial tubercle. The section through the joint was carried between the head of the tibia and the semilunar cartilages, leaving these on the femoral side. The quadriceps tendon was then lengthened by two transverse incisions about 3 cm. apart, beginning at opposite sides of the tendon and extending about two-thirds across the width of the tendon. An attempt to do this from beneath with the flap reflected upward proved unsatisfactory so that the patella and tendon were dissected partially free from the flap. The patella was now brought down in the desired position and with chisel and hammer the cartilaginous surfaces of the patella and the intercondyloid space were removed, exposing the marrow. The ligamentum patellae was sutured posteriorly to accessible portions of the hamstring tendons and posterior capsule. The closure of the wound was with silkworm gut and fine black silk, a cigarette drain being left posteriorly. A large dressing was held in place with broad adhesive straps so adjusted as to keep the thigh flexed to avoid tension. The drain was removed in three days, the wound remaining clean and the flap margin showing no sloughing. While the patient remained in bed flexion was continued with sand-bags and pillows. The patient left the hospital at the end of three weeks with the wound completely healed. He was instructed to keep up flexion for several weeks more whether recumbent or erect. The artificial limb was applied three months from the date of the operation and the patient has been able from the first to bear full weight on the stump without difficulty.

408 Goldsmith Building.

ABSTRACT OF DISCUSSION

DR. EDWIN W. RYERSON, Chicago: The chief difficulty that I can see with this particular operation was partly covered by Dr. Gaenslen in his paper; that is, that it makes a femur that is no shorter than the other and that, theoretically at least, is a little longer; so that it is difficult for the apparatus maker to construct an artificial leg that will not protrude too far when the patient is sitting. It is difficult to avoid conspicuous deformity when the patient has his trousers on. I have done several amputations at the knee-joint for various causes; and the instrument maker assured me that a shorter stump was mechanically advantageous, so far as his experience went. The recommendation to remove the adductor tubercle is wise, although it is the adductor magnus only that is fastened to it, and the other adductors furnish good power. The insertion of the quadratus into the hamstring tendons is also wise, but is usually neglected by general surgeons in this work. Otherwise, the tendons will react and a great deal of muscular power of the thigh will be lost.

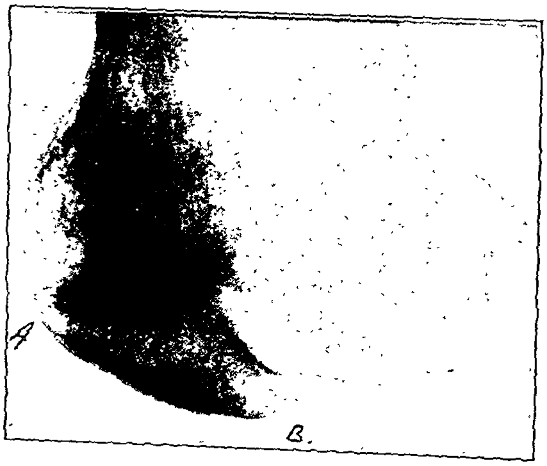

Fig. 3.—Anteroposterior view.

Dr. F. J. Gaenslen, Milwaukee, Wis.: I have nothing to add, except that, in the preparation of the artificial limb, the socket for the stump consists of a heavy sole-leather cap, which is scarcely more than a quarter of an inch in thickness. As a result there is, in sitting, only a minimal difference in length of thighs. In the present instance the increase in length was negligible.

A STUDY OF THE END-RESULTS OF THE BALDY-WEBSTER OPERATION *

JOHN OSBORN POLAK, M.D., M.Sc.
BROOKLYN

In this brief paper, which is based on a personal experience of over 400 cases, I shall attempt to draw conclusions from the end-results of the Baldy-Webster operation.

THE PRINCIPLES OF UTERINE SUPPORT

The uterus is a freely movable organ and is suspended in the pelvis between the abdominal cavity and the pelvic floor by the harmonious action of all of its supports; that is:

The pelvic floor.
The adjacent pelvic organs.
The retentive power of the abdominal cavity (*intra-abdominal pressure*).
The several ligaments.
Finally, by the normal relation which the uterine axis bears to the axis of the vagina.

The axis of the uterus with the bladder and rectum moderately full conforms with the axis of the pelvis, and is nearly at a right angle with that of the vagina. With the bladder empty, the axis of the vagina is almost horizontal and runs almost directly backward, while the uterus is directed forward at an acute angle.

Normally, the fundus of the uterus is at or a little above the level of the pelvic brim, while the inferior extremity of the uterus, the cervix, projects into the vagina and is directed toward the last sacral vertebra. With all the adjacent pelvic structures in their normal state, the cervix is more or less a fixed point, lying in the plane of the ischial spines, a little posterior to the center of the pelvis. The cervix is held in this position by the uteropelvic ligaments and the uterosacral ligaments and the vesicovaginal fascial plate; the body rests on the pubic shelf.

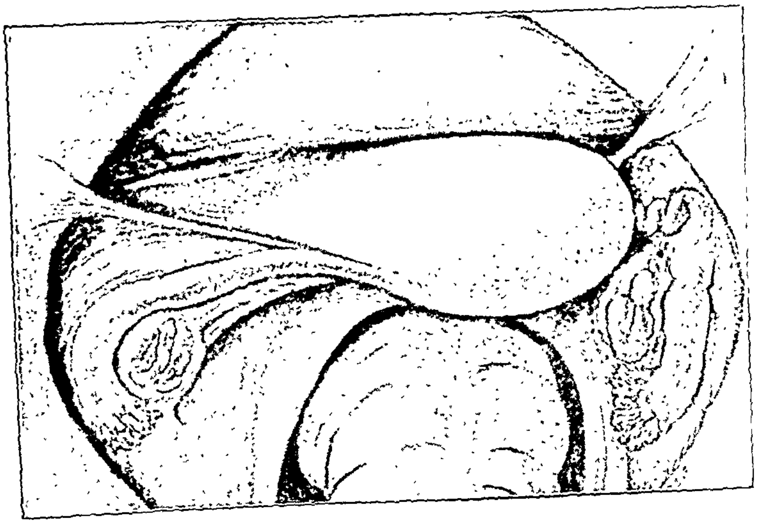

Fig. 1.—Lateral version of the uterus.

The normal axis of the uterus has a wide range of inclination, depending on the degree of fulness of the bladder and rectum; the uterus moves upward and downward with each respiratory excursion and changes its position with that of the body.

THE ACTION OF ITS SUPPORTING LIGAMENTS

The uteropelvic ligaments consist of bands of muscle fibers running outward from the supravaginal portion of the cervix to the pelvic fascia, within the base of each broad ligament; they prevent the uterus from undergoing lateral changes in position and help materially in preventing uterine prolapse. The broad ligaments act in some measure to steady the uterus in or near the median section of the pelvis. The uterosacral ligaments pull the cervix backward and upward, thus tending to antevert the body, while the round ligaments act as stays or "guy-ropes" to draw the uterus forward and prevent it from falling backward. The round ligaments are muscular bands covered with peritoneum.

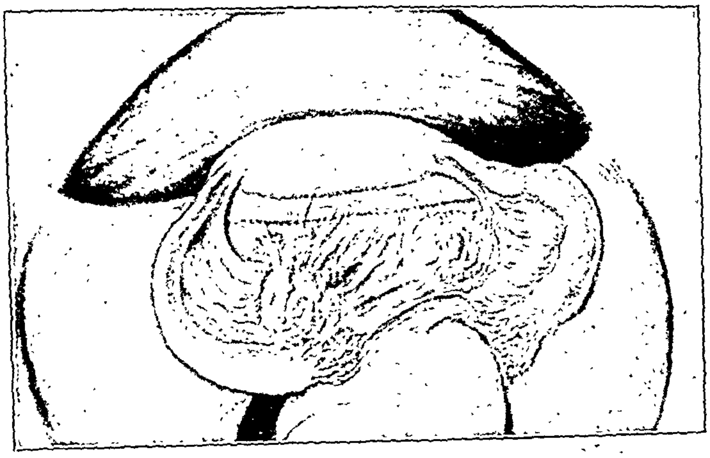

Fig. 2.—Ovaries adherent to one another and thrown upward and inward by heavy uterus slipping out of sling.

WHAT THE BALDY-WEBSTER *OPERATION* DOES

The Baldy-Webster operation elevates the uterus and its adnexa and holds the fundus forward. This is accomplished, according to Baldy, by three forces:

1. The intra-abdominal pressure on the posterior fundal wall.
2. The encircling band formed by the round ligaments.
3. The downward pull of the round ligaments on the uterine cornua.

In this operation the uterus is upehld by the encircling loop of the round ligament which is sutured to the posterior surface of the body, in a line just below the level of insertion of the utero-ovarian ligament. The ovaries and fallopian tubes rest free of broad ligament attachment on the round ligaments, as they pass through the broad and under the utero-ovarian ligaments.

The perfect correction of a retrodeviation of the uterus by this operation must therefore depend on the following conditions:

1. A cervix held backward and upward by well-developed uterosacrals.
2. A good pelvic floor to preserve the position and integrity of all of the pelvic organs.
3. A uterus of moderate size and weight, and round ligaments of equal length and thickness which can be made to encircle the uterus.

The technical difficulties of the operation are for the most part insignificant, yet they are present.

---

* Read in the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

POSSIBLE COMPLICATING DIFFICULTIES IN THE TECHNIC

Clinically, we find that the round ligaments are frequently unequally developed in length, thickness, and in muscular tone; this is commonly so post partum, when the retroversion or flexion is associated with subinvolution, descensus and pelvic injury. The use of such ligaments for the Baldy-Webster operation must necessarily produce a lateral version of the uterus, and this has been an end-result too often noted (Fig. 1).

Varicosities of the veins of the pampiniform plexus are common to all retrodisplacements with descensus. The passage of the round ligament through the opening made for it by blunt dissection in the broad ligament may injure these veins of the utero-ovarian anastomosis and give rise to troublesome bleeding, the control of which by ligature may further interfere with the venous circulation, or even produce a thrombophlebitis which may extend from the pelvis to the femoral or the saphenous vein. Thrombosis has been relatively more frequent following this operation than after other procedures on the round ligaments.

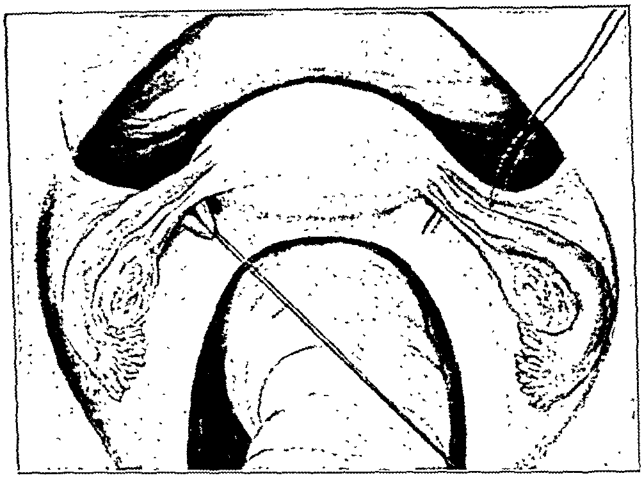

Fig. 3.—Author's technic.

Strangulation of a portion of the ligament which has been drawn behind the uterus is not uncommon, and has occasioned in several instances a local peritonitis. Congenital or acquired adhesion of the sigmoid to the posterior surface of the broad ligament may complicate the technic by relatively shortening the ligament on that side.

Unless the ligaments are fastened low enough on the posterior uterine wall, i.e., just below the level of the utero-ovarian insertion, there is a tendency for the ovaries to be carried upward and to be thrown over forward with the rolling forward of the broad ligaments; they may even be rolled into the anterior peritoneal pouch, while if the attachment is too low, the ligaments serve as a loop over which the body may bend, making a retroflexion out of a retroversion.

Torsion of the ligaments is a common error in technic, the importance of which is apparently not appreciated by many operators; this always gives rise to swelling from obstruction to the circulation of the ligament, and local peritonitis with more or less extensive local adhesions. I believe that the severe inguinal pain noted following some of these operations may be attributed to this cause.

To the critics who state that the Baldy-Webster operation puts a strain on the weakest part of the ligament, i.e., the portion nearest the inguinal canal, I would state that this operation does not claim to suspend the uterus by supporting or hanging it by the round ligaments, as does the Gilliam, but simply draws the fundus forward, and if the cervix is well back and firmly held there by the uterosacrals, intra-abdominal pressure will retain the organ in anteversion.

ITS EFFECT ON THE POSITION OF THE OVARIES

The ovaries are elevated by this operation. This is accomplished in the following manner:

1. By the general elevation and anteversion of the uterus.

2. By the rolling forward of the top of the broad ligament, owing to the pull backward of the round ligament as it passes through the hole in the broad ligament. The patency of the tubes, if free from adhesions, is not interfered with by this disposition of the round ligament.

In almost all cases of retroversion of long standing there are varicosities of the broad ligaments, and changes in the size, position and histology of the ovaries, which result in prolapse, thickened stroma and cystic degeneration, making it imperative, in order to secure a symptomatic cure, that the basic causes as well as the position be corrected, i.e., that the pelvic circulation be equalized, not obstructed. In the ideal case in which the uterus is not too heavy, the ovaries and tubes are normal and the cervix is held well back toward the sacrum by its supports; i.e., the uterosacral and the uteropelvic ligaments. Shortening the round ligaments by encircling the uterus with the loop of the round ligament meets all of the claims of its originators; but when the uterus is heavy, the round ligaments attenuated or unequally developed, and the cervix points forward, either because of congenital malformation, or as a result of the stretching of the uterosacral ligaments, the uterus will fall into lateral version or sag in the pelvis. What really takes place when the uterus sags may be illustrated by attempting to lift a small boy by placing your arms under his axillae and embracing him with your forearms. He can't get away except by sliding from your embrace by raising his arms. So the uterus slides out of the encircling band down into the pelvis, raising the ovaries and throwing them inward toward the median line, where they may become adherent to one another, behind and above the ligamentous sling (Fig. 2).

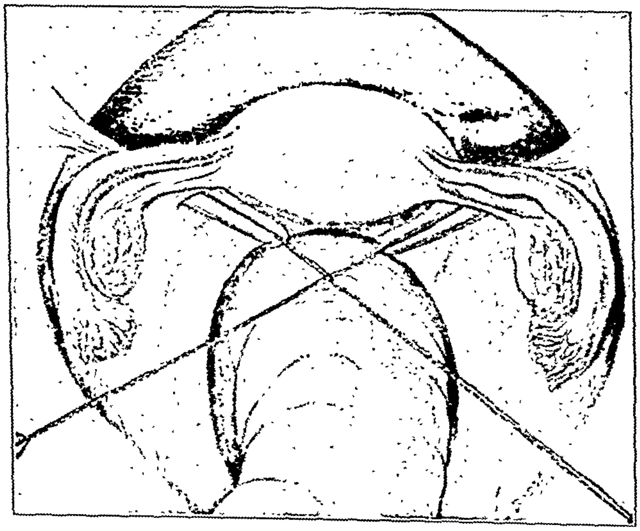

Fig. 4.—Author's technic.

Yet no operation for retroversion of the uterus seems to meet the indications so perfectly as does this one of Baldy's, when all conditions [illegible] vorable.

The technic in my clinic has been slightly varied from that described by Baldy in 1910. I have felt that grasping the ligaments with "guy-ropes" causes less trauma than catching them with clamps. Again, I have substituted a Cleveland ligature carrier for the clamp to pass through the free space below the ovarian ligament, as being less likely to injure the blood-vessels than the Kocher forceps. I have generally spread out the loop of each round ligament on the posterior surface of the uterus, fixing it at three points; i.e., in the median line to its fellow from the opposite side; to the utero-ovarian ligament at the point at which the folded ligament passes through the broad ligament, and to the uterine wall midway between these two points (Figs. 3, 4 and 5).

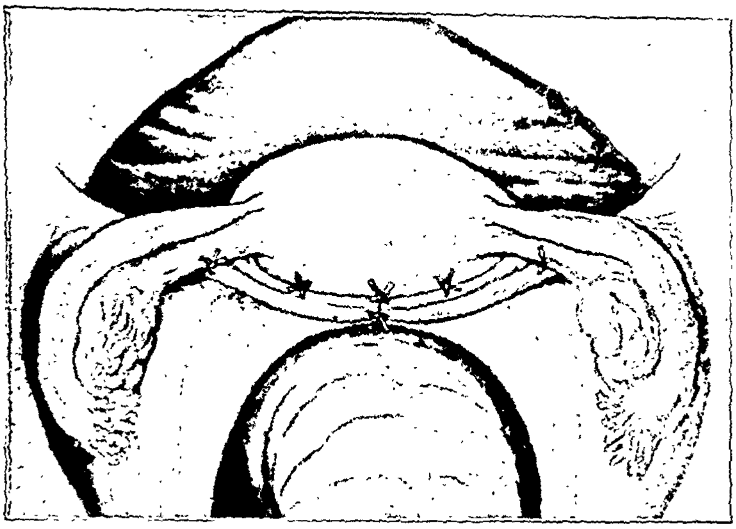

Fig. 5.—Author's technic. Sutures in place.

From a study of the records of the 400 operations in my clinic from Jan. 1, 1908, to Jan. 1, 1913, I make the following summary:

SUMMARY

Twenty-four patients have been lost track of and have not been seen by either my assistants or myself since their operation, thus leaving 376 for analysis. These women have been watched for periods varying from five months to five years and many of them have been examined repeatedly. Two hundred and two, or more than 50 per cent., have perfect pelves; the uterus is in its anatomic position in the pelvis and free from adnexal or parametrial inflammation. Of this number, 160 have had complete relief of all pelvic symptoms.

Thirty-nine having an anatomically perfect pelvis, still complain of pelvic pain, with burning sensations over the lower abdomen, and suffer from menstrual pain in the back and side.

Three have died from causes independent of the operation before or soon after leaving the hospital. It is among the remaining 174 that we find our complications and disappointments.

Fourteen have had secondary operations for pelvic or abdominal conditions, and the intra-abdominal pathologic conditions in each have been carefully studied and the findings recorded. These have shown that:

1. Unequal development of the ligaments does occur and lateral version of the uterus follows; this I believe to be due either to torsion of the ligament from defective technic, or to unequal primary development, present but unnoticed at the time of the operation.

2. Enlarged ovaries slung over the encircling band formed by the round ligaments fall lower in the pelvis by elongation of the utero-ovarian ligament and become adherent. These ovaries (Fig. 6) have been cystic (mycrocystic).

3. The sigmoid is apt to become adherent to the ligamentous loops.

4. The ligaments passed behind the uterus may become edematous from constriction and offer an inflammatory surface for intestinal adhesion.

5. When the uterus is large and sinks in the encircling loop, the ovaries are thrown upward and inward and become adherent to one another behind the uterus, forming a sensitive mass; these findings have been constant in the cases reopened; hence we would judge that some of this pathology is a cause in many unrelieved patients.

In thirty-two patients the uterus has relapsed and was found retroverted and prolapsed, carrying the ovaries with it.

Thirty are wearing pessaries.

Eighteen have not been benefited in any way.

Ten have lateral versions of the uterus and complain of pain in the side toward which the fundus is drawn.

Sixteen have prolapsed and cystic ovaries.

Two women have ovaries lying anterior to the broad ligament.

Twenty-six have had thrombosis of the pelvic veins, which has extended to the femoral and saphenous, which gives a morbidity larger than we have had from any other intra-abdominal operation.

Twenty women have had children subsequent to the operation.

Twenty-two have aborted, making in all forty-two pregnancies from which to make observations. No complication of labor has been recorded; only one delivery has required forceps.

Fourteen of the women becoming pregnant have had great pain and discomfort during the first trimester; only four of our relapses have followed labor.

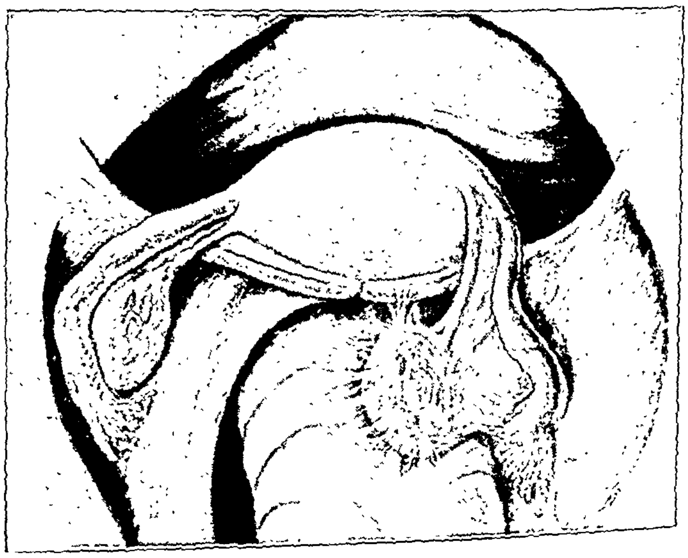

Fig. 6.—Further elongation of the utero-ovarian ligament due to enlarged ovary.

CONCLUSION

From these observations it would seem that the Baldy-Webster operation has a definite field of usefulness in properly selected cases of retrodeviation of the uterus when intra-abdominal shortening of the round ligaments is employed. It should not be selected for heavy uteri with the cervix in the axis of the vagina. Its success depends on a small uterus, a cervix pointing backward, equally developed ligaments and a careful technic.

287 Clinton Avenue.

ABSTRACT OF DISCUSSION

Dr. Edward Reynolds, Boston: The Webster-Baldy operation is, I think, the best of the round-ligament operations, but I think that there is a word more to be said. Dr. Polak has told us that the normal position of the uterus is maintained by the harmonious action of all its supports. A very important corollary is that, in the majority of cases of retroversion, the condition is due primarily to the existence of a tendency toward retroversion due to the inharmonious action caused by an unequal development of those ligaments. The uterus is an organ which is suspended, and when it retroverts it revolves about a point which is approximately the attachment of the bases of the broad ligaments where the uterine arches approach the cervix. A band formed by the anterior attachments draws the cervix forward and down, while the uterosacral muscular structures lift the cervix upward and backward. If the Webster-Baldy or any other round ligament operation is applied to a case of this kind an anteflexion of the fundus is created in addition to the anteflexion of the cervix. Dr. Somers has told us that the only expedient he can see is to shorten the uterosacral ligaments and pull the cervix upward and backward. That operation has been before the profession for many years and has not met with much favor because it is an incorrect procedure. For six years or more I have been doing an operation which I believe is a much better procedure. I make a transverse incision through the uterovaginal plate, extending through the whole thickness of the anterior vaginal wall in front of the cervix and large enough to admit a finger. I pass the finger in and separate the bladder from the anterior surface of the cervix and then break up the connective tissue and muscular tissue which we call the vesico-uterine ligaments, leaving the cervix free from all the attachments which drag it forward and downward. I then bring the incision together with transverse sutures. With the Webster-Baldy operation I bring the fundus forward, and the uterosacral ligaments lift the cervix backward.

Dr. R. S. Yarros, Chicago: I have watched the Webster-Baldy operation as done by one of its originators for several years, and I have seen more bad results from this one operation than from almost any other. In several cases I saw all the complications that Dr. Polak mentions. One of the cases, if I remember correctly, had three of the complications. It was a simple case of retroversion, with a slightly enlarged uterus and an enlarged ovary. The operation was done and part of the ovary removed. Two years afterward the woman was operated on and it was most difficult to separate the uterus from the bladder. The result was a hysterectomy. Two other patients had to be operated on within two years, not only for discomfort, but for severe pains.

I have come to the conclusion that it is a mistake to displace the anatomic relations. The Webster-Baldy operation seems to me a fundamental mistake, unless it is done as guardedly as Dr. Polak suggests. First, however, how is it possible to measure the ligaments and say that they are equal? If one is clever enough to forestall all these points no doubt the operation has a place. I am sorry that Dr. Webster is not here himself to say all the good things in favor of the method, for Dr. Polak certainly did not say many things in its favor.

Dr. C. W. Barrett, Chicago: We are indebted to Dr. Polak for so honestly reporting such unfavorable results. His results have shown the evils of the operations which were pointed out theoretically a long time ago. There has been some question for a number of years whether the operation should be called the Webster or the Baldy operation. As a matter of fact, Dr. Baldy has about as much right to have his name attached to this operation as Cook has a right to claim the discovery of the North Pole. There is no reason why the operation described by Dr. Webster should be called the Webster-Baldy operation.

It seems to me that these reports in regard to the ill-advisedness of this operation should be convincing to the most skeptical individual. An abdominal operation must be safe and simple; it must allow inspection of the contents of the abdomen; all of these requirements this operation does to a certain extent fulfil, except that of safety. Then it must use natural ligaments instead of false ligaments and must use the strongest part of the round ligament. The round ligament grows smaller and smaller toward the internal ring, and any operation that throws out the two-thirds of the anterior portion of the ligament throws out the very best part of the ligament we have for holding the uterus forward.

Dr. J. O. Polak, New York: This discussion has brought out just what I had hoped it would bring out—the results of some of the other observers. I felt that perhaps my results were due to faulty technic or a misconception of the principles of the operation, but they have been reported to you fairly. Dr. Reynolds made the point that anomalies of the uterus, such as the deep posterior invagination of the cervix, complicate retroversion work. We have found that no retroversion operation will cure patients of this class permanently, unless the cervix is placed and held backward toward the sacrum. I brought this point out some six years ago in a paper which I presented to the American Gynecological Society on the result of suspension of the uterus. It was only by the use of a pessary immediately after our suspension operations were done that we were able to present such excellent results in restoration of the uterus—results not obtained by other men with this operation. This was not because of the technic, but because we recognized that the cervix must be kept backward, and that, if this was done, the fundus would be maintained forward by intra-abdominal pressure. The pessary in a large number of cases did this mechanical act.

I am sorry that I gave the impression that I have condemned the Webster-Baldy operation. I have not. I am still using it occasionally, but am selecting the cases. These four hundred cases include all degrees of retroversion. We were doing the Webster-Baldy operation on the cases in which we removed a tube or an ovary or in which we were doing straight retroversion work. We are now selecting for this operation the small uterus with well-developed round ligaments, with few, if any, varicosities in the broad ligaments, and with a cervix that is not congenitally anteflexed.

IS MEMBRANOUS DYSMENORRHEA CAUSED BY ENDOMETRITIS *

K. I. SANES, M.D.
PITTSBURGH, PA.

In this paper I shall use the term "menstrual membrane" instead of membranous dysmenorrhea because we are interested in all the membranes passed during the menstrual period, and since not all are accompanied by pain, the term "membranous dysmenorrhea" cannot cover them all. I shall use the term "membranous dysmenorrhea" only when I wish to convey the idea of a membrane passed with pain. Before taking up the question of the relation of the menstrual membrane to endometritis, it is essential to consider the histology of the endometrium.

HISTOLOGY OF ENDOMETRIUM

The description of the endometrium as given by the anatomists is not uniform. In the old description the endometrium was considered as a definite and unchangeable structure. The picture of the endometrium most commonly met was considered to be the normal one and any deviation from it was looked on as pathologic.

---

* Read in the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

Milnes Marshall[1] and Heape,[2] independently of each other, reported a classification of the endometrial changes during the menstrual cycle and thus gave us a better understanding of the endometrial structure. They divided the cycle of twenty-eight days into four periods: The period of construction (about five days), the period of destruction (about four days), the period of regeneration (about seven days), the period of quiescence (about twelve days), and described the well-defined changes normally noticeable in the endometrium in each of these different stages. They thus widened the range of the endometrial changes within the physiologic limits and gave us a more accurate description of the endometrium. My description will be based on this classification, but for the purpose of this paper it will be sufficient to describe the endometrium during the quiescent stage and then give its changes during the construction (premenstrual) and destruction (menstrual) stages.

THE ENDOMETRIUM IN THE QUIESCENT STAGE

During the quiescent stage, the epithelial cells lining the surface of the mucosa and glands show considerable differences in their shape, size and nuclei. (The superficial epithelial cells are more cuboidal and somewhat smaller than the glandular ones).

The glands during the quiescent stage appear straight or slightly tortuous and are situated in regular and almost parallel rows. Their distance from each other is given by Winters[3] as from two to two and a half transverse diameters of a gland and by Gebhard[4] as from four to five. The size of the glandular lumen is given by Winter as from a half to one cell in width. Each gland is surrounded by a network of spindle-shaped connective-tissue elements, and outside of it by the stroma. (The same spindle-shaped cells are noticed in the neighborhood of vessels and in the deeper layers of the mucous membrane.)

The stroma during this stage appears to be a soft, somewhat mobile protoplasmic mass, imperfectly differentiated into cells. These cells anastomose freely with one another by means of protoplasmic processes closing in the small lymph cavities. They present many and varying alterations in shape, and can readily be displaced by fluid or blood (James Young[5]). At its uppermost layer the stroma cells are arranged parallel to the surface, forming a kind of basement membrane. During this stage there is no mitosis. The blood-supply of the superficial portion of the mucosa consists of capillaries running parallel to the surface epithelium without any specialized supporting coats; James Young[5] and Heape[2] consider the intima and the media of the vessels as consisting of the ordinary flattened cells, and the capillaries as simple blood-tracks through the protoplasmic mass.

THE PREMENSTRUAL OR CONSTRUCTIVE STAGE

During the constructive stage there gradually develops a pronounced serous infiltration of the upper layer of the mucosa. This infiltration or edema has been recognized by Leopold,[6] Westpholen,[7] Young,[5] Hitchman[8] and Meerdervoort.[9] It is ascribed by Young to changes in the stroma cells associated with the liberation of a crystalloidal element. "This crystalloidal element brings about an osmotic pressure discrepancy between the protoplasm of the stroma and the blood in the vessels, to readjust which an outflow of fluid takes place from the lumen of the vessels into the intima and stroma cells." As a result of this process, the intercellular spaces become saturated with the fluid transuded from the vessels, and the perinuclear protoplasm of the stroma cells becomes transformed into a number of fluid spaces bounded by the displaced and thinned-out cytoplasm. The borders of these swollen cells according to Westpholen become indistinct and their nuclei paler, rounder and more central.[7] "It is very possible," says Young,[5] "that the network of previous writers in reality corresponds to these spaces in the protoplasm enclosing the fluid actively imbibed." In addition to these changes in the stroma cells themselves, round-cell infiltration and capillary congestion constitute a characteristic feature of the stroma during this stage.

The changes in the glands are also characteristic. They assume a more tortuous appearance, they dilate often from ten to twenty times their size and their interspaces become greatly lessened. (Westpholen[7]). The epithelial lining of the glands undergoes edematous changes similar to those seen in the stroma. The cells are somewhat lower, their outline less distinct and their nuclei paler. The walls of the glands show in places clusters of epithelial cells (papillary processes). Their lumina become filled with mucus and in some places also with leukocytes and red cells. These glandular structures are found only in the deep layers of the mucosa. The superficial layer is rather poor in glands. We therefore have normally in the premenstrual stage two layers in the endometrium; the lower or spongy one, and the upper or compact one (Hitchman[8]).

THE DESTRUCTIVE STAGE OF MENSTRUATION

We see then that before the beginning of menstruation the endometrium presents an edematous stroma of almost jelly-like consistence with wide capillary tracks running through it, and that it then consists of two layers, a deep spongy one and a superficial compact one.[10] With the approach of menstruation the arterial congestion leads to the dilatation of the superficial capillary tracts, and under increased vascular pressure and the condition of the intima and stroma described before, an emigration of red cells from the capillary tract takes place. Whether it is a simple mechanical leakage or, as Young suggests, "an active dragging out of the cells" by the same force that determines the edema, is, of course, difficult at present to say. Whatever the force may be, the red cells either enter the stroma, and pushing it aside form lacunae, or they find their way through the edematous stroma into the lumina of the dilated glands. In either way, the blood can reach the uterine cavity; in the first case, through the displaceable stroma and surface epithelium, and in the second case, through the glandular openings.

A point of great importance in connection with our subject is whether any endometrial tissue is carried away with the blood. On this point there are contradictory opinions. Sir J. Williams (in 1877), von Kahlden (in 1889), Wyder (in 1887), and Wendeler, (in 1895), basing conclusions on necropsies (deaths during menstruation) found extensive denudations of the endometrium; Heape,[8] and Wyder and Gelabin,[11] examining menstrual discharges, found in them uterine epithelial cells and shreds of stroma tissue; Westpholen[7] and Lohlein, from studies of curetted material, came to the conclusion that epithelium and stroma are exfoliated to a slight extent; De Sinety, Moricke, W. Williams and Jacob[11] state that the endometrium is not denuded at all; and Gebhard, while not denying any exfoliation of stroma, admits exfoliation of epithelium. Now, contradictory as these observations appear, they meet the view of Meedervoort[9] and Mandl[12] who assert that the extent to which the mucosa is destroyed varies within wide limits in different persons and even in the same persons in different periods of life.

[10] Ruge makes the same division in his description of endometritis glandularis hypertrophica which Hitchman asserts is nothing more than the premenstrual physiologic condition of the endometrium.

MECHANICAL DENUDATION

How can the denudation be explained? What is the mechanism of the separation of endometrial tissue from a menstruating uterus? To this question different answers are given; but it is generally ascribed to the extravasation of blood in the spongy layer with a condition present in the compact layer preventing the free outflow of blood through it. The easily displaceable spongy layer offers no resistance, the blood accumulates there and by its pressure displaces and dissects the softened edematous stroma and the dilated edematous glands. The portions of endometrium thus loosened are expelled under the influence of the uterine contractions during menstruations.[13]

THE DESCRIPTION OF MENSTRUAL MEMBRANE

Menstrual membranes vary a great deal in their macroscopic and microscopic appearances. Different pieces of membrane from the same person at the same periods may present strikingly different pictures. I shall not discuss here the macroscopic appearances of the membranes, as it does not come within the scope of my subject; microscopically the membranes show signs of degeneration varying from a mildly hydropic appearance of the cells to a complete coagulation necrosis when it becomes a fibrinous membrane. Some authors do not consider the fibrinous membrane as an exfoliated endometrial membrane, but fibrinous membranes and exfoliated endometrial membranes may pass at one and the same time and a single section made of a menstrual membrane may show the pictures of both. I may therefore justly state that it is impossible to separate the two varieties anatomically, especially if we remember that there are many transitional forms between them, and I shall consider, therefore, the fibrinous casts as a form of menstrual membrane.

The fibrinous membranes consist mostly of fibrin intermingled with blood, round and polymorphonuclear cells. The membrane may be so degenerated that only by repeated examinations of sections can one find a necrotic outline of glandular and vascular structures. Occasionally, however, in these fibrinous membranes, especially at the area of its separation, endometrial tissue of definite structure may be seen.

The membranes that are not entirely necrotic present such a variety of microscopic pictures that it is hardly possible to describe them all. They may consist chiefly of stroma with glands few and far apart, or they may consist chiefly of glands with but little interglandular tissue. The cells of the stroma may be necrotic, may assume a decidua-like appearance, may be slightly edematous or even normal; they may be thickly set or widely separated by an exudate. The stroma may be studded with red cells, round polynuclear cells, and occasionally with plasma cells. Fibrin is usually found in the stroma and clasmatocytes are not rarely encountered. The glandular tissue presents no less variety in structure. The glands may be small or very much dilated; they may be straight or tortuous; their epithelium may be normal or present different degrees of degeneration; their lumina may be filled only with mucus or may show also accumulations of different cells (red, round polymorphonuclear cells). They may be found completely isolated from the stroma or may be closely surrounded by it. They may lie near and even touch each other or may be widely separated.

A feature noticed by von Franque, Hager and Meyer and described as a "budding" of the interglandular tissue is sometimes met in the membranes. It is a compact mass of stroma cells in which growth is more active and which penetrates through the loose stroma cells in different directions.

In a general way we may state that in the menstrual membrane we see the premenstrual pictures of the upper layer of the endometrium in the different degrees of its degeneration.

IS THE MEMBRANE A RESULT OF INFLAMMATION?

The present general opinion is that the cause of menstrual membrane is an endometritis (Gottschalk,[14] Leopold,[6] Grechen,[15] Wyder,[16] Morse,[17] Beigel,[18] Kleinwachter,[18] Lohlein,[11] Kustner,[19] A. Martin[20] and Kelly and Noble.[21] But why ascribe the exfoliation of the membrane to the inflammation of the endometrium? Does any one assert that the menstrual membrane is a symptom of endometritis? Is there any clinical and histologic evidence to prove it?

Clinically, there are no intermenstrual symptoms characteristic of passing menstrual membranes, nor are the symptoms of endometritis necessarily present in such cases. Kollman[22] found no such symptoms in twenty-four membranous cases that he examined. On the other hand, membranous dysmenorrhea is not infrequently hereditary (Sireday, Beigel, Tilt, Brouardel, Duplan and Huchard.) and is occasionally associated with the passage of membranes from other organs such as the vagina (Huchar, J. Williams, Guyenot,[22] Hogan[23] and Leopold[6]), and rectum (Cohnstein,[24] Gauthier and Bordier[22]), and even with skin desquamation. Such clinical facts do not speak in favor of the dependence of membranous dysmenorrhea on endometritis.

[13] Kollman (Schein, S. A., Zur Anatomy der Endometritis exfoliativa menstrualis nebst Klinischen Anhang, Arch. f. Gynäk., 1906, lxxx) goes a little further. He asserts that the extravasated blood in the deep layer deposits between the separated endometrium and the uterine wall a fibrin which, together with a leukocyte infiltration, gives rise to a membrane analogous to sequestrum formation.

[24] Cohnstein: Ueber vaginitis exfoliativa und dysm. membranacea, Arch. f. Gynäk., Berlin, 1881, vol. xvii.

Nor are there any histologic proofs for such a dependence. Of sixty-two cases of menstrual membranes collected by Cohnstein,[24] forty-two cases, or 68 per cent., showed no disease of the sexual organs. Thomas, Mayer, Scanzoni and Solowieff[22] reported cases of membranous dysmenorrhea without evidences of diseased sexual organs. Schaeffer[25] did not find endometritis in the mucosa obtained during the intermenstrual period in such cases. Even Leopold, who is in favor of the inflammatory etiology of the menstrual membranes and approves of the name "endometritis exfoliativa," says,[6] "It is worthy of note that the membranes described as exfoliative endometritis when examined are found to be normal."

Of course there is no reason why an endometritic uterus could not expel a menstrual membrane. There is no reason why *intermenstrual curettage of a patient* passing menstrual membranes could not show an endometritis, but this does not prove that an endometritis causes the menstrual membranes, for as H. Meyer[26] justly states, "even if the mucous membrane is found to in a state of chronic inflammation, its findings do not vays agree with those of the expelled menstrual memrane."

But does not the menstrual membrane itself present an inflammatory picture? Of course it does; but this picture is found normally in the endometrium at the end of its premenstrual stage. The edema of interglandular stroma, the dilated vessels, the exudate, the round-cell infiltration, the dilatation and proliferation of glands may be and has been considered features of inflammatory processes (an endometritis), but such hanges must be considered physiologic in the premenstrual period and, therefore, cannot be considered inflammatory in the menstrual membrane. For if the picture of menstrual membrane could prove an endometritis, then all menstruating uteri have endometritis.

MENSTRUAL MEMBRANES IN MONKEYS

In this connection it is important to call attention to the description of the endometrial changes during the four stages of the menstrual cycle in monkeys—*Semnopithecus entellus* and *Macacus rhesus* as given by M. A. Heape,[2] and *Cercocebus cynomolgus,* as given by Van Herwerden.[27] Space will not permit me to quote their description; suffice it to say that it is similar to that of the endometrial changes in the human female. In the monkeys the degenerative stage is always accompanied by the passage of a menstrual membrane. "The uterine epithelium," says Heape, "and the superficial stroma shrivel up and exhibit signs of degeneration, the epithelium ruptures and the blood contained in the lacunae is poured into the uterine cavity. Denudation follows. All the uterine epithelium, a portion of the glands and in some places whole glands and a depth of about one-third of stroma are cast away with the ruptured vessels, red corpuscles and leukocytes. Of these substances, the menstrual clot is formed." A menstrual membrane then always accompanies the menstruation of monkeys. Are we then to attribute this menstrual membrane in monkeys to an inflammation? Have all the monkeys endometritis? If the passage of the menstrual membrane in monkeys must be admitted to be physiologic, why must we consider it in the human female as dependent on endometritis? Is it because it is rare in the human female? But is it rare?

THE FREQUENCY OF MENSTRUAL MEMBRANE

The passage of membranous tissue is a great deal commoner than it is usually supposed. While MacNaughton Jones,[28] Grechen,[15] Stevens,[29] Lockhart[30] and many others consider it a rare form of dysmenorrhea, John Williams, Scazoni, Oscar Frankl,[31] von Franque, E. G. Herman,[32] Norris[33] and others consider it of very frequent occurrence. If we were in the habit of carefully examining the clots for shreds our idea of the frequency of menstrual membranes would be different. It should be remembered that membranes are most frequently passed as clots; that it is difficult to separate them from clots, and that in case of fibrinous membranes, they are often overlooked even on microscopic examinations. Again, the passage of membranes is not always accompanied by pain, and therefore more membranes are passed than membranous dysmenorrhea would indicate. Within the last three months, I saw and had sectioned in my practice six menstrual membranes.

DYSMENORRHEA WITH THE MENSTRUAL MEMBRANES

Because of the fact that clinically we have opportunities to observe only patients in whom the passage of menstrual membranes is accompanied by severe pain, we become accustomed to the association of the idea of menstrual membranes with that of dysmenorrhea (membranous dysmenorrhea). Now, dysmenorrhea, in general, is common in our women, and if the menstrual membranes are as common as we believe them to be, there can be no reason why dysmenorrhea should not accompany the passage of membrane in a percentage of cases. But the dysmenorrhea accompanying the passage of membrane in such cases may be dependent on conditions other than the passage of membrane itself. C. E. Herman asserts that it is never caused by the membrane *per se.* Patients, like the one of Gibbon's,[35] who sought his advice because the complete uterine cast was larger than the ones painlessly passed by her monthly before, confirm Herman's view. If we can, as we justly believe we can, dissociate the dysmenorrhea from the passage of menstrual membrane, we take away a great deal of its pathologic aspect.

IS STERILITY COMMON?

But how about sterility? Is it not commonly met among women passing menstrual membranes? And if it is, does it not suggest the pathologic origin of the menstrual membrane? We surely cannot call normal a condition which interferes with the functions of an organ. To answer this question we must again bear in mind the frequency with which menstrual membranes are encountered. Not only is the great army of women that pass menstrual clots with or without pain fertile, but even in the bad cases commonly recognized as cases of membranous dysmenorrhea, the women are not absolutely sterile. Solowieff, Fordyce Barnes, Thomas,[36] Lohlein,[18] von Franque, Schaeffer, Kleinwachter, Championon, Henwig and Bordier reported pregnancies in

women suffering from membranous dysmenorrhea. Fritsch goes so far as to say that membranous dysmenorrhea not only does not cause sterility but does not even favor abortion. While the percentage of sterility may be high, if only the bad cases of membranous dysmenorrhea that come to the physician's notice are taken into consideration, it would unquestionably be found to be low if we could include in our statistics all the patients who pass menstrual membranes. It should not be forgotten that among the sterile women that we treat, only a small percentage gives a history of expelling menstrual membranes.

From all that has been said before, I feel justified in concluding that the menstrual membrane is commonly encountered, that it is not the result of an inflammatory condition of the endometrium, and that taking its frequency into consideration it is not accompanied by a high percentage of pelvic pathology and sterility.

OVARIAN HORMONES

What causes the difference in size and extent of the exfoliation of the endometrium? May it not depend on the degree of intensity of the active agent of menstruation and possibly also on the degree of sensitiveness of the endometrium to the agent? Our knowledge on this subject is far from complete. It is generally admitted that the stimulus for menstruation is ovarian in origin. Up to date, the part of the ovary which produces this stimulus is not known. The corpus luteum, the connective tissue and, lately, the parovarium (Bucura[37]) have been suggested as the active part in ovarian internal secretion.

The work of Krauer, Halban, Pfleiger, Morris and others suggested the view that as a result of the periodic function of the ovary, a substance is produced which, when carried through the circulation, induces the uterine changes necessary for menstruation and pregnancy. According to A. L. McIlroy[38] and K. I. Korovitsky,[39] these biochemical substances are hormones secreted by the ovaries and carried by the blood to the endometrium, where it sets up by its irritation, such changes as congestion, cell proliferation, edema and even tissue necrosis. It is possible that the degree of intensity of this hormone decides the intensity of the menstrual process; that is, the more active the hormone and the more susceptible the endometrium the more extensive and the more destructive are the uterine changes. If, then, supposing that the hormones are insufficient to call forth in the uterine stroma the necessary amount of crystalloid material for induction of the edema, might not the superficial layer remain insufficiently edematous to allow the blood to break through it? On the other hand, if the hormones are excessive or the mucosa too sensitive to them might they not induce destructive changes in the cells calling out fibrin formation or coagulation necrosis? In either case the blood cannot pass through the hardened mucosa and, accumulating in the spongy layer, may cause exfoliation of part or the whole of the upper compact layer.

May it not, therefore, be that the normal menstruation, with the slight superficial shedding of epithelium and the exfoliation of endometrial shreds or membranes, are the results of the same normal process, the difference being due to the variable degree of intensiveness of the stimulant action of the hormones?

Jenkin's Building.

ABSTRACT OF DISCUSSION

DR. ROBERT T. FRANK, New York: The main question concerning membranous dysmenorrhea centers on the pathology, because the treatment is largely dependent on that. If it is an inflammatory condition, we must treat it accordingly. If purely an exaggerated physiologic function, we are probably more powerless than in the other case. I agree more or less with Dr. Sanes in the view that in some instances it is congenital. So far as treatment is concerned, in such instances we are powerless, although lately I have seen one case in which the nasal treatment has been followed by the disappearance of the dysmenorrheic membrane. How the cauterization of the nasal membrane acts on the membranous dysmenorrhea I do not know, and we are no nearer solving the question of the cause of the condition.

DR. HENRY O. MARCY, Boston: I am surprised that the great work of Prof. G. B. Ercolarri of Bologna, Italy, on "The Reproductive Processes in Man and Animals," has not been referred to. This I translated; the last edition in 1884. The utricula glands of the uterus perform a special normal function. Menstruation is putting the house in order for the little tenant, who may never arrive. The woman would not be reproductive were it not for the changes that go on in the shedding to the very base of the utricular glands. This new endometrium is the most important factor in reproduction. In endometritis we have the most favorable condition for bacterial development and pathology of the reproductive organs.

DR. G. GELLHORN, St. Louis: On microscopic examination, the casts of membranous dysmenorrhea hardly ever show inflammatory changes. For this reason, curettage, as a rule, is of no avail, and the condition is, indeed, usually incurable by the ordinary means. My studies of syphilis of the uterus make me feel that a certain percentage, at least, of cases of membranous dysmenorrhea is due to tertiary syphilis. I believe that in all such cases a trial with mercury and potassium iodid should be made before resorting to curettage.

DR. K. I. SANES, Pittsburgh, Pa.: Hysteria is given by most of the authorities as the most important etiologic factor. Of the six cases of membranous dysmenorrhea that came under my observation, five were hysterical. Syphilis and tuberculosis are mentioned as causes by a great many authors. Inflammation is frequently given as a cause of membranous dysmenorrhea, because the picture of glandular endometritis is found in the premenstrual uterine mucosa in patients with membranous dysmenorrhea. I do not know how much reliance is to be placed on Hitchman's statement, but, after extensive study of endometritis, he came to the conclusion that so-called glandular endometritis is a normal condition of the uterine mucosa in the premenstrual stage. In patients curetted a few days before menstruation, we obtained this glandular structure. In this connection it may be interesting to note that in a case of membranous dysmenorrhea in which we curetted two days before menstruation the scrapings showed stroma and the glands completely degenerated thus resembling the fibrinous membrane the patient had been passing monthly.

The Irrepressible Antivaccinationist.—With the antivaccination faddist and fanatic the case is altogether different. He is a crank on vaccination simply because he did not happen to become a crank on Christian Science or something equally preposterous. On the occurrence of small-pox in a town he immediately begins his campaign of misrepresentation. He endeavors to stir up disquiet and alarm by long columns in the press on the alleged dangers of vaccination. Forgetting that the health officer is a public servant, paid to carry out the law irrespective of his personal convictions or inclinations, Mr. Antivaccinationist scarcely ever forgets to make his attack on vaccination degenerate into personalities against that official. Such attacks are at times not only contemptible, but insulting. Occasionally these pseudoscientists flood the mailbags and molest the front doors of respectable citizens with printed matter as truthful and reliable as the advertisements of Peruna or Wizard Oil.—James Roberts, M. D. in *Pub. Health Jour.*

RADIUM IN INTERNAL MEDICINE

ITS PHYSIOLOGIC AND PHARMACOLOGIC EFFECTS [*]

L. G. ROWNTREE, M.D.
AND
W. A. BAETJER, M.D.
BALTIMORE

Considerable has already been learned concerning the effects exerted by radium in its many forms on various physiologic and pathologic processes and conditions. Sufficient data, however, are not at hand to make this chapter in any way complete. Much more evidence is necessary before the findings of certain investigators can be considered properly established, while in other directions entire spheres of its influence are probably overlooked in our at present early acquaintance with radium and its activity. The briefest outline of the theories, facts and data as they appear in the literature relating to radium in internal medicine are here presented.

Uric Acid Metabolism.—Gudzent asserts that the lactim form of monosodium urate (the form present in gout) is converted *in vitro* by radium into the more soluble tautomeric or isomeric lactam form which in turn is broken up into ammonia and carbon dioxid. Neither Lazarus nor Wiechowski was able to substantiate his, Lazarus holding that Gudzent's results were depen-t on *infection of his solution with fungi (Schimmel ze).*

The consensus of opinion is that the use of radium is attended with an increased urinary uric acid output and that disappearance of deposits (tophi or artificial deposits) is hastened. Uric acid disappears from the blood under radium treatment and appropriate diet, and its disappearance is frequently associated with subjective improvement. Grave doubt still exists, however, as to the mechanism whereby the undoubted therapeutic results in gout are accomplished.

Vasomotor Changes.—Loewy and Plesch have shown that the majority of patients treated in the emanatorium show a decrease in maximal blood-pressure which may be as great as from 20 to 25 mm. Hg. Decrease in minimal and mean pressures are usually associated, and the heart work is decreased. The decreased blood-pressure is ascribed, however, primarily to vascular changes. The sleep-inducing influence of emanatorium treatment first described by Furstenberg, is ascribed by Loewy to cerebral vasomotor changes.

Effect on Blood-Pictures.—A temporary fall in the number of red cells was encountered by Noorden and Falta, but an outspoken increase which may last over weeks is described by Zehner and Brill.

A temporary but considerable leukocytosis occurs after the first sitting in the emanatorium, the mononuclears being relatively increased, while long-continued treatment leads to leukopenia. In acute febrile diseases associated with leukocytosis, an increase in the white cells is sometimes encountered, but a decrease is more frequent. In leukemia long-continued use of radium has failed to decrease materially the number of white cells.

General Metabolism.—The work of Silbergleit and of Kikoji, using the Zuntz-Geppert apparatus, indicates that radium has a definite and outspoken effect in increasing the volume of air breathed, the oxygen consumed and carbon dioxid expired, and in raising the respiratory quotient, and hence that it increases total metabolism. Loewy and Plesch failed to find these results, but they worked on only one case.

Blood Coagulation.—Von de Veldon asserts that radium emanation administered in any way exerts a definite accelerating influence on the coagulation of blood. Hoffmann corroborates this.

Effect of Radium on Ferment Activity.—It is asserted that an activating influence is exerted on pepsin (Bergell and Beckel), on pancreatin (Braunstein and Bergell), on rennin (Richet), on autolytic ferments (Neuberg, Wohlgemuth, Lowenthal and Edelstein) and on tyrosinase (Wilcox). An almost constant accelerating influence on diastase was noted by Lowenthal and Wohlgemuth. Occasionally, however, a retarding influence was encountered at first.

The evidence of definite activation in all instances is not convincing, and an investigation of its influence on lipase, now being carried out by Marshall and Rowntree, shows no appreciable acceleration.

Other Influences of Minor Importance.—Sweating frequently occurs at the time of the emanatorium treatment and continues throughout the *following night (Noorden and Falta).* The agglutinins to *Bacillus typhosus* and *B. cholerae Asiaticae* were increased, according to Schutze, in animals injected with radium water, in from five to six hours after vaccination. No hemolyzing influence has been described.

Absorption and Excretion of Radium.—Radium emanation administered by inhalation is rapidly carried to all parts of the body and rapidly reaches the concentration in the blood that it has in the air of the emanatorium. It is rapidly excreted by way of the lungs, Kemen finding none in the blood fifteen minutes after the cessation of treatment. Given by mouth it is quickly absorbed by the mucous membrane of the gastrointestinal tract, passed into the blood, distributed to all parts of the body and is excreted rapidly (in from two and one-half to three hours) by the lungs chiefly, only traces escaping in the urine.

The soluble salts of radium are rapidly excreted (four hours), no matter how administered. Injected subcutaneously, they escape (from 60 to 70 per cent.) through the intestines, smaller amounts (10 per cent.) appearing in the urine. The insoluble salts of radium pass through the intestinal canal, not being absorbed at all. Injected they remain at the seat of injection and give off small amounts of radio-activity constantly, the feces becoming radio-active.

METHODS OF ADMINISTRATION AND DOSAGE OF RADIUM EMANATION

As the Bath.—This is the original method since patients for centuries have been "taking the baths" at spas and watering-places. The degree of radio-activity varies in different spas, in the Joachim Valley 600 Mache units, at Carlsbad 90, and at Wiesbaden 10 Mache units per liter, and these all produce results. It is doubtful whether or not radium emanation can penetrate the skin—the good effects are usually considered to result from the inhalation of radium emanation as it constantly escapes from the surface of the water.

As Injection.—Emanation water containing from 500 to 1,000 Mache units to the cubic centimeter is utilized in Noorden's clinic, being injected subcutaneously or intramuscularly in the neighborhood of an involved joint once or twice a week for from ten to twelve injections. No injurious local effects result. This is usually used in conjunction with either the drink cure or emanatorium sittings, and is a valuable addition to treatment.

---

[*] Read in the Section on *Pharmacology* and Therapeutics of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

[*] A more detailed account of radium, its effects and its value, will be found in separate articles by the authors of this paper in an early number of the Johns Hopkins Hospital Bulletin.

[*] From the Pharmacological Laboratory, Johns Hopkins University, and the Chemical Division of the Medical Clinic, Johns Hopkins Hospital.

As Local Applications—Compresses, Fango Baths.—Lowenthal and Gudzent do not believe that radium emanation can pass through the skin, while Lazarus and Engelmann believe that it can. All admit that the beta and gamma rays of its decomposition products can penetrate the skin. Cotton compresses soaked in radioactive water (from 15,000 to 30,000 Mache units) are commonly used. The fango bath or *Umschlag* is an example of this form of treatment since fango is now known to be radio-active. Local applications should be used in conjunction with general treatment.

As a Drink Cure.—Radium emanation in solution is administered by mouth by varying and increasing doses (330, 1,000, 2,500, 5,000, 10,000 Mache units), repeated three times a day. Lazarus has introduced a sipping cure in which small amounts of radium emanation are drunk many times during the day, thus keeping a certain amount of the emanation constantly present in the body. This method is well adapted for general use.

As Inhalations.—This is the best but also the most expensive method of administration. An emanatorium is used—an air-tight room or cabinet in which the patients are confined and into which radium emanation is introduced, the size depending on the number of patients to be treated (six patients require from 25 to 30 cubic meters of air). The emanatorium is so equipped that the air is kept cool, and the excess of moisture and carbon dioxid removed. The desired number of patients are treated for two hours each day and the treatment repeated every day for weeks or months. The concentration of radium emanation in the contained air varies from 2 to 4 (His) to from 20 to 600 Mache units (average 22) per liter (Noorden). Masks have been introduced in an attempt to do away with the expensive emanatorium.

Reactions in the Course of Treatment.—Often during the first week or two of treatment, sometimes even after the first treatment, an outspoken increase in the subjective and objective manifestations of the disease occurs. This reaction lasts only from a day or two to a week and does not necessitate cessation of treatment. Reduction of dosage, however, may be advisable at times. Its occurrence early in the treatment of rheumatism is a good omen, since these cases usually do better than those not exhibiting the phenomenon. It is occasionally seen also in the treatment of gout but does not carry the same significance here.

Contra-Indications.—Certain authors have warned against the use of radium salts under certain conditions, hemorrhagic diathesis and purpura (Benczur), gastric ulcer (Eichholz), pregnancy (Eichholz), marked neuroses, especially when the vegetative system is involved Norden and Falta), advanced tuberculosis (?) and polycythemia (?). Nephritis was at first considered a contra-indication but cannot now be so considered (Gudzent, Furstenberg).

Indications.—The value of radium is unquestionably established in chronic and subacute arthritis of all kinds (luetic and tuberculous excepted), acute, subacute and chronic joint and muscular rheumatism (so-called), in gout, sciatica, neuralgia, polyneuritis, lumbago and the lancinating pain of tabes. In certain other conditions it is said to be of some value, although more data are necessary before this can be accepted—chronic bronchitis, chronic pharyngitis, pneumonia, myocarditis, arteriosclerosis, vasomotor disturbances, Raynaud's disease, scleroderma, idiopathic enlargement of the lymph-nodes and in chronic constipation.

CLINICAL RESULTS OBTAINED

An effort is here made to classify and bring together the results of all of the cases reported up to August, 1912. In many instances these figures are taken from tables submitted by individual authors, while in others the number of cases together with attempt to estimate the value of the treatment was made from case reports.

Chronic Arthritis and Chronic Rheumatism.—The methods of classifying these cases were so different with different authors that it was considered advisable not to attempt classification but to bring them together under this heading. All grades of severity are included. Great variation as to dosage and methods of administration and duration of treatment existed. No attempt to differentiate these cases is made but it may be stated that, as a rule, the earlier the treatment was begun and the less severe the anatomic changes, the more outspoken was the improvement.

The results in 471 cases as described by twenty-three authors are shown in Table 1. Some improvement was found in 371 cases (78.7 per cent.).

In certain instances arthritis deformans and muscular rheumatism were considered separately, and these are brought together in separate tables and are not considered in Table 1.

TABLE 1.—RESULTS OF RADIUM TREATMENT IN 471 CASES OF CHRONIC RHEUMATISM OR CHRONIC POLYARTHRITIS

Arthritis Deformans.—The results in twenty-four cases (Table 2) reported by seven authors show improvement in sixteen. Objective as well as subjective betterment was noted at times.

Muscular Rheumatism.—Acute, subacute and chronic conditions are considered in Table 3. Twenty-seven of forty-nine cases treated by ten authors showed improvement. Many of these cases of chronic arthritis had failed to respond to previous treatment by other methods. The treatment was continuous in some instances over periods of months.

Gout.—According to Gudzent and Brugsch gout is not always easy of recognition. Clinically a study of the uric acid content of the blood should always be made. In health, following five or six days of purin-free diet the blood no longer contains uric acid, whereas in gout the uric acid does not disappear as demonstrated by Gudzent and Apolant's test. Certain cases clinically called chronic arthritis show the same phenomenon, and according to Brugsch are gouty cases though not ordinarily diagnosed as such. Under radium treatment the blood of gouty patients on a purin-poor diet as a rule rapidly becomes free from uric acid. The symptomatic condition improves in association with decrease in blood uric acid according to Gudzent, but is independent of it according to Mendel.

* In thirty-seven uric acid disappeared from blood.

In 106 cases by twelve authors eighty-six patients (81 per cent.) are reported as improved, markedly improved or cured. Some of His' patients have been free from symptoms for as long as one year following the last treatment. Joint uric acid deposits and tophi are said to disappear under treatment.

Neuralgia, Sciatica, Lumbago, Neuritis and Polyneuritis.—A large series of cases falling into this group are found in the literature, some clearly, others very poorly, defined. An effort has been made to group them.

Neuralgia, including tic douloureux (Table 5): Of fifty-nine cases treated by fourteen authors forty-seven were improved, and twenty-five practically cured. Tic douloureux usually resisted treatment.

Lumbago: Five cases are reported by as many authors, considerable benefit occurring in all but one instance.

Polyneuritis: Six cases were treated and benefited by Noorden and Falta and one each by Benczur and Kemen. Sommer and Nagelschmidt saw benefit, each in one case of neuritis, but Strassburger saw none in his three cases.

To recapitulate, 152 cases or 79 per cent. of the 192 cases coming under this heading were benefited by radium treatment.

Tabes Dorsalis.—The lancinating pains were relieved in a large proportion of cases, only temporarily (weeks) in most instances, but over longer periods in some cases. Table 7 shows forty-four cases from six sources in which the pain was alleviated in twenty-six.

Gudzent, His, Furstenberg, Sommer and Klemperer speak in glowing terms of its value. The introduction of emanatoriums in a large number of the German spas as well as the establishment of a radium institute in Berlin for the treatment of medical cases express confidence in it on the part of the profession abroad.

It should be emphasized that the foregoing statements are based entirely on the results published by various foreign observers and not on the cases treated by us. Our experience has as yet been confined to too small a series of cases to permit of any special deductions. Furthermore, the cases treated have all been of a most unfavorable nature, since we have not felt that the results as published in the literature justified the exclusive use of radium therapy except in those cases which had been given the benefit of all other forms of treatment without improvement.

We must state frankly that the results in our small series of cases comprising only eighteen patients have not been gratifying. The brevity of this paper does not justify us in taking the space necessary for a detailed report of the individual cases; but briefly summarized, our results have been as follows: Our patients were treated entirely by the drinking method with water activated with radium emanation. They were under observation for periods varying from two weeks to three months and were given daily doses of from one-half to forty microcuries. Our series included the following diseases:

Five cases of arthritis deformans of the infectious type. (Of these three showed a diminution of pain and stiffness which for about one month was quite marked. Later the symptoms returned though not with the same severity as before.)

Five cases of muscular rheumatism and neuralgia, conforming somewhat to the group of polyneuralgias of von Noorden and Falta. (One of these patients was apparently cured; another was temporarily benefited, while the others were not affected.)

Three cases of tabes in which there was no recognizable change in the frequency or severity of the lightning pains. (It should be added that these patients were treated over a period of only two weeks and with doses which never exceeded two microcuries.)

One case of acute rheumatic fever (without benefit).

One case of sciatica (without benefit).

One case of Parkinson's disease (with temporary but definite lessening of the stiffness).

One case of chronic nephritis and high blood-pressure (with a lasting diminution of the pressure from over 200 mm. to about 180 mm.; with marked improvement in the subjective symptoms).

One case of gout in which the treatment was followed by a severe exacerbation in all of the affected joints.

The most favorable results have been in the cases of arthritis deformans of the *infectious* type in which three out of the five patients showed some slight but definite improvement.

We make no attempt to draw any conclusions as to the efficacy of this form of therapy from our small number of cases, but feel that any form of medication which has yielded the results reported by the European writers should be the subject of a much more exhaustive test, until its real value can be definitely established and its limitations rationally outlined.

It is with great pleasure that we take this opportunity to thank Dr. Hugh H. Young for the radium used in this work, and also Drs. Howard A. Kelly and Curtis F. Burnam for their kindness in allowing us the use of apparatus which we have as yet been unable to procure.

ABSTRACT OF DISCUSSION

Dr. R. Robinson, Danielson, Conn.: I have had but little experience in the use of radium, but a good deal of experience in its effect on my own wife. She was the subject of arthritis deformans and after being on crutches for nearly a year was practically cured by the use of radium and the hot electric-light bath, the electric-light bath being followed by the radium treatment. She drank the radium three times a day in solution and inhaled it once a day, combined with oxygen gas. The result was somewhat marvelous—one joint, which had been absolutely immovable for weeks, was easily movable as usual after the radium treatment. One knee which compelled her to be on crutches for six months and incapacitated for more than a year is practically so well cured that she is with me in the city and traveling anywhere from one to three miles with perfect ease.

Dr. William H. Mercur, Pittsburgh: Those interested in radium therapy might possibly like to know something of the excellent clinical experimental work now being carried on in Pittsburgh by Dr. William H. Cameron. This work is being done under the auspices of a company whose business it is to extract radium on a very large scale. So far he has treated over one hundred and twenty-five cases. The cases treated are largely joint cases.

Dr. Charles Stewart, Salt Lake City, Utah: For those whose pocketbooks do not allow them to buy radium I would call attention to pitchblende. An old mining man in the mountains of Colorado whom I know and who is very familiar with Denver told me that he picked up a nugget and put it in his pocket; he forgot it for a time and it burnt him. The nugget had radium in it and for a time the burn refused all the efforts of the local men to make it heal. That attracted my attention to the fact that pitchblende that does produce a burn might do some good. I have had cases which were benefited by the use of these pitchblendes.

Dr. W. H. Witt, Nashville, Tenn.: The chief value of this paper is not that it encourages or discourages the use of radium in internal diseases, but that it represents an honest and painstaking effort at clinics in which they have all resources for working out the question as to whether or not it really does any good. I believe the main interest to us in this report is that the work has been done where we know good work is done and where we can be really guided by the results they get.

RUPTURE OF A MEDIASTINAL LYMPH-NODE INTO THE BRONCHUS *

A. L. GOODMAN, M.D.
Visiting Physician to the A. Jacobi Department for Children, German Hospital
NEW YORK

History.—G. S., aged 5, was admitted from the German Hospital Dispensary to the A. Jacobi Department for Children, Nov. 25, 1912, with a diagnosis of pus in the urine. The child had been in remarkably good health; the birth was normal; the baby was breast-fed for two years. Until the present illness life was uneventful; the child had no acute or chronic illness, no coughing or expectoration, and no gastro-intestinal complaint. No tuberculosis is present in the family of the father or mother. The mother had no miscarriages. The two living children are in perfect health. Four months before, the mother noticed mucus in the urine, and the child complained that urination was painful. He cried when urinating, but there was no increased pain at the end of urination; neither was there increased frequency. A few weeks before the mother noted a slight trace of blood in the urine.

Physical Examination.—The patient is a well-nourished little boy; pupils are equal and react to light; no swelling under the eyes. The cervical, axillary and inguinal lymph-nodes are normal. The tonsils are hypertrophied; the throat otherwise is negative. The heart percusses within normal limits; the sounds are clear; no murmurs are heard. Percussion and breathing-sounds show the lungs to be in normal condition. There is no tenderness over the suprapubic region, over the region of the kidneys or over other parts of the abdomen. Percussion of the liver shows that it extends nearly to the costal border; the edge is not felt. The percussion note over the spleen is normal. There is no tenderness of the region of the kidneys; neither kidney can be felt. Both testicles have descended and are normal. The extremities are in normal condition; knee-jerks are present; there is no edema.

Laboratory Reports.—The urinalysis showed a faint trace of albumin. The urine was yellow and turbid, with a white mucoid sediment. The centrifuge specimen showed few blood-cells, many leukocytes, and few triple phosphates; no tubercle bacilli were found, but the culture showed a growth of colon bacilli.

Examination of the blood showed conditions normal. Cystoscopy revealed ulceration on the right side, near the trigon. Trabeculae were seen in several places over the bladder wall; the meatus of the right ureter was enlarged and reddened; the urine from the ureter seemed to be clear. Dr. Rehling, who did the cystoscopy, thought that the ulcerations were not of a tuberculous nature, and no definite diagnosis was made. Roentgenoscopy of the genito-urinary tract on both sides did not reveal the presence of nephrolithiasis or other abnormality.

Treatment and Course.—Treatment consisted of regulating the diet and giving small doses of hexamethylenamin (urotropin) three times daily. With rest in bed, the urine became clearer from day to day and the boy was apparently doing well. On the night of December 5, eleven days after his admission to the hospital, he was put to sleep with the other children in the ward after having partaken of the usual evening meal, feeling perfectly well and in good spirits. About 11 o'clock at night the nurse, on going from bed to bed, noticed that the child was somewhat blue and was breathing heavily, and, on trying to arouse him, found that he was unconscious. She at once notified the house surgeon, who came to the bedside finding the child with flushed face, dilated pupils and rapid breathing. It was first thought that the child was suffering from some drug poison, possibly belladonna. I was summoned to the hospital and found the child cyanotic, pupils dilated, head thrown back, arms drawn up, legs spastic, big toes dorsally flexed, and knee-jerks exaggerated. Drug intoxication was excluded.

The stomach was lavaged; small flakes of food particles were returned, and lavage was continued until the water returned clear. The bowels were thoroughly irrigated; a lumbar puncture was made, and the fluid returned under slight pressure. A tentative diagnosis of tuberculous meningitis was made; the head was elevated, an ice-bag was applied, and the child was given 2½ grains of calomel. I returned home and the house staff went to bed. About three hours later the house surgeon was again summoned hurriedly to the bedside of the boy and found him apparently in collapse and lifeless. The face was almost black. Artificial respiration was resorted to but with no result. Intubation was then performed, which was also without result. Then a tracheotomy was done, but the child did not respond on the introduction of the tracheotomy tube. A catheter was introduced through the tracheotomy tube into the trachea, but without effect. Then the insufflation apparatus was connected with the end of the catheter and, when the catheter was moved back and forth, suddenly from half an ounce to an ounce of a thick cheesy mass exuded from the tracheotomy tube, between it and the catheter. On the expulsion of this thick mass the child began to breathe more freely, the lips reddened and the cyanosis disappeared. Although the general appearance of the child was greatly improved, he remained unconscious for four or five hours longer, when consciousness gradually returned.

During the next twenty-four hours his condition remained about the same, except that he occasionally dropped into a stupor-sleep. During the first day after the tracheotomy he vomited twice, the vomitus consisting of some undigested and unchewed Lima beans which he had eaten the day before and which were too large to have been removed by the lavage the night previous. The temperature during his entire stay in the hospital and for the first day after the tracheotomy remained perfectly normal. The pulse-rate was also within normal limits.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

The day following—that is to say, twenty-six hours after the tracheotomy—the child developed an inspiration pneumonia, which ran its regular course. In the excitement of saving the child's life, the pus or cheesy mass which was forced out of the trachea was lost, with the exception of a small quantity which remained on the dressing, a culture of which showed a growth of streptococci.

The third day, with the exception of the bronchopneumonia, the child's condition was very good. The knee-jerks were present and were not exaggerated; the Babinski reflex was negative; the Oppenheim reflex was not obtained. Kernig's sign was practically within normal limits. There were no paralyses.

December 9 the eyes were examined by Dr. Denig and a slight indication of choked disk was observed. The ears were examined and found negative. The laboratory report of the spinal fluid showed a negative result from the globulin, albumin and Fehling tests. The cell-count showed 8 cells per cubic centimeter. No tubercle bacilli were found, and the guinea-pigs which were injected with spinal fluid have never showed any symptom of tuberculosis. The blood-count made the first day after the tracheotomy showed white blood-cells, 21,800; polynuclears, 70 per cent.; lymphocytes, 21 per cent.; small mononuclear lymphocytes, 9 per cent.; the blood-culture was sterile. The stools were lumpy and yellow, showing few curds. No parasites were found.

Since the possibility was realized that a rupture of an abscess or lymph-node into the trachea might have caused the symptoms, the child was sent, December 6, one day after the tracheotomy, to the Roentgen-ray department for roentgenoscopy. The report was as follows: "A somewhat widened shadow at the base of the heart. This is most marked on the left side of the spinal column and may indicate some involvement of the mediastinal lymph-nodes. On the left side, at the root, is seen a small amount of consolidation. On the right side of the spinal column, just above the shadow of the right heart, is seen protruding a circular faint shadow; this is most marked in the fourth intercostal space, and behind and above it in the third interspace is also another faint circular shadow. These usually indicate enlargement of the mediastinal lymph-nodes, and associated with a clinical history of a bladder condition I feel certain that we are dealing with a broken-down lymph-node which either has ruptured into the bronchus or was producing asphyxia by constricting the trachea, and the slight deviation of the trachea to the right just above the bifurcation rather points to this condition. If this is so, then the end of the tracheotomy tube or, rather, the catheter, probably ruptured the broken-down lymph-node abscess-cavity."

In a review of the literature in search of similar cases, the first that came to my notice was the one reported by Dr. H. D. Chapin[1] as a case of sudden death from pressure on the pneumogastric nerve, with necropsy. This was a patient in the outpatient department who was brought in for a slight cough. The only abnormal finding in the examination of the child was a slight difference of breathing on inspiration, as if there was a narrowing of some canal in the respiratory tract. During a number of weeks while the child was under observation, repeated examinations showed no change in its physical condition. One day the mother came to Dr. Chapin and reported that the child had died the night previous. At 6 o'clock on the evening of that day the child ate a hearty supper, was in good spirits, and was laughing and playing when at 8 o'clock it was seized with a paroxysm of coughing, dyspnea with marked cyanosis, and sudden death. The necropsy revealed enlarged mediastinal lymph-nodes with a ruptured abscess-cavity pressing on an inflamed pneumogastric nerve.

F. Petersen,[2] reported a case of obstruction of the trachea through a caseated and softened bronchial lymph-node, cured by means of tracheotomy. The patient was a girl aged 6, on whom tracheotomy was performed on account of severe dyspnea, with facial cyanosis and unconsciousness. Respiration was not much improved by the tracheotomy, but the correct diagnosis became apparent when small amounts of cheesy débris were found on a catheter which had been introduced into the trachea and when numerous large and small particles were forced out by the coughing until a large caseated and calcified piece of lymph-node was expectorated. Respiration then became free, and the child was discharged well one month later. No tubercle bacilli were discovered on examination of the material.

F. Nachod[3] reported a case of bronchial stenosis due to rupture of peribronchial lymph-nodes into the air-passages of a boy aged 6½. The diagnosis of obstruction of the right bronchus had been made before the performance of the tracheotomy, which served to give exit to large pieces of cheesy lymph-node from the right bronchus. The patient recovered after diffuse bronchitis and right-side pleurisy. Microscopic examination of the eliminated masses showed them to consist of lymph-nodes almost entirely caseated. The examination for tubercle bacilli had a negative outcome.

E. Gerber[4] observed a case of asphyxiation due to rupture of the caseated lymph-node into the trachea. At the necropsy a caseated lymph-node was found to have blocked the main bronchus. Tuberculous peribronchitis was demonstrated in addition to the perforation. The patient was a boy, aged 6, who was suddenly attacked with asphyxia and was dead before he reached the hospital. Death was due to the perforation of the anterior wall of the trachea, and to the passage through the opening of a piece of cheesy lymph-node which blocked the air-passage. The left lung was free, but several tuberculous foci were found in the right upper lobe. Gerber assumes that the condition causing death developed insidiously by the cheesy lymph-node first infecting and then disintegrating the tracheal wall.

V. Gandiani[5] reported a case of rupture of a caseated lymph-node abscess into the trachea. The patient was a child aged 3, who three days prior to admission became ill with cough, fever and respiratory disturbances. The pharynx was reddened, and the tonsils presented small isolated necrotic foci. The general condition was bad. Diphtheritic serum was administered. The child had a sudden attack of dyspnea with rapidly progressive cyanosis and symptoms of asphyxiation. Tracheotomy was performed, but the child died half an hour later. At the necropsy the trachea was found to be surrounded by a large packet of lymph-nodes as far as the beginning of the bronchi. The anterior wall, a few centimeters above the bifurcation, presented an orifice the size of a lentil. Through the perforation in the trachea a fairly large cavity was reached, which was emptied by pressure from outside, and contained tough, cheesy masses, which also blocked the bronchi. The peribronchial lymph-nodes were tuberculous.

Loehrer[6] reported the case of a boy, aged 4, who suddenly died under the signs of acute asphyxiation without having been ill in any way. At the necropsy a grayish-yellow structure of rather firm consistence was found which solidly packed the lumen of the trachea, filling it almost up to the bifurcation. The right bronchus, moreover, contained an opening 8 mm. in width through which a cavity about the size of a walnut, with rigid walls, was reached. This cavity was filled with pasty, friable masses. Animal experimentation showed that the changes of the lymph-nodes were due to tuberculous caseation. Loehrer points out that the softening of the caseated tuberculous lymph-nodes of the neck and the bronchi, and especially their rupture into adjacent hollow organs, are probably the result of a mixed infection.

Biedert and Fischl[7] speak of lymph-nodes without tubercle bacilli or other evidences of tuberculosis, and state that this is probably a very rare occurrence.

Skala[8] reports the case of a girl of 14, on whom a tracheotomy was performed on account of rapidly progressive dyspnea. Opposite to the tracheotomy wound in the membranous posterior wall of the trachea was a constricting abscess, the pus of which contained streptococci. The etiology of the abscess—whether due to a foreign body or originating from the adjacent lymph-nodes—was doubtful. The operation was followed by prompt recovery.

C. Comba[9] observed an unusual complication of tuberculous peribronchial lymph-nodes in a child. The boy, aged 11, had a dry cough, swelling on left side of neck, and dyspnea. On his admission to the hospital, bronchial breathing and crepitation were heard on the left side of the thorax. Three weeks later the patient died under symptoms of tuberculous meningitis. At the necropsy numerous swollen lymph-nodes were found in the anterior and posterior mediastinum. The bronchus presented an ulceration. Evidently a large lymph-node had been pressed against it by the mass of mediastinal lymph-nodes, with the result that the bronchial wall had been perforated. A fragment of caseated gland had then penetrated into the bronchus and entered into the trachea, causing severe attacks of dyspnea.

Rabot and Di Villiers[10] observed a boy who had attacks of paroxysmal coughing which resembled whooping-cough. Under progressive aggravation of the condition the patient died at the end of two weeks. The necropsy showed numerous lymph-nodes along the trachea at its bifurcation and around the large bronchi. The right lung contained a cavity. Several punctiform tubercles were also found at the base of the lung. Microscopic examination confirmed the diagnosis.

Knoepfelmacher[11] demonstrated an anatomic specimen in the case of a child, aged 2½, who had been under treatment eight days for diphtheria. Tracheotomy had been performed for sudden extreme dyspnea. The trachea was found to be free, but the dyspnea and pulmonary emphysema persisted. The necropsy confirmed the suspicion that the right main bronchus had been blocked by a tuberculous lymph-node.

Sternberg[12] reported before the Brünn Medical Society the case of a child, aged 2, who died suddenly after the rupture of a caseated mediastinal lymph-node into the trachea. The point of rupture was at the bifurcation. The trachea contained an oval piece of a caseated lymph-node about 2 cm. in length.

C. Ebert[13] reports three cases of rupture of mediastinal lymph-nodes into the trachea, with necropsies. In only one of these cases was the tubercle bacilli demonstrated.

E. Dina[14] contributes an observation on perforation of the air-passages by caseated bronchial lymph-nodes. The patient was a child, aged 5, who was admitted to the clinic with severe asphyxiation. The condition suggested laryngeal diphtheria, for which intubation was performed. Respiration still remained difficult and did not become normal until a yellowish-white mass was expelled in a coughing-fit from the tracheotomy wound. On examination, this body was found to be a caseated lymph-node in which tubercle bacilli could be demonstrated.

Coakley[15] reported a death through suffocation due to pressure of a tuberculous mediastinal lymph-node on the trachea. The patient was a girl, aged 3. Necropsy showed an oval mass, 2.5 mm. in length, lying underneath the tracheal mucosa and entirely blocking the lumen. A tuberculous focus was found in the left pulmonary apex, and also tuberculous peritoneal lymph-nodes. D. Bryson Delavan also observed a similar case.

Maillet[16] pointed out that certain symptoms in the form of acute functional disturbances may suddenly appear in the course of tracheobronchial adenopathy and may actually represent the first manifestations of a previously unrecognized or latent adenopathy. These symptoms may be of a grave, or at least alarming, character. They may be divided according to their involvement of the respiratory, circulatory or digestive apparatus. The respiratory symptoms are the most common and also the best known. Two illustratives cases are given—one, in a girl who had had a severe coughing fit with extreme dyspnea; the other in a boy, aged 2, who suffered within a week from two attacks of dyspnea, with cyanosis of the face. These attacks of acute respiratory tracheobronchial adenopathy must be differentiated from the attacks of dyspnea due to hypertrophy of the thymus.

Oeri[17] reported a case of rupture of a bronchial lymph-node into the bronchus, with a favorable outcome.

Ubert[18] reported a case of tracheal stenosis from a caseated, calcified and softened bronchial lymph-node. The patient was saved.

H. Grenert[19] gave a short review of this form of tracheobronchial adenopathy.

Betke[20] reported a case of bronchotracheal stenosis due to tuberculous lymph-nodes at the bifurcation in a woman, aged 29, who was cured by surgical interference (longitudinal mediastinotomy, according to Sauerbruch and Schumacher).

From roentgenoscopy of the chest of all children admitted to the A. Jacobi Department for Children, I am convinced that the existence of enlarged mediastinal lymph-nodes is more frequent than one has been led to suppose. Without roentgenoscopy it is, in the great majority of cases, absolutely impossible to make a diagnosis of their existence by either auscultation or percussion. It may be true that a great many persons with enlarged mediastinal lymph-nodes grow to adolescence and adult life without showing symptoms of the condition, but it seems to me that when their existence has been demonstrated this condition should be borne in mind and the child treated accordingly. From a review of the cases just cited, it is evident that the onset is usually very sudden; often, as in the case which I have presented, in an otherwise apparently healthy child. The symptoms may be divided into those showing involvement of the respiratory, the circulatory or the digestive apparatus, or a combination of all three. Those of the respiratory type show either slight respiratory sounds in auscultation, slight cough, or more marked labored breathing. The cases of the circulatory type show more or less cyanosis, accompanied with a slight respiratory cough or none at all. The digestive type starts in with fever, vomiting followed by difficult breathing, cyanosis, unconsciousness and sometimes death. These functional symptoms are varied—sometimes pronounced and sometimes practically absent. In quite a few instances when the digestive type of symptoms is presented there is also marked meningeal irritation, as in the one which I have given, and from the symptoms which the child presents it is impossible to differentiate between this form of meningismus and a true meningitis. The more I see of these cases the more I am impressed with the fact that a great many of the cases of so-called gastro-intestinal disturbance with meningeal symptoms are often cases of mediastinitis with local suppuration and absorption, rather than true intestinal toxemia. It is evident from the frequency of these enlarged mediastinal lymph-nodes that they no doubt stand the brunt of the battle of bacillary pulmonary invasion.

As regards the etiology, one must divide these cases into those of tuberculous and non-tuberculous infections. The non-tuberculous infections may be subdivided into the true streptococcus or the true staphylococcus, or a mixed infection of the two.

In the case which I have reported, repeated examinations to demonstrate the existence of the tubercle bacillus has been unsuccessful. I have the boy back again in the hospital and have injected guinea-pigs with catheterized urine obtained from the patient's ureters, and up to the present writing the guinea-pigs have shown no evidence of tuberculosis.

The necropsies in all the cases show about the same findings. The enlarged and suppurating lymph-node or lymph-nodes either press forward and partially obstruct or totally occlude the bronchus and trachea, or they press backward on the pneumogastric nerve, thoracic duct or some vessel situated in the immediate vicinity of the mediastinum. In fact, I have seen cases at necropsy in the hospital in which the mediastinal lymph-nodes have perforated into the adjacent parenchyma of the lung and formed a localized abscess which produced absolutely no symptoms *intra vitam* and was discovered only at the necropsy.

As to differential diagnosis, these cases must be distinguished from: (1) the true type of meningitis in all its forms; (2) from cases of suspicious cough or pressure on the main branches of the air-passages when the usual causes of such conditions can be excluded, and (3) from the so-called intestinal toxemias of childhood of the mild form, or of the graver form accompanied with meningeal irritation, high fever and cyanosis.

The prognosis depends entirely on whether the lymph-nodes remain in a simple enlarged state without producing any pressure on the adjacent organs, whether they go on to suppuration and subsequent perforation, or a combination of all three conditions, the most favorable course being, in case of suppuration as indicated by the many cases reported, perforation into one or other of the larger main branches of the upper air-passages and expulsion either by fits of coughing or by prompt surgical interference, as in the case cited.

The treatment of these cases resolves itself into medical and surgical. The medical treatment, as soon as the diagnosis is made, should consist in the same precautions as are indicated in other forms of incipient tuberculosis. These cases in which the lymph-nodes are hidden in the mediastinum do not differ from those cases of tuberculosis of the lymph-nodes of the neck which can be seen and which require constant attention. The child should sleep in a well-ventilated room, and should be given plenty of pasteurized milk and a good wholesome diet suited to its age, with the continuous administration—not for weeks or months, but for years—of small doses of guaiacol and arsenic. Of course, when these cases call for surgical interference, this should be promptly rendered. With the improved method of mediastinal surgery by the aid of the Sauerbruch chamber or the Meltzer-Auer apparatus, it will remain a question for future obesrvation whether or not, in cases showing symptoms of slight, moderate or more severe forms of mediastinal obstruction, it is advisable to open the mediastinum by a median mediastinotomy and remove the lymph-nodes.

I wish to thank Dr. Sanford, the house surgeon, who by his prompt and persistent measures and surgical skill in the case which I have reported undoubtedly saved the life of the child. Under other conditions the patient would certainly have succumbed. I also want to thank the other members of the house staff for their untiring assistance in this case.

136 West Eighty-Seventh Street.

ABSTRACT OF DISCUSSION

DR. WILLY MEYER, New York: I am sorry that I came too late to hear Dr. Goodman's paper. No doubt Dr. Goodman has mentioned how all these symptoms were worse in the course of the night, and how the house surgeon in the case of emergency was called on to try to save the young patient, and how, owing to his prompt action, the child's life was saved. No doubt at the time it was the proper procedure to open the trachea and to see how imminent suffocation could be averted. Certainly as to saving life it is a unique case. We do not often hear of similar cases. In the adult, however, I believe that these cases are not rare. I know that Dr. Goodman has carefully gone over the literature and collected a number of cases. I should like to report briefly one case we had not long ago under the supervision of the hospital. A young surgeon, stepping from behind a truck, walked in front of an automobile and was thrown to the ground. She was apparently not seriously injured, but an ambulance was called and she was taken to one of the nearest hospitals. On the way to the hospital the patient commenced coughing pus, and continued coughing pus, developing symptoms of lobular pneumonia, and with these conditions was transferred to our hospital with a diagnosis of some thoracic trouble, probably, on account of the expectoration of pus, tuberculosis. Expectoration of pus finally ceased, and she left the hospital after a certain time cured. We had roentgenograms made, which were of tremendous help in diagnosis. It was shown that there was peribronchial infiltration, and to all appearances—since she had had symptoms of tuberculosis before—there can be no doubt that she had a coalescence of one or more peribronchial lymph-nodes, which on account of the accident had perforated into the bronchial tract. I am sure that such cases are not rare. The patient was fortunate in that she had to expectorate the mass of pus, whereas in the interesting case brought out by Dr. Goodman there was no convenient exit for this filling up of the smaller bronchi, and if no relief had been given the child would have died.

I believe that physicians should pay more attention to these conditions, and especially insist on stereopticon examinations, which are of tremendous help in thoracic conditions.

Dr. Isaac A. Abt, Chicago: I agree with the previous speaker that this condition is not rare. It is true that Dr. Goodman himself is not positive as to the exact nature of this abscess cavity, but we have been much enlightened, especially as to tuberculosis infection, by the Vienna school, for the large number of cases examined. These reports mention almost constantly that the entrance of the tubercle bacilli is for the most part respiratory. It enters, usually, through the lung, some area in the lung constituting the initial or primary focus or lesion, similar to the initial lesion of syphilis, and soon after this there is infection of the bronchial lymph-nodes. This infection of the bronchial lymph-nodes undergoes various courses. It may form a central hyperplasia, it may remain latent or it may break into blood-vessels or lymphatics or the digestive tissues. The important thing is that, if we accept these views, the infection of the bronchial glands are of extremely common occurrence. Dr. Goodman's case with its brilliant treatment and unusual recovery is noteworthy, and the doctor is to be congratulated on the successful issue of the case.

Dr. A. W. Myers, Milwaukee: The paper which Dr. Goodman has presented did not mention the great help that the bronchoscope offers in these cases. It seems to me that this instrument is worth while bearing in mind in connection with the Roentgen-ray examinations, because they supplement each other so satisfactorily. A good many enlargements of bronchial lymph-nodes will, of course, occur in which no lesion can be seen with the bronchoscope, yet in many cases it is possible to obtain definite information through this means. It seems to me that the results are second only to the revelations of roentgenoscopy in aiding in diagnosing the condition.

Dr. C. F. Wahrer, Fort Madison, Iowa: Dr. Goodman says that the cases are to be divided into tuberculous and non-tuberculous. I should like to ask if they are not usually tuberculous. If not, what are they? It is well to designate distinctly all we know about this. I should like to know whether or not any but tuberculous infection is found in the mediastinum.

Dr. A. L. Goodman, New York: I agree with Dr. Abt in what he said in reference to tuberculous infection of the mediastinal lymph-nodes. I think that we all agree that, in the majority of cases, the tubercle bacillus is the exciting cause. There are cases, however, like the one which I had the privilege of presenting to you, on which we worked nearly eight months to demonstrate the existence of the tubercle bacillus, and we have failed in every instance. As I stated in my paper, we divided those cases—and from a study of the literature we are justified in doing so—into those which are tuberculous and those which are non-tuberculous. In the non-tuberculous cases, as in the one we had at the hospital, we demonstrated the presence of streptococci. You can have streptococcus or staphylococcus in any form, or a mixture of the two, and usually in the examination of a glandular exudate in which the tubercle bacillus is not demonstrated, we have a mixed infection.

The Roentgen ray shows the existence of the bronchial lymph-nodes distinctly. In these cases there is usually not much time to be lost, and to use a bronchoscope is not always easy.

There is one other point that I thought Dr. Meyer would bring out; that is, the possibility in the future, when we see large masses of lymph-nodes present by the aid of the Roentgen ray and other examinations, of determining whether or not surgical intervention would be indicated.

A New Tuberculosis Nostrum.—"Nurchisna" is the name of a new alleged cure for tuberculosis. The advertisement states that its inventor, a "modest gentleman," worked indefatigably for ten years making experiments on pigs, mice, sheep and himself, before perfecting the cure. The next experiment will be on the goat, which is always the public.—*Buffalo Sanitary Bulletin.*

ROSEOLA INFANTUM *

JOHN ZAHORSKY, M.D.

ST. LOUIS

The name "roseola infantilis" had an important place in the medical terminology of writers on skin diseases fifty years ago. Willan distinguished several varieties, and subsequent writers followed his classification with some variations. The older works on pediatrics had descriptions of the disease, but it is obvious from these descriptions that many different eruptions were confused under this heading as Hardaway[1] pointed out. On the advice of the dermatologists the name was dropped and recent text-books on pediatrics do not mention this affection.

For many years I have been interested in a symptom-complex, a febrile erythema, which occurs almost exclusively in infants and which deserves a place outside of the erythema group of skin diseases. To this the older writers gave the name "roseola infantilis," but did not differentiate this disease from rubella and toxic erythemata. In 1909 I discussed this subject before the St. Louis Pediatric society and referred to fifteen cases which were seen in private practice.[2] I wish to repeat some of the remarks made previously and to report twenty-nine additional cases (Cases 4 to 33).

The patient is almost always a child under 3 years of age who suddenly becomes ill with a high fever. The physician is called and on an examination of the patient finds nothing to account for the fever. The fever continues, but no diagnosis can be made on the second, third or even fourth day. Then the temperature drops to normal or nearly so and the child, who has been drowsy and irritable, sits up and commences to play. Coincident with the decline in the temperature a morbilliform rash appears on the face and neck and rapidly spreads over the body. The eruption disappears in twenty-four to forty-eight hours. There are no complications nor sequelae. No desquamation follows the disappearance of the rash.

SYMPTOMATOLOGY

These are striking and characteristic symptoms: A prodromal fever lasts from two to five days, the disappearance of the general symptoms follows the appearance of the rash and the eruption is morbilliform in character. The following brief analysis of the symptoms was given in the previous paper.

Fever.—This is generally high, ranging from 102 to 105. The usual temperature at the physician's visit is about 103. The elevation in temperature is continuous with moderate morning remissions. It is accompanied by extreme restlessness at night and drowsiness during the day. The fever falls by crisis within a few hours after the appearance of the eruption. In one or two cases the fever disappeared a few hours before the eruption was observed. In some cases the eruption covered about one-half of the body.

The Eruption.—This is distinctly morbilliform, that is, a rose-red macular, or maculopapular eruption, showing circular or elliptical lesions varying in diameter from 1 to 3 mm., with healthy skin intervening. The rash is most marked on the trunk, less so on the face. The back, buttocks and thighs are generally well covered. The lesions may occasionally be very sparse and limited to the trunk. There is no crescentic arrangement as in rubeola, and the lesions are generally not raised much above the skin.

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

[1] Hardaway: Keating's Cyclopedia of the Diseases of Children, iv, 17.

[2] Pediatrics, January, 1910.

The Respiratory Tract.—There are no catarrhal symptoms except congestion of the fauces. Sometimes the disease at the onset may be mistaken for a grippal angina. A macular enanthem was sometimes seen on the palate on the day preceding and coincident with the eruption. Koplik's spots were absent. Slight redness of the conjunctiva was observed a few times.

The Gastro-Enteric Tract.—Vomiting was noted in a few cases. Diarrhea was present a few times. Several of the little patients showed some signs of indigestion, but nothing characteristic.

Desquamation.—None was observed.

The Lymph-Nodes.—The superficial lymph-nodes in the neck were very slightly enlarged in most cases. The axillary and inguinal nodes seemed normal.

ETIOLOGY

All of my cases occurred in infants under 2½ years of age. Sex seems to exert no influence. All but one of the patients were fed on artificial food, or were given supplemental feeding to breast-milk.

The disease is not contagious. Only in one family did more than one case occur. These were two little boys, aged 2½ and 1½ years, who had the eruption three days apart. Older children who have not had rubella remained with the little patients continually without contracting the disease. The comparative isolation of these young children renders the assumption of a contagion almost impossible.

The active cause of the disease is unknown. That it is due to an intestinal intoxication is possible, but there is not much in my series to support this view.

DIFFERENTIAL DIAGNOSIS

There is only one exanthem which need be seriously considered in diagnosis and that is German measles (rubella). Measles, scarlet fever, Duke's disease, and erythema infectiosum have distinctive characters not possessed by roseola which are sufficient to separate them positively from the latter disease. So many writers have attempted to separate certain clinical types of rubella from the disease proper that one who will make another attempt is almost subject to ridicule. It is probably true that rubella is a name applied to a group of closely related infections; but roseola has such distinct features that I must insist that it deserves a separate place in our nosology. A parallelism between the two diseases clearly shows the distinction.

In rubella the prodromal fever is but of a few hours duration. The fever rises with the eruption. Children of all ages are susceptible. It is contagious, it occurs mostly in the spring and there is enlargement of the lymph-nodes.

In roseola the prodromal fever lasts three to five days and the fever disappears with the eruption. It occurs mostly in infants. It is not contagious and is prevalent mostly in the fall and winter. There is little enlargement of the lymph-nodes.

Occasionally rubella is characterized by a prolonged prodromal fever, but the other symptoms and its contagiousness separate it from roseola. I have seen rubella in several epidemics and also in isolated cases and yet the syndrome presented by roseola is different.

Roseola cannot be placed in the category of the exudative erythemata for obvious reasons. It is not a drug rash and it differs from the ordinary erythemata in being preceded for several days by fever.

OLDER DESCRIPTIONS

In Meigs and Pepper's text-book[3] the following description is found after describing different forms of the disease, some of which are clearly toxic erythemata: "Again, in a yet more marked form, which frequently but by no means exclusively occurs in warm weather, when it is styled roseola estiva and autumnalis, the eruption is symptomatic of a more definite constitutional disturbance. It begins with more or less chilliness, alternating with heat, with loss of strength and spirits, with headache, restlessness, sometimes mild delirium, and even, it is said, though we have never seen them, with slight convulsive phenomena. At the same time there is some slight febrile reaction. . . . After these symptoms have continued for two, three, four, or even six or seven days, the eruption appears first on the face and neck, whence it extends in twenty-four or forty-eight hours to the rest of the body. The rash resembles very closely in some cases exactly that of measles; but the catarrhal symptoms are absent. . . . The eruption is sometimes accompanied by itching, and sometimes by stinging pain, and the febrile symptoms generally continue, though moderated in a degree after the appearance of the rash; while in other instances the fever disappears entirely from that moment." I cite this to show that such cases have been observed, although many were confused with rubella, dengue and other eruptions.

Dermatologists probably do not see these cases, as the general practitioner treats them through the febrile stage for a variety of conditions and when the eruption appears there is such amelioration of the symptoms that counsel is not sought.

To show what difficulties in diagnosis are encountered in private practice a history of one of my earlier cases is given.

REPORT OF CASES

Case I.—J. C., a boy, 14 months old, had always been healthy. The nourishment was by maternal nursing for seven months from birth, since then cereals and cow's milk have been used with some additional food from the table. There has been no serious digestive disturbance. In May, 1908, the patient was suddenly taken with a high fever (104). The most careful inquiry revealed nothing abnormal beyond a congested throat. As the disease was regarded as an intestinal intoxication, castor oil and restricted diet was prescribed. On the following day the temperature was still high and the mother reported that the child was restless through the night. Again the physical examination revealed nothing. The ear-drums were not congested, there was no marked sore throat and no stuffy nose. On the following day a urinary examination for suspected pyelitis yielded no evidence of disease. A blood-count was made—leukocytes 11,500. The blood was also examined for the malarial plasmodia and another specimen of blood was sent to the health department for the purpose of a Widal test. On the fourth day we were still puzzled; but the mother telephoned that the baby seemed better. In the afternoon another message informed us that the patient had an eruption. The rash proved a typical rubella-like efflorescence. A prompt drop in temperature was synchronous with the appearance of the eruption.

During the last three years I have seen about thirty cases of this disease and a brief report of twenty-nine (Cases 4 to 33) is appended.

Of these twenty-nine cases fifteen occurred in girls and fourteen in boys. All the children were under the age of 26 months. Nine cases were seen in 1911, fourteen in 1912, and eight (to June 1) in 1913. Three cases occurred in January, six in February, four in March, three in April, one in May, two in June, one in

---

[3] Meigs and Pepper: Diseases of Children.

October, five in November and four in December. July, August, and September were exempt. In this seasonal occurrence roseola resembles the respiratory infections. All the cases occurring during the measles epidemic of 1913 were particularly watched for evidence of measles. Two other cases were excluded from the series because the catarrhal symptoms were marked and the fever did not fall with the appearance of the eruption, although Koplik spots were absent and no history of exposure to measles could be ascertained. During 1912 very few measles cases occurred in St. Louis. During these three years a few cases of German measles were seen in older children, but no general epidemic prevailed.

Gastro-enteric symptoms are rarely prominent. In three cases some diarrhea was noticed. This subsided with the appearance of the rash. One other case seen in June, 1913, was not placed in this series. This was a baby boy, 9 months old, who suffered from diarrhea and slight fever for three days. The stools were frequent and acid in reaction. On the fourth day an intense erythematous eruption appeared. It lacked the morbilliform character and was classified with toxic erythemata. I have met this particular syndrome in children above 2½ years of age only twice in the last six years.

CASE 2.—G. E., aged 9 years, was seen in August, 1907. The only prominent symptom was an elevation of the temperature (104). Fever with a temperature range of 102 to 104 continued for four days. Every effort was made to make a diagnosis without success. On the fourth day a few roseolar spots were seen on the abdomen and a Widal test was made. On the fifth day the temperature had dropped to normal and the boy felt well. The whole trunk was covered with circular spots resembling the rose spots seen in typhoid. There were no other symptoms.

CASE 3.—A. R., aged 14 years, has had measles and German measles. In May, 1913, the patient had an attack of fever, (up to 105), which terminated by crisis on the fourth day and a very profuse rash appeared which resembled rubella. There was no desquamation.

Although this particular syndrome was constantly watched for in older children, these two cases are the only ones seen which can compare with the clinical features as observed in infants. In the years preceding 1911, many such cases were observed, all in infants. It is reasonable to assume, then, that the disease with the clinical syndrome mentioned is almost entirely limited to infants, hence the proposal to call the disease "roseola infantum," a slight change from the older name.

This opportunity is taken to urge physicians to study this symptom-complex. It may prove to be a sporadic occurrence of rubella showing certain peculiarities in infants. At present we must regard it as an interesting clinical symptom-complex which to the practitioner deserves a distinct place.

CASE 4.—F. R., a boy, 2 years old, was breast-fed until 5 months of age and was then put on a supplemental feeding of modified cow's milk. There was no serious digestive disturbance until the child was 14 months old, when he suffered from a few attacks of indigestion as solid food was added to the diet. A slight idiosyncrasy against egg was shown at first but was soon overcome. On Nov. 20, 1912, the mother noticed that the child had fever. On the following day the temperature per rectum registered 104 2/5. During the height of the fever there was an expiratory grunt. The examination of the chest and body revealed nothing abnormal, but a congestion of the fauces was noticed. There was no enlargement of lymph-nodes, no eruption, no enanthem, and no ocular redness. Neither vomiting nor diarrhea had been present. Castor oil and aspirin were prescribed.

On the following day the cervical lymph-nodes were palpable, and the temperature was lower (100). No Koplik spots were present and there was neither eruption nor cough. On November 25, when the patient had been free from fever for ten hours, an eruption was first observed on the trunk. This became very profuse and confluent on the back, but was sparse on the extremities. The rash consisted of rose-red maculopapules. No arm sign was present. The tongue and throat were normal. The lymph-nodes were scarcely palpable. No more fever occurred and the eruption disappeared in two days.

CASE 5.—W. M., a girl, 5 months old, has been fed on diluted cow's milk. A restless and feverish condition existed for three days (March 7, 1911). A profuse morbilliform eruption appeared on the face and body. The temperature was normal. There were no Koplik spots.

CASE 6.—C. H., a girl, 5 months old, is suffering from chronic indigestion and malnutrition. The patient had been fed on Nestlé's food but was placed on pasteurized cow's milk one month before, on which the improvement was marked. Two pounds were gained in one month. (March 20, 1911.) A fever which lasted two days ended with a morbilliform rash.

CASE 7.—E. R., a girl, 20 months old, has been bottle-fed since birth. For a long time a digestive disturbance was present. The child suffered one attack of pyelocystitis. Nov. 17, 1911, fever suddenly appeared (103) No adenopathy, no catarrhal symptoms. It was at first thought to be a recurrence of pyelitis. November 20 typical roseola showed on back and face and a disappearance of the symptoms resulted. Three older sisters had no rash either before or after this illness.

CASE 8.—J. R., a boy, 7 months old, has been nursed by the mother supplemented by three bottles of milk daily, which are composed of ⅔ milk and ⅓ water, with 3 per cent. of milk-sugar added. The weight of the child is 16 pounds, 4 ounces. The last three nights the patient has been in a feverish condition, and is constipated; but had one loose stool yesterday (Nov. 7, 1911). Temperature, 99 2/5. A profuse morbilliform rash covers the trunk. There are no Koplik spots, no ocular congestion, no cough and no enlargement of the lymph-nodes. A sister, 3 years old, had no eruptive disease before or after his illness.

CASE 9.—J. T., a girl, 9 months old, takes two quarts of certified milk daily. The weight is 19 pounds. Fever has been present for two days, there is a slight cough and a slight discharge from the eyes. The mother gave one dose of a laxative nostrum. There is no fever to-day. There are no Koplik spots, and no enlargement of lymph-nodes. There is a profuse morbilliform rash on the body. An older sister, 3 years old, had no eruption before or after the baby's illness (Feb. 17, 1913).

CASE 10.—N. R., a boy, 8 months old, has been breast-fed entirely since birth. On the last two days fever has been present and several loose stools are passed daily. There is no fever to-day (June 18, 1911), but the body is covered by a morbilliform rash. One eye is slightly congested. The throat is congested, but there is no enlargement of lymph-nodes and no Koplik spots. No medicine has been given.

CASE 11.—A. M., a fine-looking boy, 11 months old, has been fed on dextrinized flour and milk since he was 2 months old. At 9 months some semisolid food was added to his diet. Fever has been present for two days, and the bowel movements are increased. There is no fever to-day (April 1, 1912), and the bowels have not moved. There is a morbilliform rash on the body. There are no enlargements of the lymph-nodes. A brother and sister had no rash before or after the baby's illness.

CASE 12.—E. C., a girl, 25 months old, has had a tendency to eruptions but no idiosyncrasy against any article of food. The patient is a healthy well-developed girl, and is on a general diet. The mother was disturbed about an eruption, Nov. 23, 1912. The child had fever for three days, and two days before the mother ascertained it to be 102. Restlessness at night is marked and waking is with a scream. No gastro-enteric disturbance has been observed. There is no cough. The rash consists of rose-red macular lesions, some elliptiform, others circular, and are most profuse on the trunk. The rectal temperature is normal. A slight sore throat is noticed, there are no Koplik spots, and no enlargement of the lymph-nodes.

Case 13.—M. W., a girl, 15 months old, is a healthy child, and the mother takes great precautions with the food. There are no other children in the family. The patient is suffering (Dec. 18, 1911) from a morbilliform eruption which is very profuse. There is no fever, and no enlargement of lymph-nodes or enanthem. Four days ago a fretful and feverish condition arose and food was refused. The temperature rose in the night, but the child was playful during the day, though waking several times during last night. The child is very irritable but has no cough, and has received no medicine. The eruption disappeared in three days.

Case 14.—W. M., a girl, 12 months old, has been bottle-fed since the age of 1 month, and has had repeated attacks of indigestion, also once before an erythematous eruption without fever. She is the only child in the family and is kept carefully isolated. Dec. 21, 1912, fever developed and the mother gave castor oil, which evacuated several foul stools. The rectal temperature (Dec. 23, 1912) is 99 2/5 and there is morbilliform eruption on the body. There is no enlargement of the lymph-nodes, and no enanthem.

Case 15.—E. L., a girl, 2 months old, breast-fed, had a mild attack of bronchitis when 1 month old. The child has two sisters and one brother, none of whom has recently suffered from a rash. Fever was present for four days, once rising to 101 4/5, when a morbilliform rash appeared. The fever subsided. There have been some dyspeptic symptoms, the acid dyspepsia of the young infant. Sodium benzoate was prescribed two days before the breaking out of the eruption. Recovery was prompt and no eruptive disease occurred in the family subsequently. (Dec. 5, 1912.)

Case 16.—F. P., a boy, 8 months old, is breast-fed at night, and is given milk and cereal mixture in the day time. There is no digestive disturbance. The temperature on Feb. 14, 1912, was 104. This fever continued three days and dropped to normal suddenly, when the baby broke out with a profuse morbilliform rash. There were no Koplik spots and no evidence of exposure to any eruptive disease.

Case 17.—R. B., a boy, 5½ months old, has been fed on condensed milk; the baby is fat, the weight being 17 pounds. Twenty teaspoonfuls of water and three teaspoonfuls of condensed milk are given every two hours. During the last week there was some constipation. High fever, 103, is present. The conjunctiva is slightly injected. The child is restless. Aspirin and sodium benzoate were given. Feb. 10, 1912, a profuse morbilliform rash appeared. According to the mother's statement, no fever has been present for three days. Neither measles nor German measles was observed in the city at the time.

Case 18.—K. R., a boy, 9 months old, brought to the city from the country. The child is afflicted with cerebral palsy and also suffers from recurrent attacks of bronchitis. (Feb. 27, 1912.) The patient has fever, the temperature rising to 102. Physical signs of bronchitis are present with asthmatic wheezes. Restlessness appears at night. There is no enanthem. Two days later a morbilliform eruption appeared; there was some coryza. The fever disappeared on the day before the eruption and the bronchitis also rapidly improved. Only creosote was given in this case.

Case 19.—E. H., a girl, 6 months old, is fed on cow's milk. The child has had fever for four days and is cross and restless at night. The bowels are somewhat loose. There is no vomiting and no cough. The patient feels better to-day (March 28, 1912). There is a profuse morbilliform eruption but no enlargement of the lymph-nodes. There is no other child in the family.

Case 20.—A. M., a boy, 3 months old, has been fed on the breast, supplemented by a certified milk and water mixture with cane sugar and sodium citrate. The child has been constipated but there is no vomiting. May 19, 1911, the patient began to be restless and feverish. The rectal temperature was 101. Nothing abnormal has been discovered. The baby was put on barley water and breast-feeding. May 25 a morbilliform eruption appeared. Some curds showed in the stools. Half a pound has been lost in weight. There is no fever.

Case 21.—S. G., a boy, 5 months old, is breast-fed supplemented by cow's milk, diluted. (Dec. 8, 1912.) Fever (103) is present. This continued for three days. On the fourth day a maculopapular eruption appeared, which covered the trunk and extremities. The temperature was 98 4/5. There was slight enlargement of the lymph-nodes. A slight digestive disturbance is present. The baby is breast-fed, but gets in addition three bottles of certified milk modified with water and cane-sugar.

Case 22.—B. K., a girl, 5 months old, is entirely breast-fed. The child has had fever all night (Feb. 9, 1913). There is no coughing or sneezing. The rectal temperature is 102 3/5; the throat is congested but there is no ear trouble. The fever continued on February 10, with no change in the physical condition. There was no digestive disturbance. February 11, the temperature has subsided. There is a morbilliform rash all over the body and also on the face. There are no Koplik spots. A slight enlargement of lymph-nodes shows. The baby has a sister 3 years old who has not had measles or rubella. The latter had no symptoms of an eruptive disease in the following month.

Case 23.—A. G., a boy, 1 year old, was fed on malted milk since 3 weeks old, and was also given orange juice and prune juice. The child had an attack of diarrhea at 11 months, when first seen. There is marked evidence of rickets. The food was changed to milk and barley-water with malted milk; also bread and vegetable soup were taken. Improvement was rapid on this food. Three weeks later the boy was suddenly taken ill with a temperature of 105-2/5. (Oct. 15, 1912.) The fever continued for three days, when an eruption appeared on the abdomen. This maculopapular eruption became very profuse in the next twenty-four hours though not much appeared on the face. Confluent dusky-red patches appeared over the buttocks. The temperature became normal October 19. There were no Koplik spots and no catarrhal symptoms. This boy was very sick.

Case 24.—B. S., a girl, 10 months old, had severe gastro-enteric intoxication during the past autumn. (Jan. 1, 1912.) The child had high fever for two days. The temperature now is 103 3/5. There are no catarrhal symptoms and no digestive disturbances. The throat is about normal. The ear drums are in normal condition. The diagnosis was very puzzling. (January 2.) The baby is broken out with a macular eruption; the lesions are circular, large and small, and rose-red. The temperature is 100 2/5. There are no Koplik spots and no catarrhal symptoms. The child was well the next day, the rash fading. There was no desquamation.

Case 25.—J. H., a girl, 1 year old, had been breast-fed until recently but is now on a mixed diet. The bowels were loose three days ago and have been slightly loose since. There has been no vomiting. High fever was present for two nights (102), the fever continuing for two days longer. (April 9, 1911.) Morbilliform eruption has appeared. There is no fever and the pulse is slow. Diarrhea has ceased. The child recovered promptly of all symptoms.

Case 26.—L. G., a girl, 7 months old, has been fed on a whey and milk mixture. As a young baby the child suffered from severe vomiting, though it looks well now. The patient (Jan. 21, 1912) has had severe catarrhal symptoms for three days—other members of the family have the grip. The baby has had fever (102). A slight diarrhea is present. Roseola has appeared on the body to-day and a rapid defervescence of the symptoms has followed. This baby had several drugs for its "cold." It may have been a symptomatic rash.

Case 27.—E. H., a girl, 7 months old, was nursed for three months, then fed partially on the bottle—a mixture of milk, water and milk-sugar being given. The child did well on this food. June 10, 1912, the baby began to be restless and feverish, and had one fermented stool. The patient was put on barley-water, June 11. The temperature rose to 103 in the afternoon. There was no diarrhea and no catarrhal symptoms though there was a slight sore throat. June 12, a very profuse eruption appeared which looked like German measles. The temperature is 100. There are no Koplik spots. The baby has lost its drowsiness. A sister, aged 5, had no such eruption before or afterward.

Case 28.—C. T., a boy, 10 months old, has a sister, aged 5, who had not had rubeola or rubella. The child has been restless and feverish for several nights. To-day (March 28, 1913) he is broken out with a morbilliform rash. There is no fever and no catarrhal symptoms or digestive disturbance. The child has been fed on milk and barley-water.

Case 29.—A boy, 13 months old, has been fed on some milk and solid food, including potatoes, bread, oatmeal gruel, baked apple, beef juice and cow's milk to which extract of malt has been added to prevent constipation. (April 17, 1913.) The patient has had fever for three days which ranged from 101 to 104. There is much restlessness, but no sore throat, no cough and no enlargement of the lymph-nodes. A morbilliform rash has appeared. There is no fever. The recovery was rapid. There are no other children in the family. The child lives in an apartment.

Case 30.—B. L., a boy, 18 months old, took scarlet fever of moderate severity Feb. 1, 1913. March 4, 1913, when he had recovered almost completely, the temperature rose to 103, and a variable temperature persisted for three days. There was a slight coryza and some cough. A fine roseolar eruption appeared on the body. The temperature was 101. There were no Koplik spots. The temperature was normal on the following day. There is no other child in the family.

Case 31.—L. M., a boy, 21 months old, has been fed on a mixed diet. Feb. 13, 1913: The fever began four days ago and the child has since been restless. The mother noticed a rash to-day. Maculopapular spots cover the trunk and limbs but few are on the face. There are no Koplik spots and no fever, but there is a slight enlargement of the lymph-nodes. No sore throat is present. The child is suffering also from a frost-bite on the left cheek. There is a younger baby brother. No more fever is shown. There are a number of cases of measles in the neighborhood.

Case 32.—E. M., a girl, 15 months old, has been on a mixed diet, and is well nourished. The baby lives in an apartment and has had high fever for three days. There is a slight exudate on one tonsil. The child is restless at night. The temperature is normal to-day. A morbilliform rash covers the whole body but there is little on the face. There was a rapid recovery without drugs. She had received two doses of acetphenetidin before the appearance of the eruption. No digestive or catarrhal symptoms were observed. There is only one child in the family (March 28, 1913).

Case 33.—B. S., a girl, 3 months old, breast-fed, had fever for three days when the rash appeared. The temperature was still 103 when the eruption was noticed. The next day the fever had dropped to 99½. The rash is morbilliform and erythematous. There is intense congestion of the skin. The infant is restless. There are slight catarrhal symptoms. No Koplik spots are present. The stools are frequent and watery (Jan. 12, 1912).

ABSTRACT OF DISCUSSION

Dr. F. P. Gengenbach, Denver: It is important to recognize this eruption, especially in hospital work. I have seen several of these cases in children's hospitals in Denver. Needless to say we were all much alarmed. I think that in most cases the patients do not have such high fever. When they do, we think of scarlatina. As Dr. Zahorsky has said, these cases have never proved contagious. I have never seen other cases develop in the hospital after one of these cases. They do frighten us, however, and I think that we should be able to recognize them.

Dr. H. W. Cheney, Chicago: I wish to add to Dr. Zahorsky's statement that I have seen in recent years a number of these cases corresponding to his clinical picture, coming on with this indefinite fever and then a rash. I have been inclined to classify them under rubella or German measles and think that perhaps we had better cling to that term rather than make a new classification which might confuse many who are not careful observers. We know that German measles is not always contagious. Then, too, in German measles there is frequently fever several days before the eruption. I should be inclined to classify these as typical cases of rubella.

Dr. John Zahorsky, St. Louis: As I mentioned, these cases are usually diagnosed as German measles, but the syndrome is so peculiar and typical that I think it deserves a special place. We might regard it as German measles until we can establish a definite place for it. Its contagiousness has never been demonstrated. German measles and measles are contagious diseases, but these roseola cases are not contagious, so far as my observation goes. These cases show a clinical syndrome so clear and distinct that it should always be borne in mind when trying to make a diagnosis. Therefore, I think that it deserves a place—temporarily at least.

JOINT-DISEASE DUE TO INFECTION FROM OTHER PARTS OF THE BODY*

J. W. COKENOWER, M.D.
DES MOINES, IOWA

The frequency of joint-disease and its often uncertain etiology constitute a problem whose factor has contributed largely to the unsatisfactory differential diagnosis of the various kinds of joint ailments. After looking up the literature on the subject for the past four years and failing to find scarcely anything published on it, I wrote a number of orthopedic and general surgeons for clinical reports. These unpublished reports have assisted materially in the preparation of this paper.

I believe that our failures in treating joint-diseases are due more to wrong diagnosis than to improper treatment, and back of this a lack of the knowledge of the anatomic structure of the joints as well as the pathology of the disease.

The differential diagnosis may be specific, pathognomonic, negative by exclusion, collateral or by exhaustive history of the case from infancy to the present time.

It will often be necessary to have regional experts to assist, and with the help of roentgenography and bacteriology we have the best means at our command; but we must not forget, omitting trauma, that arthritis is only a symptom of a disease or diseases whose real nidus is in some distant part of the body.

The presence of a urethritis or suppurating antrum may be the only diagnostic points between two cases in which the patients are suffering from apparently identical joint lesions; but the one is gonococcal, the other septic; hence the antrum in one and the urethra in the other must receive our attention in order that we may obtain satisfactory results. Syphilis and certain other diseases are quite different after the initial stage, because it is then a septicemia and has no known nidus, but consists in polymorphic manifestations, of which arthritis is one.

There can be no doubt that in chronic joint cases the diagnosis in children lies chiefly between tuberculosis, on the one hand, and the manifestations of sepsis, rickets, congenital syphilis and coxa vara, on the other; and in early adult life special forms of septic infection from gastro-intestinal and genito-urinary tracts are most common, while in late adult life chronic septic infection of the mucous tracts of nearly all parts of the body must be considered and our success will be measured by the attention given them.

I wish to emphasize the importance of the oral cavity as a source of arthritis. The absence of all the teeth without replacement by artificial ones, is a sure proof of many years of oral sepsis. Gastro-intestinal sepsis and diseased tonsils and teeth make the mouth a septic laboratory for which in many cases the joints must pay the debt.

---

* Read in the Section on Orthopedic Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

Therefore, the differential diagnosis of arthritis frequently depends, not on the examination of the local condition, but on the presence or absence of preceding or associated lesions in other parts of the body.

Another condition of the joints which must not be overlooked in our diagnosis, because it is often taken for inflammation when in fact it is not, is edema due to effusion. Joints depending on muscular tonicity are more frequently invaded. To illustrate briefly: An inflamed bicuspid tooth-socket will produce edema of the lower eyelid, and the collateral edema will be in proportion to the inflammation; hence, fluid by diffusion extravasates into not only adjacent, but also remote tissues of the body, and when prolonged will produce proliferation of the endothelium of the lymph-vessels and capillaries, resulting in permanent thickening of tissues. I believe that the same thing exists in joints and is not primarily due to disease of these structures.

Dr. George W. Crile reports a number of cases of joint disease due to endocarditis and streptococcus infection from other parts of the body and occasionally from acute abdominal infection.

Dr. Charles F. Painter reports having seen a number of cases in which arthritis symptoms were relieved with such promptitude after treatment of the tonsils and teeth that he was convinced that the infection was due to that source.

Dr. Roswell Park writes, in substance, that joint-disease due to infections from other parts of the body, especially the oropharyngeal cavity, is a subject much neglected, but certainly exists to a great extent; and the modern etiologist is proving this fact. Yet no one has written on the subject, but few authors have done more than refer to it, and Park admits that he is one of them.

Dr. John B. Murphy, one of our best known surgeons on joint-diseases and articulations, fully concurs with the general consensus of opinion on joint-disease due to infection from other parts of the body.

Dr. A. H. Freiberg has frequently succeeded in determining an antrum of infection, the removal of which cleared up cases of infectious arthritis. The most notable examples of this kind have been in connection with the genito-urinary tract.

In case of chronic infectious polyarthritis I believe that we shall have to depend on the increase of diagnostic skill in order to obtain better results; yet there is no doubt, in my mind, of the relation of these cases to an original infection somewhere else in the body.

Dr. A. E. Barker states that among the many non-traumatic ways in which joints may be infected through the blood-stream, less attention has been given to the entrance of bacteria from the gums than the subject deserves.

Every one is familiar with synovitis following gonorrhea or other forms of septic catarrh of the urethra, vagina and other parts of the body, but in many instances it may be difficult to trace the joint trouble to any of these; so it is well to examine closely into the condition of the oropharyngeal cavity in every attack of synovial inflammation of non-traumatic origin, because the so-called hemogenic infectious organisms introduced into the system through a very common septic lesion, pyorrhea alveolaris, are carried into the blood-stream and excite in the lining membrane of a joint-cavity an inflammation causing hypersecretion and ultimately suppuration.

Dr. H. M. Sherman reports that he believes there is a close relation between diseases of the joints and infections from other parts of the body, especially the tonsils and alveolae.

Dr. C. Stewart Wright of Toronto reports a number of cases of joint-diseases which proved to be due to infection from the tonsils and teeth, and concludes that they are the most frequent source of infection and believes that all chronic joint-disease, excluding tuberculosis, may be due to some disease, or some focus of infections elsewhere.

Dr. Arthur Steindler reports a number of chronic joint-disease cases, due to infection from the oropharyngeal cavity.

Case 1.—M. M., aged 20, March 25, 1912, had been treated previously for chronic arthritis of the knee, considered to be tuberculous, for six months. Then, following an attack of tonsillitis, the condition of the knee became suddenly worse, with acute swelling, soreness and tenderness. A few days later the characteristic spindle-shape swellings appeared at the knuckles. The tonsils were removed and under massage and bath treatment both the enlargement of the finger-joints and the acute swelling of the knee disappeared. The patient at present is fully recovered with almost normal range of motion and slight muscular atrophy.

Case 2.—Man, aged 28, referred by Dr. C. W., had an attack of rheumatism four years ago affecting both feet, especially the left. They were swollen and he was unable to walk for about four months, during which time he was treated at his home hospital, after which he returned and was able to resume work. He continued to work for over a year, and then had another attack more severe than the first, and for several months was under the care of his family physician. During that time his ailments had increased in spite of all the medicines, antirheumatic and otherwise, which had been prescribed, and then he was sent to Des Moines and referred to me.

A careful examination revealed no positive etiology, except that the oropharyngeal cavity showed quite a number of diseased teeth and pus exuding from gum margins. Believing I had found the cause of the trouble, I instituted the following treatment:

1. Dental treatment of the teeth and gums.
2. Local treatment of feet, hot fomentations, massage, uniform warmth and rest.
3. No medicine except regulating secretions, excretions, and plenty of water.

The dental report was nine teeth extracted and twelve requiring treatment. The gums and abscesses responded promptly to the treatment, and the striking feature was that all this time there were no seeming constitutional subjective symptoms.

The result was so satisfactory, after the removal of the cause, that in a month the patient was able to walk with ease, without pain or swelling, with the feet comparatively flexible, and no retrogressive symptoms since. Nature seems to be restoring normal conditions as fast as such fibrous changes permit.

Case 3.—Mrs. D., aged 45, had an attack of rheumatism, affecting the right knee, in June, 1911, causing her to be confined to the bed for several weeks, during which time antirheumatic and local treatments were given. For a while she seemed better, but soon had another attack worse than the first. She consulted physicians in Omaha and Chicago, who all agreed as to the rheumatic symptoms, but none seemed to locate the focus of infection. Returning to Des Moines she went to Mercy Hospital, and a thorough examination was made, including teeth and tonsils. Both were diseased and were the only pathologic conditions found which might be taken as the real cause of the joint trouble. I called in oropharyngeal specialists, who removed the tonsils and diseased teeth. During the three weeks following the patient improved rapidly and left the hospital in good shape and has done her accustomed work ever since, now almost two years, with no return of any joint-trouble.

CONCLUSIONS

1. The failures in treating chronic joint-disease are largely due to incorrect diagnosis.

2. All joint disease not traumatic or tuberculous is due to infection from other parts of the body.

3. No diagnosis is complete, especially when there is doubt, without the inclusion of the oropharyngeal cavity.

ABSTRACT OF DISCUSSION

Dr. Henry Ling Taylor, New York: In the study of joint disease, we should never employ the term "rheumatism" as a scientific name. It is not merely a matter of esthetics, but is exceedingly desirable on practical grounds, that we should abolish this term entirely; because when a polyarthritis is designated "rheumatism," a certain line of treatment naturally follows—the iodids, the alkalies or the salicylates, all of which are bad for chronic arthritides.

There is one point in Dr. Cokenower's paper, however, to which I think we can take exception; and that is the point of his having instanced endocarditis as a cause of arthritis. It seems to me that both endocarditis and arthritis are due to the same cause, namely, a focus of infection in the mouth, the antrum, the urethra or elsewhere in the body; that, at any rate, is my experience. We should not forget, however, that many cases are treated most searchingly and scientifically, but absolutely fail to respond to these methods of treatment. I have seen many cases that were handled by the best men in the country, with every opportunity for scientific research and painstaking treatment given the patients, who had had their teeth put in order, their tonsils removed, their colons elevated, and everything that one could possibly think of done for them, without the slightest benefit. I have now under observation a case of extreme polyarthritis —so-called arthritis deformans. The patient had had the disease first in one finger-joint. She had her tonsils removed and afterward became rapidly worse, so that now nearly all of her joints are affected. This, of course, is nothing against the author's position, but I do think that we must admit that there are many cases in which we are unable to obtain success along these lines, and that, in the present state of our knowledge, it is best not to claim too much.

Dr. Wisner R. Townsend, New York: I recently saw a patient, a youth of 17 years of age, in good physical condition otherwise, who had a sore throat. His physician believed that it was a case of diphtheria and ordered the administration of five thousand units of antitoxin, obtained from the board of health. This was given; yet the bacteriologic and microscopic examinations showed no bacteria, and in a few days the patient was apparently well. Two days later his ankle-joints began to swell; the swelling was accompanied by pain and a petechial eruption. This disappeared after a time. The temperature was 103 F. The condition was what would be termed a "rheumatism" of the ankle-joints. The interesting point is that within a week this young man's wrists, as well as the carpal joints, became swollen and painful; the question arose whether the condition was an infection from the pharyngitis or whether it was a condition of anaphylaxis caused by the diphtheria antitoxin. It is well known that the system of many persons will not tolerate horse-serum, which produces this condition in them. The men best qualified to speak about it thought that it was a case of anaphylaxis; we thus have another condition to consider when we meet with joint symptoms. If nothing had been said about antitoxin in this case, there would have been nothing to suggest that that was the cause of the condition, and the diagnosis would have been erroneous or, at least, incomplete.

There is another condition causing joint symptoms that has not been dwelt on sufficiently. Recently, in the city of Cortland, N. Y., we had four hundred cases of milk infection, the patients being affected with sore throat accompanied by arthritides in many instances. The throat affection was supposed to cause the joint symptoms and was due to a bacillus found in the milk. This, in turn, was due to an irritation of the teats of two cows. The infected cows were killed and the epidemic stopped. It will thus be seen that when we seek the origin of many of these conditions we must go further than the buccal cavity, although we must not, of course, forget that.

Dr. Fred J. Gaenslen, Milwaukee, Wis.: I should like to know what has been the experience of other men as to the effect of opening and irrigating joints in the type of cases which Dr. Taylor refers to, cases in which thorough examination does not reveal a focus of infection. Does irrigation of one or two joints most severely affected have a beneficial influence on the other joints involved?

Dr. Emil S. Geist, Minneapolis: It is my opinion that there are many cases of polyarticular trouble that we do not call infection because the primary condition, the infectious focus, is beyond our reach. When we do help, it is because the original focus of disease can be reached with an instrument six inches long. In other words, there are often hidden foci, difficult of access, that we are unable to remove.

I have learned that it is necessary to place these persons in the hands of the most competent specialists in order to obtain satisfactory results. A great many things that escape the ordinary dentist, for instance, will be found by the man who is accustomed to treating pyorrhea. Since I have learned to be particularly careful in this respect I have obtained much better results.

Dr. Albert H. Freiburg, Cincinnati: It is my experience that many cases, which in their clinical history are undoubtedly of the infectious type, fail to improve after we have attacked what we suppose to be the atrium of infection, or they reach a point beyond which we cannot bring about improvement in them. There are three reasons for this, the first being that a person often has more than one atrium of infection in his body, and that which we attack, because it is the most evident, is not necessarily the one from which the patient is absorbing the poisonous material. The second reason, I believe, is that when the polyarticular disease has been in existence for a certain length of time, pathologic changes have occurred in the joints in consequence of the infectious material there, and these require a separate and distinct treatment other than the removal of the atrium of infection, while we are prone to give our patients insufficient treatment after the atrium of infection has been removed. I have made a number of experiments with the material called fibrolysin, without much success. I have been successful only in cases of polyarthritis in which we believed that we had discovered the real atrium of infection. In these cases, after this had been removed and the patient reached a point at which improvement no longer took place, the administration of fibrolysin had a sufficient effect to cause improvement to begin. The third reason is that the atrium of infection may give little evidence of its presence and none that can be discovered by gross means; we sometimes have to resort to most thoroughgoing measures to discover where it is. A case in point was that of a married woman. She came to me with a chronic polyarthritis of the infectious type. She declared that she had no infectious disease in her body, so far as she knew, and we could discover nothing by examining the usual sites of infection or by examination of the genital tract. I had her blood examined, and the report came back negative for everything but the complement-fixation test for gonorrhea, which was positive. The woman had a small fibroid. Laparotomy was done and fluid was found in both tubes. Unfortunately, the specimens were not handled properly, but were put in formaldehyd immediately. Therefore I cannot say whether or not any bacteria would have been found in the fluid. The tubes were removed and the patient made a good recovery. She had believed that she was the subject of arthritis deformans and was doomed to become a permanent cripple. If we can obtain a result like that once in a while, it is worth making an effort for; and that such a result has been attained shows that we are on the right track in believing that the disease is infectious in origin and that we cannot cure such cases without disposing of the infectious atrium. We may therefore be able to do more for this class of cases which has puzzled us for so long.

Dr. Roland Meisenbach, Buffalo, N. Y.: I have for a long time been interested in those cases in which we attempt unsuccessfully to find the focus of infection, although we feel certain that it must be in several parts of the body—in the teeth, the intestines or the lungs or joints. All of those who examine roentgenograms carefully find that there are usually *foci* present in the lungs or other parts of the body, which in many instances are evident in the roentgenograms. I agree, in the main, with Dr. Cokenower's paper, but at the same time I am not willing to acknowledge that most of these cases of joint trouble are of the infectious variety. I think that we shall find by searching that many which are considered infectious are in reality due to a metabolic condition. I have had complete metabolism investigations made in many doubtful cases and have become accustomed to make the division on a somewhat arbitrary basis; for instance, those cases with temperature elevation are usually considered infectious, while those without temperature elevation may be considered metabolic. It is pleasing to see how many things in regard to the infectious type may be learned by the study of focal localization. I have for a long time been sending my patients to dentists, but have not had autogenous vaccines made from the teeth, for the reason that when the teeth are examined microscopically nine out of ten times the infection will be found to be caused by streptococci and staphylococci, so that it is a question which of these autogenous vaccines to inject. Dr. Cokenower's paper strongly suggests, I think, that the class of cases which come under the ruling of this paper are those which we see constantly, cases with peri-articular thickening and with slow, steady infection involving one or more joints, and in which the toxins and not the bacteria have entered the joint. In these cases the toxins are derived from different foci, which may occur in the lungs, teeth, genito-urinary tract and many other places.

Dr. J. D. Griffith, Kansas City, Mo.: I do not see why Dr. Cokenower excludes tuberculous infection, because I am satisfied that most of us have had infection of the tonsils and lymph-nodes. Why, therefore, should he exclude the tubercle bacillus as the cause of infection in these cases?

Dr. Clarence B. Francisco, Kansas City, Mo.: I wish to speak on the association of the tuberculous process with the infectious process. In going through the hospitals you are often shown patients with joint tuberculosis who have made remarkable recoveries. It occurs to me that possibly these joints were not really tuberculous, and that possibly the process seemed to localize itself in one joint and was mild in the other joints. At the Mercy Hospital at Kansas City, I have made all the tests on cases that came in looking like straight tuberculous hip, for example. We had three patients that had a little temperature and all signs of a tuberculous hip, yet the von Pirquet test was negative, and the blood analysis suggestive. When put in fixation, the patients would be relieved of their symptoms in a few weeks. The symptoms would return, however, if the fixation was removed. On having the tonsils of these patients removed or their teeth attended to, we found that it did not matter whether the fixation remained off or on; they were apparently cured. It occurs to me that some of these infections may localize in a joint and simulate a tuberculous process.

Dr. Gilbert L. Bailey, Oak Park, Ill.: Certain of these infectious types do localize in one joint, especially in the knee or hip, following typhoid, streptococcic and other infections, many of which have not yet been differentiated.

The question was asked as to the treatment of localized joint infections and the advisability of draining them. The course I have followed in treating these cases is, first, to remove the focus of infection, when it can be found, and to use the proper serum therapy, when the agent can be identified. Locally, traction is made to separate the inflamed joint surfaces and a splint applied to insure rest. If this is not effective in relieving the symptoms, tapping or, if suppuration is present, opening and cleansing the joint should be done as soon as possible as in any other abscess.

Dr. J. W. Cokenower, Des Moines, Iowa: My statement that endocarditis causes joint disease was a quotation from Dr. G. W. Crile of Cleveland, Ohio, as I have had no cases of that kind.

Another question was with regard to whether it is possible for us to ascertain definitely the nidus of infection. I do not quite agree in regard to that. I spoke in my paper about calling in experts. I never thought that I was competent to take up all the special lines of investigation necessary in these cases. There were specialists in other lines, and I consulted them. Whenever our treatment is not a success, I always think that the diagnosis is incorrect, and that it is time to stop and investigate. By doing that we have better success in our treatment.

I did not endeavor to convey any idea about treatment, for the paper was written simply with the one object in view of urging the necessity of finding out what we have to treat, and after we have done that it is my experience that the treatment is comparatively plain.

THE INJECTION TREATMENT OF TUBERCULOUS JOINTS *

LEONARD W. ELY, M.D.
SAN FRANCISCO

The treatment of all joint diseases, whatever their cause, seems to follow certain well-defined lines and in rather definite order. The first and second expedients resorted to are external applications and internal medication. If these fail we turn to the third, incision and drainage. This appears logical. If a joint is swollen, painful and inflamed, we infer that there must be something inside that is causing the trouble, and that if we let this something out the disease will heal. Failing here in our efforts we resort to the fourth, aspiration and injection. Here again we seem to be on safe ground. If we can withdraw from the joint cavity the products of disease and then can inject some beneficent substance, we shall be able to cure the disease. If by any chance, after trying all these methods of cure, we have not found the specific sought for, we are often obliged to study carefully the disease before us, its cause, pathology and course, and by hard work to devise a rational cure.

This entire routine is not observed in all joint diseases. In joint syphilis, treatment by internal medication and external applications suffices for a cure. In pus joints incision and drainage offer the best prospects.

For the treatment of tuberculous joints external applications without number have been tried in vain and internal medication had its day and has been cast aside. Tuberculous joints are daily being laid open and drained, but the operation has been proved worthless and, happily, is becoming obsolete.

The employment of injections in tuberculous joints goes back for over thirty years. The first mention I can find of it is an article by Mikulicz,[1] written in 1881. Von Mikulicz, working in Billroth's clinic, used iodoform. Many other substances have been used since, among them bone charcoal, iodin, phenol (carbolic acid), arsenious acid and corrosive sublimate, acidulated solution of calcium sulphate, zinc chlorid, balsam of Peru, naphthol camphor and formaldehyd solution.

---

* Read in the Section on Orthopedic Surgery of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

Of all these substances iodoform has been advocated most strongly, persistently and enthusiastically. Its history interests us the most and is extremely instructive. Mark well how its advocates cling to it firmly, even after the rationale of its use has been shattered. This is often so in medicine. When authority reaches a conclusion, its conclusion continues to be accepted even after its premises have been proved false.

Mikulicz praised the "astonishing usefulness" and antiseptic action of iodoform. Baumgarten,[2] six years later, showed that it was not an antiseptic or bactericide. A change of front became necessary. Accordingly we find the statement that whereas iodoform may not be an antiseptic when employed in open wounds in which we can see it, nevertheless its nature changes when it is injected deeply into the tissues where we cannot see it, and it becomes again an antiseptic. Those who wished to use a true antiseptic, however, abandoned iodoform and adopted other agents.

Fraenkel,[3] in 1900, tested experimentally the action of various injected powders on the healing of wounds and used bone charcoal clinically in bone tuberculosis. Unsterilized iodoform and other powders provoked suppuration. Sterilized iodoform and certain other sterilized powders, notably bone charcoal, promoted healing. Fraenkel found that charcoal was more efficacious than iodoform and reasoned quite logically that no specific virtue resided in any of the powders, but that their action was purely mechanical, promoting healing by their irritation. He, like others, frightened apparently by authority, deals gently with the malodorous powder. If we adopt Fraenkel's chain of reasoning, we must acknowledge that sterile foreign bodies promote healing of a tuberculous lesion. If we reject them, we reject sterilized charcoal and iodoform as being useless.

Iodoform has been used in solution in ether and alcohol, and in suspension in water, in glycerin and in oil. Krause,[4] one of its most eminent advocates, published his results after one and one-half years and had a high percentage of cures. He was confirmed in his favorable opinion because in one patient who had been injected and who later had an arthrectomy performed, "the synovia in many places did not show the picture of tuberculosis." We know now, however, that this is often true in patients who have not been injected. The synovia in many places may not show any signs of tuberculosis, especially on its surface.

Most of Fraenkel's cases were of cold abscess. He called them "permanently healed" when they had been apparently healed for three months. It is now well known that cold abscesses often disappear under the simple treatment of aspiration or without any treatment.

One of the strongest arguments that could be brought forward for the use of iodoform was that tubercles were absent from the wall of cold abscesses whose cavities had been filled with an iodoform mixture, but since we have learned that tubercles are not ordinarily present in these walls, this argument loses force.

If we examine carefully the evidence for iodoform after thirty-two years of trial we find that it consists almost exclusively of unsupported clinical opinion. This does not necessarily condemn it, but when an approximately equal weight of unfavorable clinical opinion is produced on the other side, we are justified in demanding some tangible proof of the usefulness of iodoform. Failing this, we should adopt a form of treatment whose efficacy rests on something else than contradictory clinical experience. Iodoform is not widely used in this country at present, except by those who possess an extreme reverence for foreign authority.

The other substances mentioned rest their claims on much the same basis as does iodoform. Most of them have been advocated vigorously for a while, and then have lapsed. The later ones, notably formaldehyd solution, are still being tried.

It is as rational to attempt to cure a tuberculous joint by injection of the synovial cavity, as to cure a tuberculous lung by injection of the pleural cavity.

There are two different ways of viewing tuberculous tissue, one as essentially diseased tissue which must be eradicated completely at any cost, the other as Nature's reaction against the presence of tubercle bacilli. If we adopt the latter view we shall discount immediately the ability of any substance injected into a joint to destroy the infection, and shall ascribe any healing effect it possesses to its aid to Nature in the healing processes she has already inaugurated. Foremost among these is the production of fibrous tissue.

Leland Stanford Junior University, College of Medicine.

ABSTRACT OF DISCUSSION

Dr. Fred H. Albee, New York: I should like to ask Dr. Ely whether or not he did any pathologic work on the effect of formaldehyd.

Dr. John Prentiss Lord, Omaha, Neb.: I have given some attention to the theories of Dr. J. B. Murphy in regard to the use of various substances for increasing the local blood-supply and the leukocytosis—the reaction occurring to organisms that infect the knee-joint, and more particularly the pyogenic group. Dr. Ely concludes that this effect can be only mechanical; I wonder whether an acute suppurative knee would contain the germs on the surface and would be more readily affected by such a process than by a tuberculous process which seems to be more deep-seated and to have produced a greater infiltration, so that any mechanical or irritating agent could have but a surface effect, as it were, on the joint. We can conceive that it would be beneficial, if the original infection were in the joint, and if the supply of infection were neutralized or shut off, in removing the primary focus, in order that the secondary changes might disappear; just as on the removal of primary tuberculous foci elsewhere, we find the process clearing up in a remarkable way. It would seem to me that we are perhaps dismissing this matter in a too self-confident way when we conclude that it is a purely mechanical effect, although Dr. Murphy firmly lays down the dictum that this is the best treatment for a suppurative joint, and in some of his cases would seem to prove the truth of that assertion. Dr. Ely, on the contrary, lays down the dictum that a suppurative joint should be opened and drained and that that is the best treatment; while Dr. Murphy states that it is the worst treatment—that to open and drain a suppurative joint means to produce a stiff joint. I have seen him show cases in which, by the bismuth-turpentine or the formaldehyd-glycerin treatment, joints were preserved as useful subsequently to that diseased condition.

Dr. J. D. Griffith, Kansas City, Mo.: If I understand Dr. Ely correctly, he takes the ground that this tuberculous

deposit is in two places, the synovia and marrow; his idea is that you do not reach the disease by the injection of iodoform, or anything else, where you can destroy this tuberculous process. Is that it?

DR. ELY: Yes.

DR. GRIFFITH: If I understood Dr. Murphy's idea correctly, his injection of a 2 per cent. dilution of liquor forhaldehyd in glycerol (glycerin), more than twenty-four hours old, is for the purpose of reaching the joint surface itself. I do not think that Dr. Murphy would maintain that the injection of formaldehyd, after the tuberculosis has become marked, would eradicate or stop the process. This is not a suppurative joint, as a rule. There is not a mixed infection, but only the tuberculous disease. Mixed infection does not occur until after the disease has progressed. By opening the joint we expose it to infection. Synovial involvement occurs generally in persons beyond the age of adolescence; but in the young child you find the epiphyseal involvement just commencing in the bone. I do not believe that you can reach the point of involvement in either adults or children, because the grown man does not come to you for treatment until the process has gone on to the point of erosion of the cartilage and probable bone involvement, and in the child you cannot reach it because you do not reach the disease of the bone by the injection.

DR. LEONARD W. ELY, Denver: I have never used formaldehyd. While it does not strictly bear on the subject of the paper, the introduction of Dr. Murphy's view is, I think, valuable at this time. In all this work we must discount what a man says. That is, we must make him prove his statements. We must not be overcome by the eminence of his name. It seems to be pretty thoroughly established that a joint may contain a few white cells on aspiration, and yet recover promptly and with good function under the treatment by aspiration; but I do not believe that if it contains puscocci this treatment by aspiration will cure it, any more than it would cure acute abscess anywhere else in the body. Murphy bases his whole theory on an absolutely erroneous idea of the pathology of the disease. In the first place, there are no endothelial cells, delicate or otherwise, on the surface of the synovial membrane, because the synovia is not an endothelial membrane at all, but a connective-tissue membrane. On its surface, or rather in its substance near the surface as seen under the microscope, there are numbers of small, round cells. They are not pavement endothelium at all. That is his first error. His second idea is that the exudate in the joint destroys these cells and damages the cartilage. Probably every one of you has opened a chronically diseased joint, full of fluid, tuberculous or otherwise, and found the cartilages perfectly smooth, glistening and in good condition, if the joint has not been immobilized. In other words, fluid in the joint does not damage the cartilage at all. You often find, too, that instead of the delicate "endothelial" membrane being damaged, that is, the synovia being destroyed, it has, on the contrary, proliferated. The fluid causes the synovia to proliferate and form folds and reduplications. Either there is an exuberant synovia or it has been replaced by fibrous tissue. Murphy makes his third error by saying that he reduces this damage to the cartilage by extension, thereby diminishing the pressure of the fluid on the cartilage. Assuming that you could pull a joint apart and that it was full of fluid, the more you pulled the more you would exert pressure by the fluid on the cartilage. The fluid in the joint is not responsible in any way for the damage to the cartilage. The damage is done by disease in the bone-marrow beneath it. If you make an opening in one of these acute pus cases you will find the marrow badly diseased, thus depriving the cartilage of its nutrition and killing it. We assume that the fluid exudate is what is causing the disease in cases of joint involvement; but we no longer assume that in the case of the lung. We do not think that by withdrawing fluid from the pleura we can cure disease in the lung. The fluid accumulates in the joint from a purely mechanical reason—because it cannot accumulate anywhere else. The fluid, however, is not the disease, but a symptom.

VARICOSE VEINS AS DESCRIBED BY HALY ABBAS

DOUGLASS W. MONTGOMERY, M.D.
SAN FRANCISCO

Recently Paul Richter of Berlin has given a translation of the dermatologic portion of a treatise on medicine written in the tenth century after Christ by Āli ibn al-Ābbas commonly called Haly Abbas, a Persian who wrote in Arabic, the then dominant tongue.[1] The entire translation is most interesting and among other subjects includes a number of shrewd statements in regard to varicose veins and their associated diseases. Haly Abbas goes on to say, "Furthermore what appertains to both feet as elephantiasis, and the veins that are known as varicose veins, and the ulcer that is recognized as being peculiar to the city of Balkh."

Further along he practically repeats this statement with a slight extension:

"On both feet and on both legs there arises elephantiasis, the veins that are called varicose veins and the ulcer which is recognized as being peculiar to the city of Balkh. Elephantiasis is a black bile swelling that occurs on the legs and feet, and its symptom is that thereby the form of the foot is like that of an elephant's foot, and grows no thinner, like the shape of the body.

"Varicose veins are filling of the veins and their thickening, and they arise from a black bile mixture, which is poured into these veins and fills them, and they arise mostly in those who overwork their feet, and stand long on them, and through prolonged work of the body. In this way the mixture sinks into the veins that are in the legs, and therefore this happens mostly in peasants, porters and sailors, and the symptom of this disease is that these veins become tortuous and thick, and incline to be green or black in color, even if only slightly so.

"The ulcer peculiar to the city of Balkh arises on the leg, and its symptom is that it is an ulcer the place of which is circular and round, and that it tears up by destructiveness whatever is round about, and its healing is difficult.

"Of that that occurs on the hands and feet, the Medina-vein occurs on the leg and on the joints of the hands, and at times, in boys, in the groins, but rarely. Generally this disease occurs in hot countries, as in India, Egypt, and Abyssinia, and it is a disease that arises under the skin like a vein, and distinctly moves, as worms move, and if the place of the head of this vein opens, pains ensue."

Paul Richter said that the "medina vein" is the disease caused by the filaria medinensia. Balkh ulcer is ulcer of the leg, called after the city of Balkh in Bactria, modern Afghanistan; but why it is so called is a mystery.

Elephantiasis is elephantiasis Arabum, pachydermia, and not elephantiasis Graecorum, which is leprosy.

The Arabic name of varicose vein, dawali, a vine, is in itself beautifully descriptive. Furthermore, when we reflect that Haly Abbas was able to associate elephantiasis and ulcer of the leg with varicose veins, and in addition knew that varicose veins occur mostly in working people and those who stand at their work, and all this with no knowledge of the circulation, we must give him credit for knowing something of his subject from a purely clinical point of view. He was also aware that varicose ulcers are circular in shape, that they occur on the legs, that they sometimes spread with explosive rapidity, causing the tissues to melt down before their advance, and that they heal very slowly.

---

[1] Richter, Paul: Arch. f. Dermat. u. Syph., cxiii.

Haly Abbas does not mention the occurrence of ulcer of the leg or varicose veins in women, although in a modern American or European practice, among the well-to-do, many more women are seen with these affections than men, because of their dependence on the tumor of pregnancy. The reason for the omission probably was that Mohammedan women, then, as now, were supposed to have no souls, and their bodies were prized accordingly, and furthermore in a harem land it is improbable that Haly ever saw an ulcer or a varicose vein in a woman.

Not alone does Haly Abbas not mention the occurrence of varicose veins in women, but he makes no mention of treatment, excepting that ulcer of the leg heals with great difficulty. It must be borne in mind that he lacked all knowledge of the venous circulation, a knowledge that now forms the keynote of all our care of this condition.

This capital disadvantage in the ability to treat this condition, together with the poverty of the male patients who were afflicted with varicose veins and ulcer of the leg, would deter such a man as Haly Abbas from giving them attention, as neither honor nor fee would be his reward. In fact, it would be an anachronism to imagine such a "swell," whose very name, Ali, means sublime, attending at all to the ailments of lowly creatures such as slaves and women. It must be remembered that the prosperous workingman, who often nowadays gets far better attention than the very rich, is a modern invention.

Treatment, however, may have been the farthest from the thoughts of the Arabian scholar in writing a treatise on medicine. We are so used to looking on medicine from the point of view of treatment that it is difficult for us to regard symptoms as being employed exclusively to elucidate theoretical or ethical points, but it is possible that the study of medicine for this scholar of the tenth century was almost entirely abstract or academic. He makes one minute clinical observation that might lead to suppose this to be a fact. He says that "the veins are green or black in color even if only slightly so." Previously to reading Paul Richter's translation, I had paid no attention to the color of varicose veins further than that they had a deep, dark tone especially when large and tortuous, and this all seemed so natural as a consequence of the excessive saturation of the blood with carbon dioxid, as not to be worth remarking. The veins have a green tint also, occasioned by the blue color shining through the yellow epithelial layers of the skin, and as this yellowness becomes more marked with advance in years, the consequent green tint is particularly well seen in a disease of middle or elderly life like varicose veins. Haly undoubtedly ascribed these colors to the presence of his favorite black bile. He knew that bile was dark or green, just as he knew that it was yellow, and was likely only interested in varicose veins because they showed the dark blue and the green particularly well. He also probably knew of the connection of the hepatic vein with the inferior vena cava, and he thought that the bile was simply poured out of the liver through this channel and sank down into the lower extremities. This is interesting as showing how acute observation may be, directly that facts are sought to substantiate a belief, and this belief in the humors of the body was probably elevated in him into a sort of learned cult or religion. In all ages, human beings see what they desire to see, and according to their favorite theories.

Like his predecessors, the Greeks, Haly was a humoralist, and therefore ascribed almost all diseases to a faulty mixture of the humors of the body. Itchy and scaly diseases, for instance, were held to be caused by a mixture of the phlegm and the blood overloaded with gall. Other troubles were thought to be occasioned by the skin being too weak to get rid of the impurities of the body in people who ate bad food or food that gave rise to noxious juices, or in those who did not take warm baths. Haly speaks of the black bile, of the sharp yellow bile and the salty, phlegmatic mixture that mingles with the blood. He mentions the coarse, sticky phlegm that prevents the vapors from escaping. He also speaks of the good vapors. In fact, if Haly could be resurrected now, after ten centuries of life in the shades, he would not find so much difficulty in getting his clinical knowledge in touch with a modern laboratory worker. He would find that the bad vapor, carbon dioxid, and not the black bile, was the cause of the darkening of the veins, and he would quickly forget all about the green tint he had previously observed, and he would go away as elated as either you or I with this or any other explanation.

323 Geary Street.

NEGATIVE RESULTS WITH THE NINHYDRIN REACTION AS A TEST FOR AMINO-ACIDS IN THE SERUM OF NEPHRITICS AND OTHERS *

RICHARD M. PEARCE, M.D.
PHILADELPHIA

The use by Abderhalden of "ninhydrin" (triketohydrindenhydrate) as an indicator in his test for pregnancy, and especially his experimental work with Lampe,[1] in which ninhydrin was used to demonstrate amino-acids and related bodies in the serum, suggested the possible application of the test to the serum of persons suffering from nephritis, the intoxications of pregnancy and other conditions characterized by so-called nitrogen retention. Although our knowledge of the minute amounts of amino-acids in the serum and Abderhalden's statement that ninhydrin fails to react with an amino-acid (Glycocoll) when the dilution is greater than 1 : 11,000 presaged failure, it was deemed advisable to give the test a trial, especially as the labor of the procedure could be greatly lessened by using serum filtrates prepared in connection with other work[2] going on in the laboratory at the same time. Serums were obtained chiefly from nephritics and pregnant women—a total of 47 serums—in the hope that occasionally one with severe intoxication might yield positive results. The first group included acute and chronic nephritis with and without edema, uremia or high blood-pressure; the second, normal pregnancy, eclampsia and vomiting of pregnancy. Positive results were not obtained. In every instance in which coagulable protein was entirely

removed the test was, as one would expect it to be, negative.

The technic was to remove the coagulable protein in 10 c.c. of serum by the method of Folin (absolute methyl alcohol and zinc chlorid), evaporate the filtrate to dryness and take up the residue in distilled water. This filtrate was then made faintly acid with acetic acid and boiled and filtered to remove any trace of coagulable protein. To the resulting filtrate, after neutralization, was applied the ninhydrin test as used by Abderhalden, that is, to 10 c.c. of filtrate, 0.2 c.c. of a 1 per cent. watery solution of ninhydrin was added and the mixture boiled for one minute.

A few tests were made also with ascitic fluid, but with like negative results.

In connection with this report of negative results, the usual apology is offered; it may save someone unnecessary labor.

PASSAGE THROUGH GASTRO-ENTERIC TRACT OF BLACK-HEADED PIN, WITHOUT SYMPTOM

P. J. MANGAN, M.D., WINNEMUCCA, NEV.

Elizabeth M., aged 3 years and 10 months, swallowed a black-headed pin. I was consulted two days later. There being no untoward symptom, pultaceous food was advised, and close watch was kept of the stools. On the ninth day following its entry by the mouth, the pin, measuring 40 mm. in length, and lightly coated with mucus over the sharp end, passed by the anus. No inconvenience was experienced at the time and there has been none since.

HEPATIC ABSCESS (NON-AMEBIC) AND GASTRO-INTESTINAL MYIASIS

GLENN I. JONES, M.D., LUDLOW BARRACKS, MINDANAO, P. I.
Lieutenant, Medical Corps, U. S. Army

History.—The patient, Private P., was a soldier, aged 24. Family and previous history were negative, so far as referable to present illness. After several months' field service in Jolo, P. I., the patient was admitted to hospital at Augur Barracks, Jolo, P. I. Several days after admission he was transferred with his company to Ludlow Barracks, P. I., where he first came to my attention, April 5, 1913. Examination indicated tropical hepatic abscess, right lobe. Blood was positive for *Plasmodium falciparum.*

Treatment and Course.—The condition of this patient at the first examination (April 6, 1913) was critical; hence operation was postponed. Intramuscular injections of quinin were administered daily for two weeks. The patient improved slightly under quinin. Prostration increased, however, because of anorexia and hyperemesis.

Operation and Result.—After several days of rectal nourishment and stimulation, the patient was operated on, April 18, 1913, with evacuation of pus from right lobe of liver and perihepatic tissues. Postoperative progress showed improvement for several days and the temperature became normal, but gastric irritation persisted despite proctoclysis and rectal alimentation. The wound was closed (except for drainage sinus) April 23, 1913. April 24, 1913, the wound was reopened through the sinus and the right hepatic area was explored.

While the patient was under primary anesthesia, gastric lavage was practiced with a view to amelioration of hiccup and anorexia. The return contained between twenty and thirty living larvae of *Musca domestica.* The patient died April 25, 1913.

Necropsy.—Larvae were absent in the stomach, although the gastric mucosa was hyperemic and studded with hemorrhagic erosions. The entire right lobe of the liver had been destroyed and the cavity contained pus negative for entameba. Repeated examinations of feces during life had been negative for entameba. Perigastric and perihepatic recently formed adhesions were found at necropsy. No larvae were found in tissues or organs.

Inquiry as to camp conditions while the company to which this man belonged was at Jolo shows that flies were a pest and an anti-fly campaign had been inaugurated.

A case of intestinal myiasis was accidentally encountered at this hospital prior to observation of the case reported. The patient complained of attacks of pain resembling enteralgia (without febrile reaction) at irregular intervals. Attacks seemed not to have been influenced by dietary indiscretions. The larvae were finally observed grossly in freshly passed feces. Dietetic treatment and intestinal antiseptics by mouth and by rectal irrigation have apparently destroyed and evacuated all larvae. Periodic attacks have disappeared and no larvae have since been passed in the feces.

Therapeutics

TYPHOID FEVER

It is not necessary to mention that typhoid-fever bacilli enter the body by the gastro-intestinal tract, except to reiterate the many times repeated caution against uncooked infected food, milk, water or other beverage, contamination of these substances by flies (which may be carriers of these germs), and even against cleaning the teeth or bathing with infected water. Vegetables that are not to be cooked, such as lettuce, celery and radishes, may be infected by washing in impure water. Many of these latter sources of infection are readily forgotten or overlooked. Doubtless a certain number of these bacilli entering a perfectly healthy stomach may be there killed, but if the gastric juice is not in perfect condition, or if protective surroundings of the bacilli have prevented the gastric juice causing their death, or if large numbers are taken, they will reach the intestine. They here find in the alkaline half-digested food splendid mediums for their growth.

It is stated that these bacilli produce a toxin which more or less irritates and perhaps injures the mucous membrane of portions of the intestine, such injury allowing more readily the bacilli to enter the solitary glands and Peyer's patches. Sooner or later these bacilli reach the blood-stream through the lymph channels and may be there found, showing that typhoid fever is a bacillemia. The result, besides the local injuries and inflammation in the intestines, is a more or less high, continued fever, an enlarged spleen, more or less toxemia from the soluble toxins produced, more or less symptoms from putrefactive conditions that occur in the intestine, and one or more of the various complications that can occur from this serious disease.

PROPHYLAXIS

One of the greatest national sanitary questions to-day is the prevention of typhoid fever. Typhoid fever does not occur except by the carelessness of someone, or by the omission of some precautionary measures by someone. Every typhoid patient is a danger, not merely until he has recovered, but until he is not a carrier of typhoid bacilli.

It is not necessary here to repeat again the sanitary and hygienic rules and regulations for the personal care of a typhoid patient, which are generally well understood by physicians and nurses. The fresh air and sunlight that he needs, the absolute cleanliness, the care of the bed-clothing, the proper care of the excreta, even bronchial, mouth and nasal mucus, the screening from flies, etc., are all well understood; but the patient is allowed to convalesce completely and to go back to his active life, or at least to mingle with others, without establishing the fact that his intestinal canal and the urine are free from typhoid bacilli. Bacteriologic tests should certainly be made to show that a typhoid convalescent is not a source of danger to others.

Under prophylaxis must now be classed the prevention of typhoid fever by inoculation with dead typhoid bacilli. Such prevention has now well passed the experimental stage, and it is a fact that these injections of dead typhoid bacilli will and do prevent typhoid fever, and many boards of health will furnish these vaccines free for use on patients who are unable to pay the small fee charged for them. All young physicians, nurses, orderlies, boys and girls who leave home for seminaries or colleges, or any one who intends to travel where it is impossible to guarantee that every drop of water used or taken, or that the milk or food may not be contaminated with typhoid bacilli, should receive the preventive inoculations.

There seems to be less tendency to acquire this disease after 45 or 50 years of age, but all persons who are more or less constantly exposed to typhoid fever and who have not had the disease should certainly seriously consider the advisability of preventive inoculations.

To protect against typhoid fever three inoculations seem to be needed. The first dose should contain about 500 million dead bacteria, and in ten days a second injection should be given of about 1,000 million dead bacteria, and in another ten days the last and third injection of another 1,000 million killed bacilli should be given. Ordinarily the reaction is not great. While injections are often given to patients who continue their work, it would seem at least advisable to give the injection early in the evening, that the patient may rest for twelve or fifteen hours, and longer if there is a fever reaction.

It has been urged that with the typhoid injection dead paratyphoid bacilli should also be administered, as probably many times with the typhoid bacilli are also associated paratyphoid germs. As there are known to us at present, however, several types of paratyphoid bacilli it seems hardly advisable to recommend such injections for the present.

SPECIFIC TREATMENT

First, as to the vaccine treatment of the disease, there seems to be a growing belief that vaccination will hasten a slow recovery and prevent relapses during the fever. Also, it seems to be the proper treatment, and almost the only satisfactory treatment for typhoid carriers; and perhaps it will be wise to give such vaccinations after apparent recovery from typhoid fever even if there are no typhoid bacilli demonstrable in the feces or in the urine, on account of the possibility of such bacilli being lodged in the gall-bladder or elsewhere.

Vaccination has also been done during the acute fever, but, many times reported, without any apparent advantage. On the other hand, Dr. B. M. Randolph[1] of Washington, D. C., has treated a few cases by vaccination and thinks that he has positively seen improvement. He thinks that severe cases of typhoid fever have been modified to mild ones. The vaccine treatment of the acute stages of typhoid fever, however, is still experimental.

Up to the present time there certainly is no specific treatment for typhoid fever. Ipecac has been advised by some clinicians as being of value, much like its action in dysentery. It has been given in good-sized doses, in salol-coated capsules to prevent the irritation of the stomach and consequent nausea and vomiting. The ipecac treatment, however, has not many followers.

DIET

The diet in typhoid fever is excessively important. The many investigations into diarrheas, especially in children, has demonstrated how much the bacteria of the intestine may be changed by variations in the food. On any one kind of diet the bacteria of the intestines, or intestinal flora, remain about the same during health. If this diet is changed for another, for instance from carbohydrate to protein, the flora change. In brief, it has been shown that a diet of carbohydrates favors the growth of a certain kind of bacteria, which, however, bring forth more or less non-toxic products which inhibit their own growth. A protein diet, on the other hand, allows bacteria to develop and fermentation to occur, and products are absorbed that are more or less toxic to the economy, especially if the bowels are not thoroughly moved, and the membrane of the intestines is in such a condition as more readily to absorb toxins than normal, which conditions are present in typhoid fever. A diet that allows such fermentation and putrefaction to occur readily, causes a secondary toxemia, to say nothing of high temperature, entirely separate from the poisons and the disease of typhoid fever. Sugar has been shown to prevent, to some extent, the decomposition of protein[2] and lactose seems to be a good sugar for this purpose.

The diet of a typhoid patient should be mixed, containing carbohydrates in good amount, protein in small amount, and considerable sugar. The old milk diet does not fulfil these requirements. It has been now for several years thoroughly demonstrated that the typhoid patient should not be starved, as he does better on a liberal diet, unless there is some serious complication.

If the temperature is very high and the patient is decidedly toxic, the digestive fluids, especially of the stomach, are doubtless impaired; but in ordinary typhoid fever the digestion is probably not much impaired and intestinal absorption is good, and the appetite of the patient, though diminished from normal, will be sufficient, provided that he is not fed on one continuous food. It was the continuous milk diet that caused loss of appetite, heavily coated tongue, fermentation, flatulence and tympanites. Of course, if any particular article of food suggested is found to cause gastric or intestinal disturbance, this should be eliminated from the diet of this particular patient and some other nutritive substituted, but a diet properly varied with carbohydrate foods in the largest proportion (which foods protect the fat and even muscles of the body from waste), with a definite daily amount of protein, fat, sugar, salt and iron, if meat is not given, should prevent great emaciation of the typhoid patient. The aim, then, is to see that the patient receives every element of nutrition that he requires, that he has just sufficient protein to keep up a nitrogen equilibrium, and that he has enough starch to save his fat from destruction.

It has been asserted, and it is probably true, that if a large amount of fat is destroyed in the body, fatty acids of course occur, and later such toxic acids as diacetic and beta-oxybutyric and also acetone products, and this may produce the final toxemia that carries off the typhoid patient. In fact, this associated condition which we term acidemia probably occurs much more frequently in our seriously ill patients than we have supposed, and it is

2. Kendall, A. I.: The Journal A. M. A., April 15, 1911, p. 1084.

especially likely to occur when patients are long deprived of carbohydrates. On the other hand, nothing from the preceding should be thought to indicate that a typhoid patient should be deprived of protein. He must have protein to keep his nitrogenous equilibrium and to build up his own antitoxins and blood-ability to fight his infection.

Suggestions for the actual diet of typhoid fever are: Proteins: milk, eggs, meat-juice, beef tea, mutton broth; carbohydrates: oatmeal or other cereal gruel, barley-water, toast, various crackers and sugar of milk. Malted milk and ice-cream are both valuable protein and carbohydrate foods. Other valuable nutritives for the typhoid patient are butter, cream, gelatin, oranges and lemons. Other necessities are sodium chlorid, iron and water. Coffee and alcohol often give valuable nutritive aid.

A pint is sufficient milk for an adult. More is likely to cause indigestion, and there is nothing, perhaps, more likely to promote intestinal indigestion, with the formation of indigestible curds, and, therefore, to produce the best possible decomposing menstruum for the growth of intestinal pathogenic germs. Hence milk should not be pushed.

The various methods of administering milk should be considered. It may be hot or cold, with or without salt, with or without Vichy, or with or without lime-water, as deemed best in the individual instance. Kumiss or other soured milk may be considered; in fact, it may be good treatment to give an artificially soured milk two or three times a day for the benefit it is supposed to cause in the intestinal canal in preventing fermentation.

Yeast makes an acceptable sour drink for a fever patient. It cleanses the tongue, acts as a laxative, and is generally well borne. At the same time it changes more or less of the intestinal flora. A simple way to administer it is to dissolve about one-sixth of an ordinary compressed yeast-cake in three-fourths of a glass of water. This amount may be given once, twice or three times a day, depending on its acceptability to the patient and the way it acts on the bowels.

Sometimes buttermilk is used. This, when used, should be given in larger quantities than ordinary milk, and does not contain many of the elements that are undesired in pure milk.

Of eggs, two a day, or the whites of three, are sufficient. The eggs may be given raw, in a small eggnog, with sherry, or well beaten up and on cracked ice and lemon-juice, or as a cup custard, or poached.

Of course, it should be emphasized that the height of the temperature and the condition of the stomach and the cerebral condition all modify the character and the amount of the food which should be administered; but the temperature being ordinary and the brain clear, and there being no nausea or vomiting, semisolid foods will be as well digested as more liquid foods. Ice-cream or malted milk may be substituted for any one or more feedings of milk.

A typical good meat-juice is made by taking a pound of chopped round steak, covering it with water, allowing it to stand for an hour, and then expressing out all of this water, blood and serum by the aid of a meat-squeezer This is then placed in an ice-box and administered, properly salted, in two portions. This furnishes the best possible nutrition from beef-juice. Beef teas are not so valuable, although they may be used. The same is true of mutton broth; to this rice may be added, if all is thoroughly cooked.

If it is deemed best not to give meat in any form, iron must be given to the typhoid patient, and the best method is the *Eisenzucker*, saccharated oxid of iron, and a 3-grain tablet once or twice a day, crushed with the teeth or given in powder, is sufficient for all of the iron needs of the body.

Thoroughly cooked, thin oatmeal gruel is perhaps the best carbohydrate that can be offered; it should be properly salted. Any other simple cereal that is well cooked and is better liked by the patient may be used in its place. At least one cup of such cereal should be taken daily, with the addition of some other cereal during the day, perhaps at least two other feedings. If the patient is able to chew (and this should be encouraged for cleanliness of the teeth and cleaning of the mouth and tongue), some dry toast or even buttered toast may be given, or one or other of the many fine crackers that are offered, such as oatmeal crackers or other forms.

While we are urging that plenty of water be drunk, either plain, carbonated or as Vichy, or as an orangeade or lemonade, perhaps the blandest water we can offer is barley-water. This offers a bland, watery drink with the addition of a small amount of carbohydrate. The flat taste may be removed either by a little salt or a little lemon-juice, as desired. Sometimes an occasional cup of pure, clean clam broth is very acceptable to the patient.

As suggested, the patient needs some form of fat, and a little cream on bread, crackers or gelatin, or butter, should be given him, if possible. Perhaps no method is better than a little buttered toasted bread.

It must not be forgotten that the patient must receive sodium chlorid with some of his foods. When the old milk diet of typhoid fever was carried out salt was forgotten. He cannot make his hydrochloric acid without sodium chlorid.

If we believe in the theory that gelatin tends to make the blood more coagulable and prevent oozing of blood from inflamed membranes (of course neither gelatin nor any other coagulant could possibly prevent bleeding from an eroded blood-vessel), lemon, orange, brandy or sherry jelly made from gelatin makes an acceptable dish to be offered once or twice a day to a typhoid patient, especially after the first week.

The patient should have some fruit salts; orange-juice or lemon-juice presents these salts in a very acceptable manner, and a little each day should be given.

A patient who is used to coffee should have it in the morning, perhaps best without milk, and generally with sugar. This stimulation might be repeated during the day if advisable, but it should be remembered that coffee is a cerebral stimulant and it should never be given later than the noon hour if it is desired that the patient sleep during the night.

There is no excuse for the administration of alcohol to a typhoid patient as a stimulant, which it is not. On the other hand, if a patient is so ill that he can take but a very small amount of nourishment, alcohol will aid in giving him some nutrition. The best form is probably good whisky, and the outside limit should be not more than a teaspoonful once in three hours. It is a food and will protect some of the fat of the body, and may prevent in this manner toxic acidemias. A patient who was an alcoholic before his attack of typhoid fever might need more than this dosage.

The patient should be fed about every three hours during the daytime, the changes being varied from one nutriment to another throughout the day so that he does not become sickened of any one of them. During the night the intervals should be four or even five hours, if the patient is not very sick.

DIET, DUCTLESS GLANDS AND TUMORS

In commenting on the relation of nutrition to the growth of transmissible tumors[1] we referred in some detail to the recent investigations of Sweet, Corson-White and Saxon[2] in Philadelphia. They concluded from their experiments that: (1) the susceptibility of rats and mice to the transplantable tumors may be influenced both positively and negatively by proper diets; (2) the rate of growth of the transplanted tumors can similarly be influenced; (3) castration of the male renders the animal more receptive to the transplant, and the rate of growth of the tumor is increased.

Several years ago Hunt[3] described the influence of certain drugs and diets on the activity of the thyroid glands. Some of the substances were believed to stimulate, others to repress the gland functions. Reasoning that the influence of diet may be exerted through the ductless glands, the Philadelphia investigators attempted tumor transplantations in animals kept on the special diets intended to affect the thyroid. Here, too, as with the Mendel-Osborne diets, the development of the tumors was decidedly modified. Furthermore, the ductless glands were taken into consideration even more directly by transplanting tumors into animals deprived of certain possibilities in the nature of internal secretion by castration. Here it appeared that the removal of the testes in some way renders the animal a more receptive host, as seen by the increased "takes" of the tumors and their more rapid growth.

As a tentative hypothesis to correlate all of these conclusions, which seem justified by their experimental evidence, Sweet, Corson-White and Saxon suggest that perhaps special diets exert their specific influence on tumor growth through the intermediation of the ductless glands. Some of their comments in connection with the field opened by their studies are worth recalling here, since these reflect facts of clinical experience. We are reminded, for instance, of the relation of the thyroid to growth, as seen in cretinism; of the relation of the pituitary to acromegaly and gigantism and of the control of the pituitary over the only pronounced instance of embryonic cell production which persists in adult life, spermatogenesis and oogenesis. Finally, it is a clinical fact that cancer, notwithstanding many exceptions, is a disease of the menopause, that period of life when certain of the ductless glands lose their normal function, this loss entailing related changes in the whole chain of interrelated functions of the ductless glands.

It is dangerous and unprofitable to venture at present on the debated ground of the parasitic nature of cancer. If it shall appear further that the development of a neoplasm is directly influenced by conditions which modify normal growth, it will be difficult then to assume —so we are reminded by Sweet and his colleagues—that a parasitic process would obey the laws of normal growth.

THE WATER-SUPPLY OF RURAL COMMUNITIES

The emphasis of responsibility for the occurrence of water-borne diseases is so often put on the water-supplies of our larger communities that by way of contrast the conditions in American rural districts are usually thought of, if not actually pictured in the public mind, as almost ideal. Naturally enough, farms which are generally remote from villages and cities or other areas of congested population seem to be ideally situated for obtaining wholesome water. In reality, however, deplorably insanitary conditions as regards the farm water-supplies prevail widely, if we may believe the authorized reports that have accumulated within two or three years from various state and national government sources.

A large proportion of farm water-supply in the less hilly portions of the country where springs are not abundant comes from shallow wells, which are particularly subject to contamination. Deep wells are safer, but are not entirely free from danger of pollution. The chemist of the Canada Experimental Farms, Dr. Frank T. Shutt,[1] concludes from an examination of several thousand samples of water used on farm homesteads in Canada that "probably not more than one-third of them are pure and wholesome." According to the office of Experiment Stations,[2] investigations made by K. F. Kellerman and H. A. Whittaker of the Bureau of Plant Industry, in cooperation with the Minnesota State Board of Health, showed that of seventy-nine carefully selected and typical farm water-supplies in Minnesota, mainly well-waters, twenty were good and fifty-nine were polluted, usually because of careless or ignorant management, and generally as a result of poor location or lack of protection against surface wash or infiltration. The rivers, surface reservoirs and cisterns investigated were found to be polluted to such an extent that it is considered doubtful whether satisfactory supplies can be secured for household use from such sources. In an examination of the rural water-supplies in Indiana it has been found that "of the private rural water-supplies examined, 177 were deep wells, 411 shallow wells, five ponds, forty springs, and twenty-seven cisterns. One hundred and sixteen of the deep-well waters were of a good quality, forty-five were bad and sixteen doubtful. But 159 of the 411 shallow-well waters were potable, 209 were unequivocably bad, and forty-three were of doubtful quality." A large percentage of the waters used by the families in which typhoid fever had occurred was unequivocably bad.

[2] Kellerman, K. F., and Whittaker, H. A.: Exper. Sta. Work, 1913, xxvi, 5.

With the development of the country, the growth of the population and the greater congestion in living centers, the danger of pollution of natural water-supplies is vastly increased. Even wells can be improved and rendered less subject to pollution if proper methods of driving them deeper are employed. The best safeguard is the inculcation of the underlying facts of contamination so that by the application of common sense the sources of danger can be avoided by property-holders and others.

ABDERHALDEN'S TEST IN CANCER

The great need for a ready means of diagnosis of cancer, especially in its earliest stages, has led to the trial of various so-called serum tests, but so far not one of the various methods that has been proposed for this purpose has been found worthy of general confidence. Everything is still in the experimental stage. The latest proposal in this direction is Abderhalden's test, concerning the use of which in other conditions much is being written nowadays. This test is based on the consideration that when foreign proteins get into the blood, the body reacts by elaborating a ferment which causes their disintegration. The same reaction is believed to occur under the influence of certain peculiar protein substances derived from the organism itself. As elements from the placenta pass into the maternal blood, the serum acquires the power to digest placental tissue. This power is believed to be present only in pregnancy, and Abderhalden's test for pregnancy is based on this principle.

May it not be possible that in cancer analogous reactions occur so that the serum of cancerous patients may be able to digest cancerous tissue? If this should be the case, the detection of the products of such digestion would be a means of specific diagnosis. The method is simply this: A small piece of cancerous tissue is placed in a dialyzing-sack and covered with a few cubic centimeters of the serum of the suspected cancer patient; this sack is put in a 2 per cent. solution of sodium fluorid in a suitable container and the whole placed at 22 C. (71.6 F.) for thirty-six hours. At the end of this time the fluid outside of the dialyzer is tested for products of protein digestion. The presence of peptones signifies a positive result—the patient has cancer. It is absolutely necessary for perfect sterility to be maintained throughout, as contamination spoils the result.

Among many others working in this line, Erpicum[1] tested the serum of forty-two patients with tumors in various parts, the exact nature of which was determined later after operation. Of these tumors all the cancers (two sarcomas) gave positive results. The benign tumors gave negative results. This outcome certainly is impressive, almost too good to be true, but if confirmed by more extended observations a great advance will have been made in the struggle against cancer.

THE TRANSPORT OF PARTICLES FROM TISSUE SPACES

The question of whether and, if so, how undissolved particles can traverse the walls of the blood-vessels and lymph-vessels has vexed physiologists for more than a generation. So long as it was assumed that the lymph-vessels take their origin in the tissue spaces or the unbounded interstices of the connective tissues, the possibility of a channel of exit for minute suspended particles as well as for solutions was always left open. But when the histologist began to demonstrate that the tissue spaces are in truth closed regions limited by a special endothelial wall, the sole refuge for the escape of solid particles seemed to lie in the alleged stomata or peculiar perforating openings which were assumed to afford a convenient outlet, even to formed elements. The day of the stomata from which so much was expected has come and gone, while the problem of the removal of undissolved substances from the subcutaneous and other lymph-spaces remains.

It seems to be demonstrated by convincing researches, particularly those of Mills and Murlin,[2] that fat, a substance insoluble in either the lymph or the blood, can actually find its way from subcutaneous tissue spaces, into which it may be introduced by hypodermic injection, to the blood-stream. Several possibilities suggest themselves in explanation of the transportation of fat. The substance may be converted into soluble compounds through the agency of lipolytic enzymes in the tissue spaces or fluids, that is, digested *in situ*. It may become thoroughly emulsified and travel engulfed by leukocyte-like cells which wander from one spot to another in the organism. Or finally, the minute fat particles in suspension may even be conceived to penetrate as such the vessel-walls when the insoluble substances introduced are in a state of extremely small subdivision.

Obviously the possibilities open to indigestible insoluble particles such as colloidal suspensions of metals, pigments, lipoids, etc., are even less favorable than in the case of fats, in which at least some digestive transformation is always conceivable. Investigations of Dr. Alfred Neumann[3] in Vienna with suspensions of diverse substances such as colloidal silver, casein, sudan, oleic acid, butter, lecithin and lanolin, have failed to demonstrate any transference of these corpuscular particles from the meshwork of the subcutaneous tissues, into which they were cautiously introduced, to the lymph-stream or blood-current. Since this is a substantiation of what others have found by the aid of less refined technic, one can only conclude that the subcutaneous tissue acts as a sort of filter mesh which permits solutions but not suspended matters to penetrate it. In view of these observations one is in turn forced to the conclusion that in the case of the fats, which are actually known to enter the circulation from the seat of their injection, there must either be a conversion into some subtle modification or an active participation of transporting phagocytic cells in carrying the foreign product from the site of its introduction to distant places in the body.

NAUSEA

Although pain has always attracted due consideration in the domain of medicine, there are other sensations which have scarcely received the attention which a careful analysis may show that they merit. It has happened, therefore, that such subjective symptoms as hunger and appetite, satiety and nausea, rarely play any practical part in the management of the cases that come to the notice of the physician for treatment. This is largely accounted for by the fact that the phenomena of these more obscure sensations are not amenable to the same sort of interpretation or control as are the numerous other symptoms which have more objective manifestations. Usually they have been relegated to the care of the psychologist with little thought of further practical use.

The genesis of hunger has already been discussed in these columns.[1] The possibilities of the appetite as a factor in nutritive welfare, and the significance of conserving or awakening this sensation as an aid to dietotherapeutic measures, are beginning to receive some recognition, though not what their importance merits. If it is true that the intelligent and effective management of appetite has been neglected in the past, certainly the meaning of the sensation of nausea has hitherto been completely disregarded. Sternberg[2] has pointed out that it is a mistake to identify or confuse nausea with lack of appetite. He maintains that the cause of the undeniable demand for variety instead of monotony in diet is closely bound up with the physiology of nausea. Indeed, it is a rather remarkable phenomenon, when one stops to consider it, that the transition from appetite to indifference, from eagerness for food to complete anorexia, takes place at times with so little apparent reason for it. Let a slight surfeit of even some palatable food be ingested, and relish may promptly become converted into nausea.

The "failure" of the appetite has been attributed by some to a fatigue of the sense of taste. Yet this cannot well account for the positive manifestation of nausea which may follow it; for if lack of appetite be explained in ultimate analysis by the idea of lack or failure of taste, it must at most be merely a state of indifference. Nausea, however, is an active something, not a mere negative phase of appetite or satiety. The demand for a change of diet may be the response to incipient nausea; and Sternberg would have it that this sensation is centered in a vomiting or antideglutition reflex which may succeed the usual events of deglutition just as antiperistalsis follows the normal peristaltic sequences in lower portions of the alimentary tract. Nausea is the premonitory symptom of the act of vomiting. Attempts to thwart the sensation of nausea must be directed to its physiologic basis, the vomiting mechanism; and what will affect the other sensations already discussed need by no means have any influence on the one here under consideration.

The clinician will find appropriate occasion at times not merely to overcome the feeling of nausea, but even to awaken it. The timely development of this sensation is one of the means at his disposal in the treatment of obesity.[3] It is not difficult to destroy a patient's appetite. The success of the reduction treatments—not "cures" as they are so often erroneously translated from the German—for obesity at various resorts, such as Marienbad, is in part attributable to the fact that they obliterate the appetite. But therapeutically this anorexia can even be carried to the extreme of incipient nausea. Such *Ekelkuren* are said to have been popular on the European Continent at one time, though they are scarcely heard of to-day. It is only necessary to administer minimal doses of emetics to accomplish what is aimed at by nausea in reducing the desire for food, with a consequent loss of body-weight. Indeed, in some persons an inordinate intake of tasteless fats as prescribed by some physicians in anti-obesity treatment amounts ultimately to the "nausea treatment." Other possibilities associated with the hitherto ill-defined sensations which we have referred to are likely to come to light and find useful applications when once the phenomena are given more rational consideration and scientific analysis.

Current Comment

A FOOD CLINIC

At the Congress on School Hygiene, held in Buffalo in August, Dr. Walter M. Roach, district supervisor of school medical inspectors in Philadelphia, reported the results obtained among schoolchildren of ages from 6 to 14 years after the establishment of a food clinic in certain schools in his district. Many of the children were found to be coming to school with insufficient or no breakfasts. The children were fed for a period of four weeks in the spring of 1913 at the morning recess period with some form of cereal and milk, the form of cereal being changed daily. In all, 113 children were fed in this manner. In a group of fifty, who were carefully weighed, measured and physically examined before the beginning of the feeding and afterward, it was found that there was an aggregate gain of over 252 pounds. But, as stated in the report, the increase in weight from a given amount of food in the time mentioned was not the chief advantage gained. Some of the children gained little or nothing in weight, but it was found that they all improved in color, increased in hemoglobin percentage, gained in spirits and activity, and were less nervous and irritable. They were able to study better and their work progressively increased in effectiveness, which was demonstrated by their grades. The average grades for the whole school, 350 pupils, including the 113 who were given the feedings, increased in spelling from 76.4 to 82.3, and in arithmetic from 69 to 72. For the same period the averages of the pupils of the second grade attending the clinics increased from 71 to 87 in spelling, and from 59.6 to 71.3 in arithmetic. In the third and fourth grades, as also in the special classes for retarded pupils, the improvements were equally notable. Aside from the demonstration in figures of the effect of adequate nourishment on the work of the pupils, another interesting deduction is made in the report. The per capita cost of education in the public schools in Philadelphia exclusive of permanent improvements is $36.59 per child per year. If the child fails to make its grades, it is a fair deduction that the $36.59 has been an economic loss, and whatever may be thought of the proposition of the school authorities going into the business of feeding the children in the schools, the author of the report feels that if an expenditure for food of $10 per pupil for two hundred school days would make the $36.59 productive, it could be considered as an economic gain; the outcome, he feels, "removes the problem from the sphere of paternalism."

THE STATE BOARD QUARTERLY

The first copy of the new *Quarterly*,[1] the official organ of the Federation of State Medical Boards of the United States, has just been received. It is published by the federation, the secretary being also the editor, and it is announced that "the *Quarterly* shall be the forum for the presentation and discussion of ideas on medical education by any one interested." The several articles from well-known writers on medical education and medical licensure are printed in large, clear type; there are numerous interesting excerpts from important articles on medical education, and the news notes show care in selection. This number also contains a list of members, reports of meetings and the constitution and by-laws of the federation. We bid the *Quarterly* welcome to the ranks of medical periodicals, and wish for it a most influential existence. Its greatest influence, however, will depend on whether or not it recognizes its chief function as an instrument for the exchange of information which state board members need. Much is already being published regarding medical education—all medical journals are naturally interested in that. But regarding the problems of medical licensure in this country, this publication has a particular and a most important field in which it can be a power for good. To point out the needs in medical licensure, to suggest remedies, to bring about a closer cooperation between state licensing boards and to secure a more equally effective administration of all medical practice acts—this is clearly the chief field of the new State Board *Quarterly.*

THE FOOD FACTOR IN SOME SOCIOLOGIC PROBLEMS

In connection with a consideration of the opportunities, or lack of opportunity, for adequate nutrition which prevail among the poorer classes in large cities,[1] it became apparent that there are in such communities not a few families which actually suffer from a lack of sufficient food. The main items of expenditure among the laboring classes are for food and rent. These are, of course, absolutely essential. It is interesting to note, therefore, from the statistics that have lately become available, how the percentage of income expended on rent and food increases as the income decreases. These stubborn facts enable us to realize the keenness of the struggle to make ends meet in poorer homes, even with a regular income, when it is very small. When over 90 per cent. of the wages earned is thus disbursed, the opportunity to obtain other necessities—not to mention non-essentials—is so limited that frequently recourse is had to a reduction in the food bill, which is already as low as is consistent with the maintenance of health. Here is a condition which perhaps permits the inroad of disease among the poor quite as readily as other unhygienic living conditions, particularly those pertaining to housing and environment. When there is even a moderate expenditure for alcohol the situation is even worse. Perhaps our sociologists have not sufficiently appreciated in the past that the occurrence of conditions in which the support of the family and the provision of even the barest necessities prevent the attainment of any variety and interest in life and almost enforce a monotonous existence reacts in a variety of ways on the health and efficiency of the community through the diet factors referred to. The essays at amelioration and reform must accordingly take into account possible changes in the mode of feeding which might set free a greater proportion of the income for other things than food. Dietary habits need to be dealt with in this field quite as much as ignorance and the "stultifying influence of the surroundings."

THE CONVENIENT AMERICAN MILLIONAIRE AND THE ADVERTISING QUACK

There seems to be no limit to the ingenuity of the quack and the semiquack in devising methods of advertising themselves. A new turn has been given to the game by a French physician, as recorded in the *Journal de médecine de Bordeaux*, the details of which are as follows: In the daily newspapers of Bordeaux an advertisement appeared to the effect that an American millionaire coming to Bordeaux desired to hear of a physician who could cure his tuberculous daughter and syphilitic son, for which information he would pay 100,000 francs. This, as may be supposed, created much interest in the neighborhood. The reputation of American millionaires for freely shedding their coin no doubt created visions of a golden shower much in excess of the paltry 100,000 *francs*. The secret and solution of the whole matter, however, were revealed a week later in a second advertisement of the supposed American millionaire in which he heartily thanked his numerous correspondents for naming the physician who could cure his tuberculous daughter and syphilitic son. It was none other than Dr. T—— of Bordeaux whom "almost all the letters received had recommended," and thereby the stock and credit of Dr. T—— in that community no doubt went floating skyward. The medical journal, in commenting on the clever advertising dodge of Dr. T——, commends his modesty in saying that "almost all the letters" recommended him, instead of claiming that he was the only one named. The cure by Dr. T—— of the mythical American millionaire's son and daughter of course has no relation to the point of this story.

EXUBERANT VERBOSITY

The medical profession is perennially accused of lack of clarity of expression in dealing with medical subjects. In the accusation there is a certain amount of justice, but the critics forget that many scientific subjects, especially those of a technical nature, cannot easily be dealt with in the language of the street. Nevertheless, the charge that we are not clear and direct in our method of expression makes us sad. That is, until we happen to get hold of a piece of *composition written* in legal phraseology. Then by comparison the most turbid of medical expressions become clear. These facts are suggested by reading a charge made by a grand jury against a physician who had rendered a bill against the county for more than was due him. Briefly, the doctor had claimed to vaccinate twenty-seven more persons than he actually had vaccinated, and thus obtained from the county twenty-seven dollars which did not belong to him. The misdemeanor was not an involved one but the grand jury stated it thus:

> John Doe, on the fourth day of March, in the year of our Lord one thousand nine hundred and twelve, in the county aforesaid, with force and arms did unlawfully, by using deceitful means, artful practices, defraud and cheat the County of ——— in the State of ——— out of the sum of $27. . . .

And as though this charge were not sufficiently overwhelming, the grand jury goes into details regarding this misdemeanor thus:

> The said John Doe then and there represented to said
> Board of Commissioners that he vaccinated the above-named
> persons and the said board then and there paid the said John
> Doe one dollar each for the above-named persons, and said
> payment was made upon said representation and said repre-
> sentation so made by the said Doe that he vaccinated
> the above-named persons was false, and made by the said
> Doe for the purpose of cheating and defrauding the said
> County of ——— and said Board of Commissioners of Roads
> and Revenues of said county, out of the sum of twenty-seven
> dollars, and because of said false representation said County
> of ——— was cheated and defrauded by the said John Doe
> out of said sum of money, contrary to the laws of said state,
> good order, peace and dignity thereof.

A noted English statesman, long since dead, once accused his political opponent on the floor of the House of Commons of being "intoxicated with the exuberance of his own verbosity." A study of legal phraseology leads the layman to wonder if this is not a species of intoxication indulged in by those who are submerged in an otherwise dry subject. If so, a new field of investigation may be opened up. A study of the pathology of the verbal "jag" might throw some light on this obscure subject.

THE BAD TASTE IN HYPOCHLORITE-TREATED WATER-SUPPLIES

It is surprising, as pointed out by Lederer,[1] that so little attention has been paid to the question of removing the taste from water-supplies treated with chlorinated lime. In this country especially, where the treatment of many large public supplies has been carried out with brilliant sanitary success, there has been frequent and often bitter complaint about the taste of the treated water. As well known, antagonism has developed in many places between water boards and health departments as a result of these conditions. On one side is the recognition that the danger from water-borne diseases is greatly reduced by the hypochlorite treatment: on the other is the necessity of having to bear the burden of daily complaint and to meet the indignant protests of thousands of aggrieved water-drinkers. As pointed out by Lederer, a simple method is available for removing the taste from hypochlorite-treated water. After careful experimenting he has confirmed the advantage of sodium thiosulphate ($Na_2S_2O_3,5H_2O$) as recommended by Bruns. The reaction on the residual chlorin is as follows: $Na_2S_2O_3 + 8Cl + 5H_2O = Na_2SO_4 + H_2SO_4 + 8HCl$. The acids formed in the neutralization process immediately combine with bases to form neutral salts. Lederer has obtained good results in the elimination of taste in Lake Michigan water treated in this way. Sodium thiosulphate seems to possess marked advantages over sodium sulphite. It must be remembered that the action of the thiosulphate stops the germicidal action of the chlorin so that it is necessary to allow the chlorin to act for a sufficient length of time (Lederer recommends from at least ten to fifteen minutes) before the thiosulphate is added. An interesting point brought out in the discussion of Lederer's paper is that hypochlorite seems under some conditions to accentuate an *unpleasant taste* originally present in the water. In Toledo, for instance, it is stated that the water develops a disagreeable taste when the river first freezes over, owing to the presence of large amounts of vegetable matter in the water. The bad taste is said to be increased by even *small amounts* of hypochlorite.

THE INFLUENCE OF THE BRAIN ON METABOLISM

We have, before this, discussed the question as to the expenditure of energy incidental to nervous work.[2] The nervous system forms, in quantity, so small a part of the total metabolically active tissues of the entire body that it is most difficult to detect small increments of energy transformation that might be due to nervous "work." Isolation experiments such as were referred to in a recent issue of The Journal[2] are difficult of performance with the sensitive nervous system. Even if, as seems to be the case, there is little evidence for any considerable direct utilization of energy in the performances of the nervous centers, this does not preclude the possibility of a very appreciable indirect influence on metabolism. That such can actually be realized is indicated by recent experiments in Tangl's laboratory in Budapest,[3] though the results are quite contrary to what one might expect at first thought. We are so accustomed to associate the nervous system with the initiation of impulses—with the awakening to activity and a physiologic goading to work—that it comes as a surprise to read of the reverse. Yet Hannemann has found that after the total extirpation of the brain there is a marked increase in the respiratory exchange and the heat production parallel thereto. This is apparently not due, as might be suspected, to the operative interference or to infectious processes ensuing, but is the outcome of a removal of inhibitory influences ordinarily exerted by the higher nervous centers. Extirpation of smaller areas may lead to similar results. The fact that these observations were made on lower animals does not detract from their general interest. They serve, if nothing more, to make us realize better the potent part which inhibition plays in physiologic manifestations. The central nervous system serves quite as useful a function in repressing and restraining the inherent tendency of a reflex organization to undue and continued activity as it does in keeping the machinery of the body in well-regulated operation.

Medical News

ILLINOIS

New Officers.—Fulton County Medical Society at Canton, October 7: president, Dr. Isaac L. Beatty, Fairview; secretary-treasurer, Dr. David S. Ray, Cuba.

Personal.—Dr. C. T. Roome has been appointed health commissioner of Evanston, succeeding Dr. Victor Balderston, resigned.——Dr. and Mrs. T. W. Curry, Streator, have returned from Europe.

Tag Day for Silver Cross.—Silver Cross Hospital, Joliet, has become too small for the needs of the city and an addition is proposed to cost $55.000. To accomplish this a tag day was held in Joliet October 11. The addition to the hospital will double its capacity.

Officers for State Anti-Tuberculosis Association.—At the annual meeting of the Illinois Association for the Prevention of Tuberculosis, held in Rockford, October 13, the following officers were elected: president, Dr. W. A. Evans, Chicago; vice-presidents, Dr. Tully O. Hardesty, Jacksonville, and Mrs. J. J. Robins, Chicago: secretary, James Minnick, and treasurer, David R. Forgan, Chicago.

Sanatorium Notes.—The ten-day campaign in Aurora, to raise $100.000 for St. Joseph's Sanatorium, was successful and work on the new buildings will be started in the early spring.——Dr. J. H. Steely, Freeport, has purchased the property of the National Sanatorium and Springs for $25,500.——Dr. Elbert W. Oliver, Peoria, has acquired 120 acres on the Tazewell County side of the Illinois River, and announces that he will build a sanatorium next spring, to cost $100,000.

Chicago

Personal.—Dr. E. H. Ochsner has been appointed a member of the state charities committee, succeeding Dr. Frank Billings. Dr. Anna Dwyer has also been appointed a member of the committee.

Commends McCormick.—The Chicago Surgical Society, at its meeting October 3, adopted a resolution commending Mr. A. H. McCormick, president of the Board of Commissioners of Cook County, for the work which has been done in Cook County Hospital toward putting the institution on a scientific basis.

Specialists Form Alumni Association.—The alumni of the Illinois Charitable Eye and Ear Infirmary, which since its establishment in 1858 has graduated less than seventy-five persons, have formed an association with the object of holding an annual meeting in the effort to differentiate them from many who make claim to be alumni of the infirmary, after having made only clinical visitations. An emblem has been selected, to be presented to each alumnus who completes his services in the institution.

INDIANA

Personal.—Dr. George W. Buckner, Evansville, has been appointed Minister to Liberia, and has started for his post of duty.——Dr. Fred A. Dennis, Crawfordsville, has been elected president of the Montgomery County Anti-Tuberculosis Society.——Drs. John F. Barnhill, John H. Oliver and David Ross, Indianapolis, have returned from Europe.

State Board to Be Transferred to University.—Governor Ralston has recommended to the State Board of Buildings and Properties that the State Board of Health, with all its laboratories, be transferred to the Indiana University School of Medicine buildings, west of the State House, provided the transfer can be made without too great expense.

County Tuberculosis Colonies.—The Richmond Commercial Club is cooperating with the members of the Wayne County Medical Society and the Wayne County Anti-Tuberculosis Society, for the establishment of a tuberculosis colony. The plan to establish a tuberculosis colony on the grounds of the Reid Memorial Hospital has been abandoned because the site is on or near marshy ground.——It is planned to establish a county tuberculosis sanatorium for Laporte County near LaPorte.

Physicians Win Suits.—Dr. Grant C. Markle, Winchester, secretary of the Randolph County Board of Health, has been awarded damages of $7,600 for injuries received when struck by a train on the Big Four Railroad in January last.——Dr. Arthur G. Tullar, New Carlisle, who sued the town for his services in the treatment of contagious diseases, has been awarded a verdict of $363.22. The court held that while Dr. Tullar was under contract to treat the sick of the town, this contract did not include contagious diseases.

State Association Meeting.—At the annual meeting of the Indiana State Medical Association, held in West Baden, September 24-26, the following officers were elected: president, Dr. James P. Salb, Jasper; vice-presidents, Drs. Charles E. Stone, Shoals; Porter H. Linthicum, Evansville, and Charles L. Botkin, Farmland; secretary, Dr. Charles N. Combs, Terre Haute; treasurer, Dr. David W. Stevenson, Richmond, and delegates to the American Medical Association—Drs. Edwin Walker, Evansville, and J. Rilus Eastman, Indianapolis. Lafayette was selected as the next place of meeting.

MARYLAND

Baltimore

Dr. Keirle Honored.—Dr. Nathaniel G. Keirle, city postmortem physician and chief of the Pasteur Institute at the College of Physicians and Surgeons, was tendered a banquet on Saturday evening, October 11. Arrangements for the banquet were made by Dr. Harry Friedenwald.

Appeal for Funds.—An appeal for funds has been made by the Board of Managers of the Home for Widows and Orphans of Physicians, of which the late Dr. Eugene F. Cordell was president. As this is the first home established in this country for such purpose, the managers are especially anxious to have it continue.

[3] Hannemann, K.: Zur Kenntnis des Einflusses des Grosshirns auf den Stoff- und Energieumsatz, Biochem. Ztschr., 1913, liii, 80.

MASSACHUSETTS

Ether Day.—The sixty-seventh anniversary of Ether Day was celebrated in the lower amphitheater of the outpatients' department of the Massachusetts General Hospital, October 16. The principal address was delivered by Dr. Milton J. Rosenau.

Warren Prize Awarded.—The Warren triennial prize for 1913, amounting to $500, has been awarded to Dr. Prof. Arrigo Visentini, instructor in pathologic anatomy in the Royal University, Pavia, Italy, for his essay entitled, "Function of the Pancreas and its Relation to the Pathogenesis of Diabetes."

Refused to Build Hospital.—The special committee on tuberculosis of the House of Representatives has called on the mayors and city governments of Medford and Attleboro to appear before it and explain why they have not complied with the law requiring cities and towns to establish and maintain tuberculosis hospitals and dispensaries.

Wesson Hospital Thrown Open.—Wesson Memorial Hospital, Springfield, by decision of the board of trustees, will be open for patients of any physician of the city after October 1, instead of being confined to patients of the members of the hospital medical staff. The institution has accommodation for seventy patients, but is only about half full at present.

Personal.—Dr. Theodore H. Aschman, Boston, has been appointed head of the anatomy department in the Harvard Medical School, Shanghai, and sailed from San Francisco for his new post of duty September 30.——Dr. Patrick F. Gahan has been appointed a trustee of the Medford Public Library.——Dr. Elliott Washburn, Taunton, has succeeded Dr. P. Challis Bartlett, resigned, as superintendent of the State Sanatorium for Tuberculosis, Rutland.——Dr. Victor V. Anderson, assistant instructor in psychology in Harvard University, has been appointed assistant probation officer of the municipal criminal court, Boston.——Dr. Charles A. Deland, Warren, has been appointed medical examiner of the ninth Worcester district, vice Dr. Ephraim W. Norwood, deceased, and Dr. James C. Austin, Spencer, has been appointed associate examiner.——Dr. P. Challis Bartlett, retiring superintendent of the State Sanatorium, Rutland, was given a farewell banquet at the Hotel Bartlett by the members of the staff of the institution September 17. Dr. Bartlett expects to enter private practice in Boston.——Drs. Edward and Simon J. Russell, Springfield, have returned from Europe.——Dr. Robert W. Hastings has been elected chief medical inspector of the public schools of Brookline, succeeding Dr. Lincoln Chase, resigned.

MISSOURI

Hospital for Negroes.—The negroes of Kansas City have undertaken the establishment of a hospital for the treatment of members of their own race, to cost about $30,000. The hospital is to be named "The Phyllis Wheatley Hospital."

Personal.—Dr. Thomas O. Klingner, Springfield, has been appointed councilor for the Twenty-Eighth District, succeeding the late Dr. A. H. Madry, Aurora.——The Board of Trustees of the Federal Surgeons' Home, St. James, has reappointed Dr. Charles H. Fulbright, surgeon of the home.——Dr. William J. Calvert, Columbia, has resigned as professor of preventive medicine in the University of Missouri, to accept the appointment of professor of practice of medicine in the Medical Department of Baylor University, Dallas, Texas.——Dr. Guy L. Noyes has been appointed acting dean of the School of Medicine of the University of Missouri, Columbia.——Drs. Hasbrouck De Lamater and George P. Pipkin have been placed in charge of the Kansas City Isolation Hospital.——Dr. Arthur M. Gregg, City Physician of Joplin, has gone to Kansas City to take the Pasteur treatment.——Dr. John M. Dunsmore, St. Joseph, was obliged to have his left eye enucleated, September 18, as a result of the explosion of a bottle.——Dr. Robert B. Middlebrook, Jr., night superintendent of the Kansas City General Hospital, has resigned.——Dr. F. G. Beard, St. Joseph, has been appointed assistant police surgeon, succeeding Dr. W. H. Litter, appointed assistant city physician.

St. Louis

Progress of the Sanatorium Fund.—The Board of Directors of the Missouri Baptist Sanitarium, say that $152,000 is already on hand for the building fund for the addition to the institution.

Hospital for Carondelet.—Work has been started on the Matilda Hospital, Carondelet. The building is to cost $20,000, and is intended to care for cases now sent to institutions at a distance from this suburb.

Personal.—Dr. Wayne Smith, for two years superintendent of the St. Louis City Hospital, has resigned to become general manager of the Harper Hospital, Detroit, Mich.——Dr. Frederick W. Veninga has been elected surgeon-general of the United Spanish-War Veterans.——Dr. Bradford Lewis has been elected an honorary member of the Kentucky State Medical Association.

New Faculty Members.—The St. Louis University School of Medicine announces the following faculty appointments: Dr. A. G. Pohlman, formerly professor of anatomy in the University of Indiana, professor of, and director in, the department of anatomy; Dr. Don R. Joseph, formerly associate professor of physiology in Bryn Mawr (Pa.) college, professor of, and director in, the department of physiology; Dr. Albert Kuntz, formerly director in the University of Iowa, Iowa City, assistant professor in experimental biology; and Dr. Hanau W. Loeb, dean of the medical school.

NEW MEXICO

New Board of Health.—The mayor of Albuquerque has appointed the following as a city board of health: Drs. J. A. Reidy, L. G. Rice and Harry B. Kauffmann, and Mrs. David Rosenwald.

Albuquerque Physicians Indicted.—Twenty-five physicians of Albuquerque were recently indicted by the Bernalillo County Grand Jury, charged with violating the statute which requires the filing of death certificates with the county clerk.

New Officers of State Society.—At the annual meeting of the New Mexico Medical Society, held in Albuquerque, October 3 and 4, the following officers were elected: president, Dr. H. B. Kauffmann, Albuquerque; vice-presidents, Drs. W. T. Joyner, Roswell, Evelyn Frisbie, Albuquerque, and William Howe, East Las Vegas; treasurer, Dr. F. E. Lull, Albuquerque; councilor, Dr. LeRoy Peters, Silver City; delegate to the American Medical Association, Dr. W. R. Tipton, East Las Vegas, and alternate, Dr. S. S. Swope, Deming. It was decided to hold the next meeting at Albuquerque.

NEW YORK

Work of Health Council.—The State Public Health Council met for organization in Albany, September 30, and the work laid out for it includes the drafting of a state-wide sanitary code and the formulation of qualifications for the candidates for the many new positions created by the organization act.

New Officers.—Medical Society of the State of New York, First District Branch, at Yonkers, October 9: president, Dr. Henry Lyle Winter, Cornwall; secretary, Dr. Charles E. Denison, New York City.——Ontario County Medical Society, 107th annual meeting at Canandaigua, October 7: president, Dr. Homer J. Knickerbocker, Geneva; secretary-treasurer, Dr. Daniel A. Eiseline, Shortsville (reelected for the seventeenth time).——Medical Society of the State of New York, Fifth District Branch at Oneida, October 2: president, Dr. Frederic H. Flaherty, Syracuse; secretary, Dr. J. F. McGaw, Watertown. Syracuse was selected as the next place of meeting.

New York City

Typhoid Fever Epidemic Continues.—Many new cases of typhoid fever continue to be reported in the southern and eastern portions of the city. There were 183 new cases reported for the week ended September 27, as against 42 cases for the corresponding week of last year. Dr. Lederle has expressed the opinion that the epidemic has reached its maximum and that a gradual decline may now be expected.

Personal.—Dr. Joseph A. Blake has resigned as a member of the faculty of the College of Physicians and Surgeons.——Dr. Lucius W. Hotchkiss suffered a fracture of the jaw, a dislocation of the right arm and a strain of the right leg by the overturning of his automobile at Parsippany, N. J., September 28.——Dr. Robert J. Morrison, Brooklyn, who has been seriously ill with septicemia, the result of an operation wound, is reported to be out of danger.——Dr. Emil Boehm is said to be seriously ill with septicemia, due to an operation wound.

OHIO

New Officers.—Muskingum County Medical Association: president, Dr. Wilbert C. Bateman; secretary, Dr. John R. McDowell, both of Zanesville.

Open-Air School Ready.—The Columbus Society for the Prevention and Cure of Tuberculosis opened an open-air school in Hudson Avenue, October 1.

New Society Organized.—Members of the medical profession of Tiffin, met on September 30, and organized the Academy of Medicine of Tiffin, with Dr. Harmon B. Gibbons, temporary chairman, and Dr. John A. Gosling, temporary secretary, and an initial membership of thirteen.

Rendezvous for Physicians.—Members of the Dayton Academy of Medicine are fostering a movement to secure a clubhouse and headquarters for physicians of the city, to be a common rendezvous for medical men of all schools, and to provide, in addition, a clinical laboratory.

Greene County Must Pay Its Share.—The supreme court has decided, in the joint county tuberculosis hospital case, that Greene County must pay its share of the cost of the hospital, which was built by Champaign, Clarke and Madison counties. This share amounts to $6,254.15

Personal.—Drs. Paul Morrison and D. W. Medill, Tiltonsville, who sustained injuries in an automobile accident, recently, are reported to be doing well.——Dr. R. DeWitt Robinson, Akron, was operated on for appendicitis at Grace Hospital, Cleveland, October 5.——The residence and office of Dr. Barnett E. Winters, New Straitsville, were burned, September 27, with a loss of $2,500.——Dr. Henry H. Bowman, Canton, was seriously injured by the discharge of a gun in the hands of a companion, while hunting near Harlem Springs, September 16.——Dr. James A. Hubbell, Quincy, was seriously injured in a runaway accident, September 11.——Dr. Albert F. Spurney, Cleveland, has sailed for Europe.——Dr. John P. DeWitt, Canton, has returned from abroad.

Cincinnati

Hospital Ready.—The new Cincinnati Hospital will be ready for public inspection, October 19 and 26.

Personal.—Dr. Christian B. Holmes has been appointed dean of the medical department of the University of Cincinnati, succeeding Dr. Paul G. Woolley.——Dr. Theodore Wenning has returned after service in a Servian military hospital during the Balkan war.

PENNSYLVANIA

Medical Scholarship for Women Students.—A congress of women's clubs of Western Pennsylvania has pledged itself to place a scholarship, valued at $12,000, in the medical school of the University of Pittsburgh, for the benefit of women students. In furtherance of this plan a banquet was given at the Fort Pittsburgh Hotel, Pittsburgh, October 11, at which Dr. William M. Polk, president of the New York Academy of Medicine, Dr. Evangeline W. Young, founder of the School of Eugenics, Boston, and others, spoke.

Personal.—Dr. Samuel G. Dixon, state commissioner of health, was operated on for abdominal abscess in the University Hospital, Philadelphia, October 3, and is reported to be making satisfactory progress toward recovery.——Dr. Cyrus B. King, Pittsburgh, fell on the floor of a bank in Pittsburgh, October 4, fracturing his femur.——Dr. Edward B. Shellenberger, Warren, has been appointed assistant medical inspector of dispensaries by the state commissioner of health.——Dr. George R. S. Corson, Pottsville, has been elected secretary of the Schuylkill County Antituberculosis Society.

Philadelphia

Typhoid Still Prevalent.—Typhoid fever is still prevalent in the city, despite the efforts of the health authorities to stamp it out. The number of new cases of the disease reported during the past week aggregated sixty-five. This is an increase of eleven over the number reported in the preceding week.

Personal.—Dr. Charles A. O'Reilly has returned from abroad.——Dr. W. T. Robinson, while leaving church, October 2, was stricken with cerebral hemorrhage and is reported to be in a serious condition in the University Hospital.——Dr. Edward B. Hodge was seriously injured, October 3, in a collision between his motor-car and a street-car on the Chestnut Street bridge, and is under treatment in the Presbyterian Hospital.

Foreign Visitors.—Dr. Roger Croissant, Paris, visited Philadelphia October 6, to study the system of training nurses with a view of organizing similar work in France.——Dr. Giuseppe Bastianelli, Rome, is spending several days in this city visiting the medical institutions.——Dr. Adolf Engler, professor of botany in the University of Berlin, and Dr. Karl Freiherr von Tubeuf, professor of botany in the University of Munich, are the guests of Professor Harshberger, of the University of Pennsylvania.

For Healthier Babies.—A baby improvement contest, for the purpose of arousing mothers in congested sections of the city to strive for better hygienic environment for their children, will be inaugurated November 15 by the newly formed Child Federation. A resolution authorizing this step was adopted at a meeting of the federation October 8. The contest will be carried on in certain districts of the city and each will cover a period of eight weeks. A prize in the form of cash or a medal will be offered to the mothers whose babies show the greatest improvement eight weeks after entering the contest. The work of the mothers will be outlined and directed by the members of the federation. The resolution was proposed by Dr. Samuel McClintock Hammill.

Demands Sanitary Barber Shops.—The director of public health, Dr. Joseph S. Neff, has issued a warning against barber shops which persist in practicing insanitary methods. Efforts are to be made to compel institutions of this character to instal modern sanitary apparatus for the proper sterilization of materials used in the work. Dr. Neff is preparing a law for the licensing of barbers and the following are some of its provisions: The registration of all barber shops. The prohibition of the use of any article which is not sterilized by a recognized process after each use. The refusing of barbers' licenses to persons suffering from skin or other communicable diseases. No powder puff, sponge or finger bowl must be used for a customer. Customers suffering from skin or other communicable diseases must not be waited on unless the instruments used belong to the individual in question.

UTAH

New Officers.—Fifth District Medical Society at Ogden: president, Dr. Herbert A. Adamson, Richmond; secretary-treasurer, Dr. Carlyle K. MacCurdy, Ogden.

Personal.—Dr. George H. Christy, Vernal, was operated on at the Latter Day Saints' Hospital, Salt Lake City, for appendicitis, September 18.——Dr. Harry B. Forbes, Ogden, has returned after a trip around the world.

New Officers of State Association.—The nineteenth annual meeting of the Utah State Medical Association was held in Salt Lake City, September 23 and 24, and the following officers were elected: president, Dr. John F. Critchlow, Salt Lake City; vice-presidents, Drs. Joseph R. Morrell, Ogden; Heber E. Robinson, American Fork, and Margaret A. Freece, Salina; secretary, Dr. W. Brown Ewing, Salt Lake City (reelected); treasurer, Dr. Howard P. Kirtley, Salt Lake City (reelected); councilor for the third district, Dr. Horace G. Merrill, Provo; delegate to the American Medical Association, Dr. Sol G. Kahn, Salt Lake City; and alternates, Drs. William R. Tyndale, Salt Lake City, and Robert S. Joyce, Ogden. It was decided to hold the 1914 meeting in Salt Lake City.

VIRGINIA

Antitoxin May Be Secured at Any Time.—The State Board of Health has arranged for the all-night attendance of at least one employee at office in Richmond to insure the prompt shipment of diphtheria antitoxin.

New Society Organized.—Pursuant to a request from Dr. Southgate Leigh, president of the Medical Society of Virginia, a meeting of physicians of Lunenburg County was held in Victoria, September 16, and the Lunenburg County Medical Society was organized, with the following officers: president, Dr. Thomas C. Harris, Kenbridge; vice-president, Dr. Walter E. Vest, Meherrin, and secretary, Dr. Edward P. Oden'hal, Victoria.

Personal.—Dr. and Mrs. Charles R. Grandy, Norfolk; Dr. and Mrs. Edward H. Miller, Jr., Danville; Dr. Stuart McGuire, Richmond, and Dr. Leigh Buckner, Roanoke, have returned from Europe.——Dr. and Mrs. Charles W. P. Brock, Richmond, celebrated their golden wedding anniversary, October 1.——Dr. Samuel S. Snarr, Wheatfield, was seriously burned in a gasoline explosion, recently, and is under treatment in Memorial Hospital, Winchester.——Dr. W. B. Dodge, Stuarts Draft, was thrown from his automobile recently, dislocating his right shoulder.

New Officers.—Sussex County Medical Society, at Petersburg: president, Dr. Lee O. Vaughan, Waverly; vice-president, Dr. Joseph F. Slade, Sussex; secretary, Dr. Clarence P. Neblett, Burts.——Accomac Medical Association at Olney, September 28: president, Dr. Fletcher Drummond Parksley; secretary, Dr. John W. Robertson, Onancock.——Old Dominion Medical and Surgical Society—fourth annual session at Petersburg: president, Dr. Thomas J. Fawcett, Lynchburg; secretary, Dr. W. Alexander Crowder, Petersburg; coresponding secretary, Dr. Harrison L. Harris, Richmond. Lynchburg was selected as the next place of meeting.——Shenandoah Valley Medical Association at Woodstock: president, Dr. William P. McGuire (reelected); secretary, Dr. J. M. Allen, both of Winchester.

WISCONSIN

Health District Heads.—The governor has appointed the following district health officers under the law passed by the last legislature: Drs. Guy W. Henika, Beaver Dam; W. C. Bennett, Oregon; J. M. Furstman, LaCrosse, and L. E. Spencer, Wausau.

New Officers.—Wisconsin State Medical Society, First District Branch, at Oconomowoc, September 12: president, Dr. Henry G. B. Nixon, Hartland; secretary-treasurer, Dr. S. Breck Ackley, Waukesha.——Wisconsin State Medical Society, Second District Branch, tenth annual meeting at Racine: president, Dr. George H. Young, Elkhorn; secretary-treasurer, Dr. Milton V. DeWire, Sharon.

To and From Europe.—Dr. Charles W. Giesen, Superior, and family, left for Europe, October 4. At a farewell banquet, Dr. Giesen was presented with a gold watch by members of the profession of Superior and other friends.——Dr. Luther A. Potter, Superior, has returned from Europe.——Dr. John W. Lee, Superior, sailed for Europe, September 23.——Drs. Soren Sorenson and J. Sotheran Keech, Racine, have returned from Europe.——Dr. Maurice L. Henderson and Dr. and Mrs. James H. Hackett have returned from Europe.

Medical Women Meet.—The Wisconsin Medical Women's Society held its fourth annual meeting at Milwaukee, September 30 and October 1, and elected the following officers: president, Dr. Julia Riddle, Oshkosh; vice-president, Dr. Carrie A. Frost, Chippewa Falls; secretary, Dr. Irene G. Tomkiewicz, Milwaukee, and treasurer, Dr. Helen Binnie, Poynette. The society adopted a resolution petitioning the legislature to pass an amendment requiring a certificate of health from men as well as from women before the issuance of marriage licenses.

State Secretaries Meet.—At the annual meeting of the State Association of County Secretaries, October 1, the following officers were elected: president, Dr. Joseph F. Smith, Wausau; vice-president, Dr. Daniel Hopkinson, Milwaukee, and secretary, Dr. L. Rock Sleyster, Waupun. A committee consisting of Dr. William Zierath, Sheboygan, Joseph P. McMahon, Milwaukee; Theodore J. Redlings, Marinette; Charles S. Sheldon, Madison, and George E. Hoyt, Menomenee Falls, was appointed to confer with the legislative committee of the State Medical Society in regard to medical legislation in Wisconsin.

Personal.—Dr. George E. Hoyt, Menomenee Falls, recently appointed district health officer, has been declared ineligible, as he already is a member of the state senate.——Dr. John N. Rock, Milwaukee, sustained a compound fracture of the right arm while cranking his automobile about two weeks ago. He is now improving after a tedious illness due to infection of the wound.——Dr. Gilbert E. Seaman, Milwaukee, has been appointed surgeon general of the state, vice Dr. Edward H. Grannis, Menominee, resigned.——Dr. Ulysses G. Darling, Lake Geneva, has been appointed assistant professor of mental diseases and clinical neurology in the medical department of the University of Illinois.

State Society Election.—The Wisconsin State Medical Society held its sixty-seventh annual convention in Milwaukee, October 1 to 3. The following officers were elected: president, Dr. Charles S. Sheldon, Madison; vice-presidents, Drs. Curtis A. Evans, Milwaukee; Clarendon J. Combs, Oshkosh, and Edward Kinne, Elkhorn; councilors, Drs. William F. Zierath, Sheboygan, fifth district; Henry W. Abraham, Appleton, sixth district, and Thomas H. Hay, Stevens Point, ninth district; delegate to the National Legislative Council of the American Medical Association, Dr. Arthur J. Patek, Milwaukee; delegate to the Council of Medical Education of the American Medical Association, Dr. Henry B. Hitz, Milwaukee; delegate to the American Medical Association, Dr. John M. Dodd, Ashland, and alternate, Dr. John F. Pember, Janesville. Oshkosh was selected as the place of meeting for 1914.

GENERAL

Southern Physicians to Meet.—The annual meeting of the Southern Medical Association will be held in Lexington, Ky., November 18-20, under the presidency of Dr. F. A. Jones, Memphis.

Railway Surgeons to Meet.—The New York and New England Association of Railway Surgeons will hold its twenty-third annual session at the Hotel Astor, New York, October 22, under the presidency of Dr. J. W. Le Seur, Batavia, N. Y.

Corrected List of Traveling Society Officers.—The following is a corrected list of the officers of the American Society for Physicians' Study Travels: presidents, Drs. James M. Anders, Philadelphia, William J. Mayo, Rochester, Minn., Lewellys F. Barker, Baltimore, and Rudolph Matas, New Orleans; secretary-general, Dr. Albert Bernheim, Philadelphia.

Railway Surgeons' Convention.—The sixth annual meeting of the Association of Surgeons of the Norfolk and Western Railway was held October 2 and 3 and the following officers were elected: president, Sparrell S. Gale, Roanoke, Va.; vice-presidents, Drs. William B. Morrison, Hagerstown, Md., Philip H. Kelley, Vivian, W. Va., George M. Marshall, Portsmouth, Ohio, Richard E. Venning, Charlestown, W. Va.; secretary-treasurer, Dr. Thomas D. Armistead, Roanoke, Va.

Southwestern Physicians Hold Meeting.—The annual meeting of the Medical Association of the Southwest was held in Kansas City, Mo., October 6-8, and the following officers were elected: president, Dr. S. S. Glasscock, Kansas City, Kan.; vice-presidents, Drs. Jefferson D. Griffith, Kansas City, Mo., James E. Dodson, Vernon, for Texas; David A. Myers, Lawton, for Oklahoma, and Leonard R. Ellis, Hot Springs, for Arkansas; and secretary-treasurer, Dr. F. H. Clark, El Reno, Okla. (reelected). The next meeting will be held in Galveston, Tex.

Death of Professor Kutner.—The cable announces the death of Prof. Robert Kutner of the University of Berlin, aged 46. He has been in charge of the Empress Frederick House for Medical Study, the central headquarters for official postgraduate instruction in Germany, ever since its foundation in 1906. He has also been the editor of the official organ of the "Aerztliche Fortbildungswesen," as the entire postgraduate movement is called. Kutner has published several works on urologic subjects, and was the first who succeeded in photographing the interior of the bladder. A description of the Empress Frederick House was published in The Journal, March 24, 1906, page 894. The information bureau conducted there has been of great use to students of the medical sciences.

Mississippi Valley Association Meeting.—Mississippi Valley Medical Association will meet in New Orleans, October 23-25. At the close of the meeting arrangements have been made for a special trip to the Panama Canal Zone. The steamer *Turrialba* has been chartered, and will sail from New Orleans, October 25. The boat is scheduled to arrive in Colon, October 30, remaining until the evening of November 3; arriving at Bocas del Toro the next morning and remaining there twenty-six hours. On the return trip she will arrive in Colon on the morning of November 6, and will arrive in New Orleans on November 11. On the first day there will be symposiums on "Social Hygiene" and "The Kidney." In the evening the address by the president on "The Civic Importance of Some Phases of the Neuroses, with Suggestions as to Their Control"; the address in surgery, by Dr. William L. Rodman of Philadelphia, on "Carcinoma, Especially the Precancerous Stage"; the address in medicine, by Dr. Henry B. Favill, Chicago, on the "Child Culture, the Prime Function of Organized Medicine"; and the memorial address by Dr. John A. Witherspoon of Nashville, Tenn., will be delivered. On the second day there will be a symposium on "The Circulation and Blood-Pressure"; and the third day symposiums on "Pediatrics" and "Anaphylaxis."

The Modern Hospital: A New Journal.—"An agent for the collection and dissemination of experience and knowledge concerning their (hospital workers') common service to humanity." As such this new entrant on the field of medical journalism is announced. Needless to say, there is need for a journal devoted to the business as well as the professional side of the present-day hospital. There are at present 6,665 hospitals in the United States, with a capacity of more than 600,000 beds, representing an investment in lands, buildings and equipment of at least $1,500,000,000, and an annual maintenance outlay of $250,000,000. It is these interests that this journal is intended to serve. The general appearance of the journal is pleasing; the advertisements are in no way objectionable; the reading matter is of the highest type, consisting of articles from such men as A. J. Ochsner, A. W. Dunbar, J. G. Mumford, H. B. Howard and others—a total of sixty-eight pages of reading matter of varied interest to those interested in the hospital problem. The editorial staff should be commended for the plan and arrangement of the journal. It should meet with a favorable reception.

Bequests and Donations.—The following bequests and donations have recently been announced:

The New York Hospital for Scarlet Fever and Diphtheria Patients, $15,000 by the will of Mrs. Louisa Mintern.

Presbyterian Hospital, New York City, $12,500 by the will of Otis K. Dimock.

Beth Israel Hospital, New York City, $5,000; Mount Sinai Hospital, $3,000; United Hebrew Charities, $2,500; Lebanon Hospital and Montefiore, each $1,500; the Hospital for Deformities and Joint Diseases and Har Monah Hospital, each $1,000 by the will of Samuel J. Silverman.

Mount Sinai Hospital, New York City, Montefiore Home, and German Hospital, each $2,500 by the will of Max E. Bernheimer.

Royal Victoria Hospital, Montreal; Montreal General Hospital, and Montreal Maternity Hospital, each $50,000, and Royal Alexandra Hospital for Infectious Diseases, Montreal, and Ross Memorial Hospital, Lindsey, Ont., each $25,000 by the will of Mr. James Ross of Montreal.

The Hospital of the Protestant Episcopal Church, Philadelphia, $10,000, and the trustees of the University of Pennsylvania $50,000 by the will of Anna Blanchard.

Galesburg (Ill.) Cottage Hospital, $15,000 by the will of Mary Davis McKnight.

Methodist Hospital, Indianapolis, a donation of $1,500 by Thomas B. Rooker of Mooresville, Ind.

College of Physicians and Surgeons, New York City, a gift of $2,500 from Clarence K. Mackay for surgical research.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Oct. 4, 1913.

The Radium Institute: Important Discoveries

From the Radium Institute some important discoveries in radium therapy are announced. The quantity of radium in the institute is, at the present price of the value of $400,000, and amounts to 4 gm. At the institute it has been demonstrated that the radium emanation has exactly the same properties as pure radium and is as efficient for curative purposes. This is a discovery of the highest practical importance, for previously radium treatment could be given only at the institute, as it was not practicable to lend this extremely valuable and limited substance. Now the emanation fixed in a hollow plate or tube is sent out to physicians for use on patients. Thus if a physician wants 200 mg. of radium for use on a patient its cost, $20,000, would be prohibitive. But for a comparatively trifling sum the institute can supply a plate containing radium emanation which will have the same effect. There is this difference, however, the activity of the emanation decreases, falling to one-half strength in three and one-half days. At present, 1 gm. of radium is devoted wholly to producing emanation for distribution, and as the demand is so great 1.5 gm. is about to be used. Another branch of the activity of the institute is the supply of water impregnated with radium emanation for consumption in certain affections. The institute is supplying radium emanation solution of a strength of from 1 to 2 millicuries per liter. The Radium Institute was opened in August, 1911, and since that time the work has steadily increased. At first it was open from 8 a. m. to 6 p. m. for the purpose of treating patients. So numerous were the poor patients that a night clinic had to be added sixteen months ago. It is open until 11:30 p. m., and sometimes until midnight. The building contains duplicate sets of apartments — one for the accommodation of paying patients and the other for the poor. No patient is seen except on the introduction of a physician. Most of the poor patients are sent from the hospitals. During the past eleven months about 800 patients had been treated and over 7,000 treatments have been administered. During the month of August the institution was closed in order that members of the staff, who were working at high pressure and all of whom have radium burns on their hands, might have a holiday and rest, which is the only known cure for these burns. There are in the institute forty-two pieces of radium apparatus, adapted for application to various parts of the body. Radium has been mounted on apparatus for several hospitals and institutes in the United States, Germany and Denmark. The reason why the applications have been made for apparatus from abroad is that by experiments extending over several months the staff has succeeded in producing a varnish which will withstand the action of heat, antiseptics, alcohol and other influences.

The British Medical Association and the Insurance Act; Threatened Fission

Though the insurance act is working fairly smoothly all over the country and friction is not more than is to be expected under a new scheme of such magnitude as to provide for medical attendance on the whole working-class population of the country, it appears to be exerting a profound disruptive effect on the British Medical Association. It may be remembered that just before the act came into operation, at the beginning of the year, the British Medical Association attempted to prevent the working of medical benefit by ordering those who had signed "the pledge" not to undertake service under the act. This order was disobeyed by the greater part of the physicians involved. Subsequently the association released the remainder from the pledge. Thus there are in the association several bodies who may be described as "first panel men," "second panel men" and "antipanel men" (those who still will have nothing to do with the act). As might be expected, the action of the first panel men has aroused considerable resentment among the others. The question whether or not they were justified in their action was discussed in THE JOURNAL at the time. Not only is there the ill feeling between those who are working the act and those who will not, but also there is a clash of interests. The non-panel men have lost some of their patients, as insurance is compulsory and free attendance is provided. They continue to demand that the insured should be given the power of contracting out of the act, and the money provided for medical benefit allotted to them. Some of them have gone so far as to ask that the old control by friendly societies of medical benefit be restored so that they might be enabled to perform the work outside the act; yet the abolition of this control was one of the association's points. This would obviously not be to the advantage of the panel physicians, who would lose patients. A non-panel medical league has been formed to federate various non-panel associations which have come into existence all over the country. The number of non-panel physicians is estimated at from 6,000 to 10,000, but a good many of these do not practice in the industrial classes, and therefore are not parties in the struggle. The non-panel men maintain that they uphold the original claims of the British Medical Association, and that the association pronouncement that the act is "derogatory to the profession" has never been rescinded. Dissatisfaction has arisen because the British Medical Association, being in the unfortunate position of having to consider the interests of all its members, cannot satisfy both parties. The non-panel men now complain that it has not found the time or the energy to develop strong action on their behalf. This dissatisfaction has reached such a pitch that one of the metropolitan divisions, the Wandsworth, has by a majority resolved that "the present propanel attitude of the association is reacting detrimentally to the interests of members of the profession in general and in particular to the interests of non-panel practitioners, and approves the action of all such members resigning from the association." It is stated that resignations are being received from all over the country; but whether the number will be serious or not remains to be seen. The position which has arisen is somewhat curious, because when the act came into force the trouble of the association was of an exactly opposite kind. As pointed out in THE JOURNAL at the time, the machine was captured by the extreme opponents of the insurance act, and some of the most important and active members of the association, Sir Victor Horsley, Dr. McLean (chairman of the representative body), Dr. Lauriston Shaw (chairman of the ethical committee), and others who believed the extreme policy to be disastrous, resigned from the association. At the same time a new organization of physicians, opposed to the policy of the association and entirely in favor of working the act (the State Service Medical Association), was formed. Thus the association has lost supporters, first because its opposition to the act was so extreme, and now because it is not sufficiently extreme. It has to support those who are working the act and form the greater part of its members. The extremists are certainly doing no good for themselves and only harm to the association. It is their policy which was responsible for the humiliating defeat of the association by the government. The association had obtained by its efforts greatly improved terms and would have done much better to rest on its laurels, consent to work the act and then direct its attention to improving its defects which the operation of the act would disclose. They would not have lost the ear of the government and would have avoided defeat and these dissensions. The extreme party is showing itself more stupid than ever, for their policy has become still more hopeless. They represent only a minority of the profession, and although they receive some encouragement from the conservative press, anxious to embarrass the government in every possible way, they have no political support which could be of any service. If the conservative party, in which alone they can have hope, came into power, it would have to consider the votes of the millions who form the friendly societies much more than the few thousand discontented doctors.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Oct. 2, 1913.

Death of the Chemist, Jules Ogier

The eminent chemist, Jules Ogier, doctor in physical sciences, formerly president of the Société de chimie and a member of the Comité consultatif d'hygiène publique de France, is dead at the age of 60 from an affection of the heart. By his death chemistry has lost one of its most celebrated representatives who ought even to be considered, from one point of view, a creator of the science. After being assistant in chemistry at the Ecole supérieure de pharmacie de Paris, Ogier became assistant to the great chemist Berthelot at the Collège de France. From this time Ogier published remarkable works. In 1883 Brouardel appointed him director of the toxicologic laboratory in the medicolegal service of the Paris prefecture of police, and for the next thirty years his findings were of the utmost importance. His work in public hygiene included the study of *introducing water into* most of the large cities of France; the processes of the purification of drinking-water; the substitution of zinc white for white lead, the distribution of the sewage of Paris, etc. He had numerous pupils and wrote thirty volumes of judicial reports and many works of great value, including his Traité de chimie toxicologique, which appeared in 1899 and is universally recognized.

Similar Susceptibility of Both Strong and Weak to Virulent Microbes

September 22, at the Académie des sciences, A. Chauveau reported the experiments which have convinced him that the strong are as apt as the weak to contract virulent diseases, those of short duration like sheep-pox, as well as those which develop very *slowly, like tuberculosis. Chauveau believes that* it would be chimerical to attempt to destroy the plague of tuberculosis by trying to render the organism immune by suppressing all the causes of physical pain. Direct action against the tuberculous agent and the protection of healthy persons from those who harbor the bacillus are the only means which can be used against the ravages of the disease. These *logical measures applied against the propagation of* virulent *maladies of man and the lower animals constitute,* besides, the basis of general rules of hygiene both public and private. According to Chauveau, an exception in the case of tuberculosis would be scientific nonsense.

Beginnings of the Pasteur Treatment of Rabies

I *have already spoken of the celebration of the twenty-fifth* anniversary of the founding of the Institut Pasteur (The Journal, Oct. 4, 1913, p. 1307). Dr. A. Loir, a nephew of Pasteur and director of the Bureau d'hygiène du Havre, has published in the *Bulletin médical* interesting memories of certain episodes connected with the discovery of the Pasteur treatment that are known to few, if any.

Pasteur had proved *that animals could be immunized* against rabies *even if bitten. At this time, July, 1885, an* Alsacian child, young Meister, who had been severely bitten by a mad dog, came to his laboratory. Pasteur consulted Vulpian and Grancher, and they believed that the child was practically certain to die, and that the treatment which had been a success with animals ought to be tried. Grancher made the inoculations *through eighteen days, and during this* time Pasteur lived in constant anguish. On all sides he was being criticized, in some instances violently, for his method. This hurt him, but he was confident and he went ahead. Six months afterward, the shepherd Jupile came to the laboratory, bitten in the hand by a rabid dog. To-day Jupile is concierge at the Institut Pasteur.

Dr. Loir relates that *several weeks after the arrival of the* shepherd, Grancher was wounded in handling the virus and decided on immediate inoculation. Deeply moved, Pasteur gave his assent, but insisted on being inoculated too, since he did not wish Grancher to run the risk alone, the success of the treatment not yet having been established. Grancher flatly refused, and Pasteur was much annoyed by his refusal.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Sept. 26, 1913.

Personal

Professor Löhlein of Leipsic has been appointed prosector at the municipal hospital and director of the bacteriologic examination office in Charlottenburg.

Potassium Cyanid in Hotels

Lately potassium cyanid has been used for cleaning silverware in hotels. The public-health authorities (Wissenschaftliche Deputation für das Medizinalwesen) have protested against this use of potassium cyanid and *other substances* which may develop hydrocyanic acid *on mixing* with acids. On the basis of this report an ordinance has been passed prohibiting the use of potassium cyanid and similar compounds for the cleansing of metal dishes and tableware in hotels, restaurants, sanatoriums, etc. The use of this poison violates the provisions of the police ordinance dated February 22, 1906, regulating the traffic in poisons.

Municipal Purchase of Mesothorium

The great rush for the purchase of mesothorium and radium by municipalities, already noted, has been suddenly checked by the city of Munich. The city government of that city has refused *for the present* to carry out the resolution to buy $50,000 (200,000 marks) worth of this costly material. It is believed that there are positive evidences that the factories engaged in producing mesothorium are raising the price unduly. For this reason, more exact information is to be obtained by the municipal authorities before the purchase of *the* preparation is consummated in Munich and other cities.

German Congress on Welfare Work for Infants

At the congress held in Breslau in the middle of September the important questions of the declining birth-rate and of infant hygiene held the first place for discussion. The leading address was by an authority on economics, Professor Julius Wolf of Breslau, who showed that since the seventies the birth-rate *in Germany* has steadily declined. The number of births was at first restricted only among *the upper classes, but* this phenomenon has steadily spread to other strata of society, and at present even the working people make restriction of births the law of marriage. A lessening of the number of children at the present time presents many economic advantages *for the household and for the* personality of the wife. Unfavorable pecuniary conditions accentuate the *tendency to* restrict the number of births, and a favorable turn of affairs following later scarcely lessens this tendency. However, this is true only for the cities. In the rural districts another law holds. There children are regarded as assets, at any rate *during periods when there is a dearth of farm-hands.* Families with many children should be given advantages in wages and in taxes, and care should be taken that the children who are already born are kept alive by the measures of infant and child hygiene, and finally, the hindrances should be removed which at the present time induce parents to limit their offspring. There is no need to fear depreciation in the quality of the offspring *if the decline of the birth-rate is checked.*

The second speaker was Professor Langstein, director of the Kaiserin Augusta-Viktoria House at Berlin, who discussed the problem from the standpoint of the physician. The view that the reduction in births is occasioned by racial degeneration, venereal diseases, or alcoholism, is not sustained by reliable evidence. The reduction in births is essentially to be attributed to *voluntary limitation of the number of children.* The *opposition* to this decline in the birth-rate must therefore be based on this fact, and it will be effectual as a rule only through economic measures. For the present, the essential efforts in the depopulation question must be along the lines of combating infant mortality. It is evident that the higher mortality of children in families with many children is not an inherent necessity, and the success of infant welfare work has been demonstrated in figures again and again. However, statistical investigation in various circles of society shows that a greater danger seems to threaten the child in a family with a higher birth-rate. Thorough statistical investiga*tion and care*ful analysis by physicians studying infant hygiene of the fate of children *from* families with many children furnish the answer that only in the rarest cases the death of the child is dependent on the number of children in the family, and that the mortality depends far more on the kind of care and nourishment which they receive than on the number *of children.* Investigation has shown *that in a number* of families in which all the children were breast-fed for at least thirty weeks, there was scarcely any difference in the *infant* mortality between families with a smaller and those with a greater number of children. This fact, that breast-*feeding* is able to maintain even a large number of *children* healthy and vigorous, places before us *the task of* using all the means *afforded by infant welfare* work to induce mothers to return to the natural mode of nutrition. The experience of physicians shows also the evils of the one- and two-child systems. *To be an* only child, of itself, almost always means *disease.* Race degeneration must occur in a class of the population in which the two-child system prevails. On the other hand, it is indicated by statistics that a favorable position is held by the third-born *child.* The selective influence of infant mortality, in the sense of Darwin, has been disproved. The view that in *countries* with a higher infant mortality the fitness for military service is better, and tuberculosis less frequent, is denied. Thanks to the advance of pediatrics, we are not so helpless in reference to the feeble physical constitution of children as previously. By individualizing diet and care we can develop *capable* individuals out of constitutionally inferior infants.

Deaths

Reginald Heber Fitz, M.D., died of ulcer of the stomach, September 30. With the death of Dr. Fitz there passed away a great physician and teacher who made contributions to medical literature that always will be a source of credit to American medicine.

Born at Chelsea, Mass., in 1842, Dr. Fitz graduated from Harvard in 1864 and took up the study of medicine under the direction of Jeffries Wyman, eminent physician and anatomist, at the same time taking the lectures at the Harvard Medical School, from which he received his medical degree in 1868. In the meantime he served as house officer in the Boston City Hospital. Immediately after graduation from the medical school he went to Europe and there he worked with Oppolzer and Skoda in Vienna, Virchow in Berlin, Cornil in Paris, and Murcheson in London, returning to Boston in 1870. At this time he published in Virchow's *Archiv* an article on bronchiectasis. He became microscopist to the Massachusetts General Hospital and instructor in pathological anatomy in the Harvard Medical School, and shortly afterward assistant professor of pathology, achieving almost at once a name as a thorough, skilful and reliable pathologist. At about this time the system of instruction in Harvard Medical School was rearranged into graded courses and Dr. Fitz as secretary of the faculty exercised much influence on medical education. In 1878 he was made professor of pathological anatomy and his pupils love to tell of his clear-cut, concise, and effective way of teaching. In 1887 he was appointed visiting physician to the Massachusetts General Hospital and in 1892 professor of medicine in the Harvard Medical School, retiring in 1908. The long apprenticeship that he served in pathological anatomy in preparation for his clinical work is especially noteworthy. In 1886 he published* the article that will carry his name farthest, because thereby he finally established the importance of perforation of the appendix. This article is a medical classic. Two or three of his conclusions may be repeated:

Reginald Heber Fitz, 1842-1913

"The vital importance of the early recognition of perforating appendicitis is unmistakable.

"The diagnosis in most cases is comparatively easy.

"Its eventual treatment by laparotomy is generally indispensable."

Another classical article is the one entitled "Acute Pancreatitis," in which he established the occurrence and symptoms of acute inflammatory processes in the pancreas. His contributions to medical literature were not numerous, the number of titles being about thirty-eight. On his sixty-fifth birthday his former pupils at the hospital and his assistants issued a volume in his honor entitled "Medical Papers Dedicated to Reginald Heber Fitz." He received numerous other medical honors. In the "Medical Papers" A. K. Stone writes as follows:

"The work that Dr. Fitz has done during the active period of life has been largely critical and judicial, though always with a constructive tendency. He has formed his opinions for himself, and then bravely stood by them, even at times when they were in opposition to those of a majority of his friends. . . . His general position has been that of a conservative and critical counselor rather than a radical leader. His industrious habits or work have been individualistic on the whole. He has studied the work of others, rearranged their ideas or presented them in a new and true light to the world, but has not sought to be the leader of a group of students searching for new facts. Yet his personal industrious application of study has been a source of inspiration to those who have had the good fortune to be his students and associates."

Harry Boyle Runnals, M.D. M.R.C.S., England, 1897; formerly of Skagway, Alaska; from 1888 to 1892 surgeon in the U. S. Indian Service for the district from Tillamook to Vancouver Island; chief surgeon for the Northwest Mounted Police, and chief surgeon for the White Pass and Yukon Railroad; later a practitioner in Puyallup, Wash.; died at the home of his son in Melmont, Wash., September 10, from cerebral embolism, aged 59.

Bennett Wood Green, M.D. University of Virginia, Richmond, 1855; assistant surgeon U. S. Navy. until the outbreak of the Civil War, when he resigned to become a surgeon in the Confederate Navy; and afterward for several years a practitioner of Cordoba, Argentine Republic; later a resident of Charlottesville, Va.; died in the University Hospital, Baltimore, August 3, from heart disease.

Daniel Crosby Greene (license, years of practice, Massachusetts); a missionary of the American Board Commissioners for Foreign Missions in Japan since 1869, and on whom the Order of the Rising Sun, third class, was bestowed by the Emperor of Japan in June last; a veteran of the Civil War; twice president of the Asiatic Society, Japan; died in Tokio, September 15, aged 70.

Orren Burnham Sanders, M.D. Boston University School of Medicine, 1879; of Boston; a Fellow of the American Medical Association; for many years a member of the faculty of his alma mater; who was thrown from his car in a collision with another motor-car in Quincy, Mass., September 22; died from his injuries in the Quincy City Hospital, September 25, aged 57.

Hiram S. Plummer, M.D. College of Medicine and Surgery, Cincinnati, 1860; Illinois Army Board, 1862; assistant surgeon of the 110th Illinois Infantry, U. S. V., and later surgeon of the 152d Illinois Infantry, U. S. V., during the Civil War; since that time a practitioner in Mount Vernon, Ill., and once mayor of that city; died at his home, August 28, aged 82.

William Eberle Shaw, M.D. Medical College of Ohio, Cincinnati, 1873; a Fellow of the American Medical Association; for thirty years a practitioner of *Cincinnati*, and a member of the staff of Christ Hospital; was killed accidentally at his ranch in Santa Rosa, Cal., September 5, by a fall from a tree.

Edwin Candee Baldwin, M.D. Bellevue Hospital Medical College, 1896; a Fellow of the American Medical Association; for thirteen years chief bacteriologist for the Port of New York, and pathologist to St. Vincent's Hospital; died at his home in Rosebank, Borough of Richmond, October 3, aged 48.

Morgan T. Micou, M.D. Tulane University, New Orleans, 1902; of Clifton Forge, Va., and later of Charlottesville, Va.; died at his home, September 4, from diabetes, aged 33.

---

* Am. Jour. Med. Sc., 1886, xcii, 321.

Fred Eugene Parker, M.D. Dartmouth Medical School, Hanover, N. H., 1899; for eight years physical instructor of Brown's University, Providence, R. I., and director of the gymnasium; later a practitioner of Hoxsie, R. I.; died recently at his home in Victoria, B. C., from septicemia, aged 44.

Hugh Matthewson Patton, M.D. McGill University, Montreal, Que., 1890; New York Homeopathic Medical College, New York City, 1891; a justice of the peace of Montreal and one of the founders of the Homeopathic Hospital; died at Little Metis, Que., September 5, aged 47.

Paul George McConnell, M.D. Western Pennsylvania Medical College, Pittsburgh, 1899; formerly a member of the American Medical Association; a member of the Medical Society of the State of Pennsylvania; died at his home in Beaver, about September 17, aged 39.

Rufus Raymond Raessler, M.D. Jefferson Medical College, 1894; local surgeon at Anthon, Iowa, for the Illinois Central Railroad; for twenty years a practitioner of that town; died in a hospital in Sioux City, Iowa, September 7, from nephritis, aged 43.

John Turner Cushing, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1864; a surgeon of volunteers during the Civil War, and later for several terms, mayor of Huron, Ohio; died at his home in Turner, Me., September 17, aged 82.

Charles Elwyn Fogg, M.D. Rush Medical College, 1879; a fellow of the American Medical Association; died at his home in McConnell, Ill., September 18, from the effects of morphin self-administered, it is believed with suicidal intent, aged 60.

Albert T. Brundage, M.D. Castleton (Vt.) Medical College, 1840; a member of the Medical Society of the State of Pennsylvania; for nearly fifty years a practitioner of Susquehanna County, died at his home in Harford, September 14, aged 93.

Herman F. Schenck, M.D. Medical College of Evansville, Ind.. 1882; a veteran of the Civil War; died at his home near Oakland City, Ind., September 12, from injuries received four weeks before in a runaway accident, aged 66.

Lorin Hall, M.D. Bellevue Hospital Medical College, 1880; formerly a member of the faculty of the University of Michigan, and for ten years a practitioner of Chicago; died at his home in Wilmette, Ill., October 9, aged 59.

John M. Smith, M.D. Medical College of the State of South Carolina, Charleston, 1868; a Confederate veteran; a leading citizen of Williston, S. C.; died at the home of his daughter, September 11, from heart disease, aged 68.

Weston Theodore Plumb, M.D. Rush Medical College, 1874; for twenty years a practitioner of Van Cleve, Iowa, and later of Tama, Iowa; died at his home in South Toledo, Iowa, September 8, from heart disease, aged 65.

Domenico Nicola Golini, M.D. University of Naples, Italy, 1900; a prominent member of the Italian colony of Providence, R. I.; died at his old home in Capriata, Volturno, Italy, September 14, from pneumonia, aged 40.

William Henry Kirk Davis, M.D. New York University, New York City, 1887; a Fellow of the American Medical Association; died suddenly from nephritis in his office at East Orange, N. J., September 24, aged 50.

Alfred H. Lee, M.D. University of Pennsylvania, Philadelphia, 1865; of Easton, Pa.; surgeon of volunteers during the Civil War; died in the Easton Hospital, August 25, after a surgical operation, age 73.

William Rex Paterson, M.D. Buffalo (N. Y.) Medical College, 1901; for three months after graduation in government service in Cuba; died in his home at Lloydell, Pa., September 6, from nephritis, aged 39.

William A. Bradford, M.D. University of Louisville, Ky., 1882; a member of the State Medical Association of Texas; died at his home in Birthright, August 2, from carcinoma of the stomach, aged 61.

Lester R. Riggs, M.D. Eclectic Medical Institute, Cincinnati, 1901; formerly an attorney of Salt Lake City, Utah; died at his home in Avondale, Cincinnati, September 4, from heart disease, aged 41.

Letitia Wiseman, M.D. Gross Medical College, Denver, 1900; of Cheyenne, Wyo.; a fellow of the American Medical Association; died in Denver, September 21, from tuberculosis, aged 49.

John C. Neely, M.D. Medical College of Georgia, Augusta, 1896; a Fellow of the American Medical Association; of Bainbridge, Ga.; died in a sanatorium in Atlanta, September 19, aged 43.

Roland Davis Jones, M.D. University of Pennsylvania, Philadelphia, 1881; while driving his automobile in Upper Broadway, New York City, September 25; died from heart disease, aged 57.

Joseph Parker Corry, M.D. Bennett Medical College, Chicago, 1892; physician of Waseca County, Minnesota; died at his home in Alma City, June 1, from an overdose of chloroform, aged 55.

Henry Harrison Sloan, M.D. Chicago Medical College, 1869; for thirty-two years a practitioner of Chicago; a veteran of the Civil War; died at his home in Rogers Park, October 9, aged 77.

Ben M. Carr (license, Tennessee, 1889); of Knoxville, Tenn.; register of Knox County from 1878 to 1886; died in the Lincoln Memorial Hospital, Knoxville, September 2, aged 56.

Sally A. Harris, M.D. New York Medical College and Hospital for Women, New York City, 1878; formerly of White Plains, N. Y.; died at Scarsdale, N. Y., September 29, aged 87.

William Britton Shuman, M.D. Medico-Chirurgical College of Philadelphia, 1907; of Upper Strasburg, Pa.; died in his home, September 21, from nervous breakdown, aged 31.

Henry A. Smith, D.D.S. Ohio College of Dental Surgery, 1857; a Fellow of the American Medical Association; died at his home in Cincinnati, September 10, aged 80.

Harlen W. Carter, M.D. Medical College of Indiana, Indianapolis, 1880; formerly of Moline, Ill.; died in Indianapolis, Ind., September 6, from cerebral hemorrhage.

William Pierce Manaton, M.D. New York Homeopathic Medical College, New York City, 1886; died at his home in Greenport, L. I., N. Y., August 6, aged 48.

R. J. Cross (license, Texas, years of practice, 1907); for twenty years a practitioner of Ridgeway; died at his home, August 23, from nephritis, aged 57.

John C. Fahey, M.D. Jefferson Medical College, 1883; mayor of Wilmington, Del., from 1899 to 1901; died at his home in that city, September 21, aged 53.

William H. Fisher, M.D. Pulte Medical College, Cincinnati, 1876; died suddenly at his home in Minneapolis, Minn., September 22, from heart disease, aged 65.

Edna Griffin Terry, M.D. Boston University School of Medicine, 1886; who went to China as a medical missionary in 1887; died in China recently.

Melvin G. Paden, M.D. University of Louisville, 1912; died in the California Hospital, Los Angeles, Cal., September 14, from heart disease, aged 24.

Charles Weed Shepard, M.D. University of Michigan, Ann Arbor; died at his home in La Rose, Ill., October 1, from heart disease, aged 66.

L. B. Lester, M.D. Geneva (N. Y.) Medical College, 1864; died at his home in Greenville, Mich., about September 16, aged 86.

Philo L. Alden (License, Arkansas, 1903); died at his home in Osage Mills, Ark., September 12, aged 66.

Marriages

Raymond Hanger Dunn, M.D., Huntington, W. Va., to Miss Janet Thorne Alexander of Charleston-on-Kanawha, W. Va., October 9.

Arnold Grant Webb, M.D., Cincinnati, to Miss Josephine Cumisky of Waterbury, Conn., in Cincinnati, September 25.

Edmond J. Moquin, M.D., Fairwater, Wis., to Miss Donna Carmen of Columbus, Ohio, at Milwaukee, September 17.

John Joseph McArdle, M.D., Lawrence, Mass., to Miss Anna Gertrude Stone of North Andover, Mass., October 1.

Robert Wayne Richards, M.D., to Miss E. Claire Robinson, both of Philadelphia, at Smethport, Pa., September 26.

Francis Gorham Brigham, M.D., Boston, Mass., to Miss Helen Greeley McKissock of Brookline, Mass., October 1.

Charles Franklin Smith, M.D., Topton, Pa., to Miss Esther Naomi Folk of Farmington, Pa., September 25.

Adolph J. Neas, M.D., to Miss Eva Ottinger, both of Parrottsville, Tenn., at Newport, Tenn., September 23.

Francis Xavier Mulherin, M.D., Augusta, Ga., to Miss Mary Eulalia Feuger of Savannah, Ga., September 25.

Arthur Frederick McQueen, M.D., Amherst, Ohio, to Miss Wastelle A. Inks of Lorain, Ohio, September 20.

Edward Bruce Beasley, M.D., Fountain, N. C., to Miss Louise Xma Ferebee, of Shawboro, N. C., October 7.

Robert F. Elvington, M.D., Mullens, S. C., to Miss Annie Laurie Randolph of Kinston, N. C., September 10.

Delmer R. Duey, M.D., Belleville, Ill., to Miss Elsie Hamilton Huston of Troy, Mo., at St. Louis, October 1.

Guy Livingston Howe, M.D., Rochester, N. Y., to Miss Margaret Woodcock of Passaic, N. J., October 4.

Alfred W. Brown, M.D., Quincy, Mass., to Miss Caroline Maud Merrill of Amesbury, Mass., September 26.

Richard Baker Austin, Jr., M.D., Union, Miss., to Miss Jessie Morse of Tylertown, Miss., September 11.

Leigh F. Watson, M.D., Oklahoma City, Okla., to Miss Dora Lowe Watson of Fairmont, W. Va., September 15.

Harry Anthony Keenan, M.D., Stoughton, Wis., to Miss Martha Wilson of Edgerton, Wis., September 24.

Joseph Thomas Slattery, M.D., to Miss Anna Elizabeth McMeer, both of Dunlap, Iowa, September 16.

Isaac N. Kelly, M.D., Nespelem, Wash., to Miss Jenny Olive Easts, of Moscow, Ida., September 24.

Walter W. Held, M.D., Huntington, W. Va., to Miss Lois Jean Goodrich of Kansas City, Mo., recently.

Elvin Otis Brown, M.D., Kellerville, Ill., to Miss Lena Felters, at Griggsville, Ill., September 19.

William Kelley Hale, M.D., Wilmington, Ohio, to Miss Dessa C. Raydure of St. Louis, October 8.

Charles L. Hunsucker, M.D., Drexel, N. C., to Miss Fleta Moore of Hickory, N. C., September 30.

Roscoe Samuel Van Pelt, M.D., Malden, Wash., to Miss Edna Oglesby of York, Neb., October 1.

Grover C. Pritchett, M.D., Dana, Ind., to Miss Magdaline Hueston of Odon, Ind., September 24.

Glen E. Peters, M.D., Bloomfield, Neb., to Miss Agatha Bruner of Randolph, Neb., recently.

Carl L. Bradley, M.D., Newhall, Iowa, to Miss Iva G. Stoddard, Geneva, Iowa, October 1.

A. P. E. Schulz, M.D., St. Charles, Mo., to Miss Clara Gallagher of St. Louis, October 1.

W. R. Taylor, M.D., Milwaukie, Ore., to Miss Eunice Elton of The Dalles, Ore., September 21.

David F. Gerber, M.D., to Miss Ruth Martindale, both of Middletown, Ohio, September 24.

Aaron Denenholz, M.D., to Miss Fedora Zepler, both of New York City, September 25.

Fielding G. Carroll, M.D., to Miss Clyde Farris, both of Cave City, Ky., October 15.

Harry D. Clark, M.D., to Miss Gladys Gold at Grand Rapids, Mich., recently.

Ellis Campus, M.D., to Miss Rose Litinoff, both of New York City, August 30.

Duty of Physician to Report Diseases.—The physician is engaged in a work which places him in a position of especial and peculiar responsibility to the community, a work which carries with it moral and usually statutory obligations, on the proper fulfilment of which depends to a large degree the ability of the health department to perform its functions. The requiring of those desiring to practice to pass an examination and to be duly licensed and registered is a partial recognition of this, and presumably such licenses are given on the assumption that the recipient will comply with the requirements imposed on physicians by law, among which is invariably the duty of reporting cases of certain diseases coming to his knowledge. The physician who does not comply with such statutes not only places himself in the class of those who violate the law, but also shows himself indifferent to his moral obligations as they affect the welfare of the community. It would be well to give more definite recognition to the relationship the physician holds to the health department and to the community. Such recognition would undoubtedly be agreeable to physicians and bring them into closer cooperation with the health authorities in whose jurisdictions they practice.—Trask in *Pub. Health Rep.*

MEDICAL JOURNALS AND THE GREAT AMERICAN FRAUD

How the Medical Times Aids and Abets Quackery, with the Moral Support of Members of the Medical Profession

Two letters have been received, both from physicians. One comes from New York City and the other from Alexandria, Va. Each letter contained an advertisement of the Kellam Hospital, Richmond, Va., cut from the *Medical Times*. Here is the New York letter:

> "*To the Editor:*—I am enclosing an advertisement clipped from the *Medical Times*. It seemed to me an especially flagrant example of what may happen in the absence of proper supervision of the advertising pages of a medical magazine. The condition would seem all the worse in this instance as among the 'Board of Contributing Editors' are listed men like Howard Lilienthal of New York and Almuth C. Vandiver, who is Counsel for the Medical Society of the County of New York. The *Medical Times* is sent to two of the physicians who live at this address without charge and without solicitation. Many advertisements of proprietary preparations are inserted in type indistinguishable from that of the body of the magazine and it is of course possible that its financial backing comes entirely from the manufacturers of these drugs."

And this is from Virginia:

> "*To the Editor:*—The statements made in the advertisement of the Kellam Hospital in the October number of the *Medical Times* are so out of the ordinary that I ask you to tell us something if you can of their institution and its methods of cure. Can such things as are stated in this advertisement be true? 'Physicians Treated Free?' 'Endorsed by the Senate and Legislature of Virginia?' What can all this mean to the sufferer from cancer? If true, let the whole world of sufferers know the glorious news."

Genito-Urin Diseases

CANCER CURED AT THE KELLAM HOSPITAL

The record of the Kellam Hospital is without parallel in history, having cured to stay cured permanently without the use of the Knife, Acids or X Ray, over 90 per cent of the many hundreds of sufferers from Cancer which it has treated during the past eighteen years.

We have been endorsed by the Senate and Legislature of Virginia.

Physicians Treated Free

KELLAM HOSPITAL

WRITE FOR LITERATURE 1617 W. Main St. RICHMOND, VA.

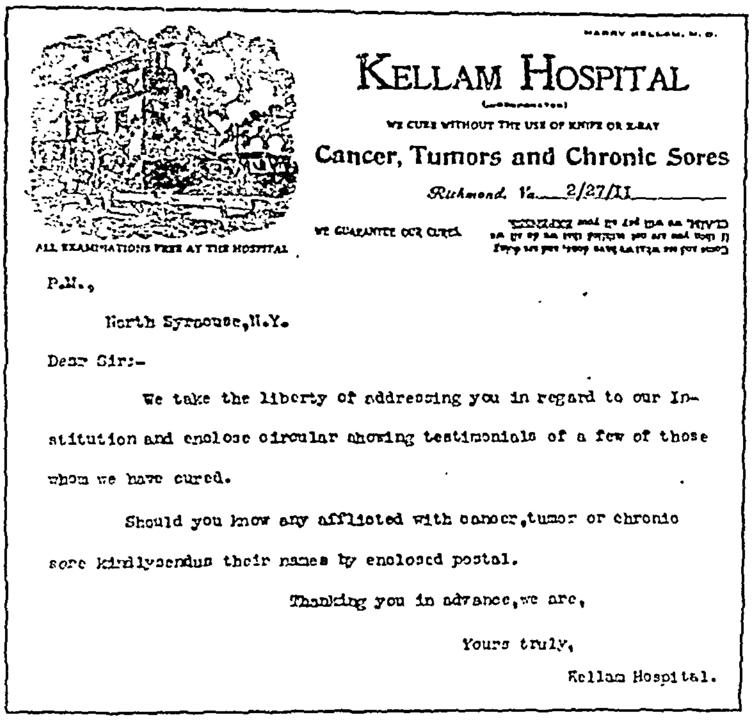
Fig. 1.—Photographic reproductions from the *Medical Times*. Do the gentlemen whose names appear in the list of the "Board of Contributing Editors" realize that they are lending an air of respectability to an otherwise disreputable business?

Collier's paid its respects to the Kellam concern some time ago and we cannot do better than quote from its pages. Thus:

"Grief is the portion of the Kellam Cancer Hospital, of Richmond, Virginia, because in these editorials it has been grouped with other exemplars of the Great American Fraud. It offers the invariable and hollow mockery of testimonials and endorsements, which, as has been repeatedly shown, can be wheedled, browbeaten or bribed out of the victims of any form of quackery. It, of course, courts the fullest investigation, and desires that we send a representative to *investigate* whether its claims are not well founded. Unsuspected by the Messrs. Kellam, our representative has already investigated their claims, notably their statement that they are endorsed by the Legislature of the State of Virginia. Upon request for a copy of the endorsement they forwarded a weak subterfuge, and finally, on pressure, admitted that they could not produce the proof they had boasted. For their further consideration we present a brief parallel:

FROM THE KELLAM CIRCULAR	FROM A KELLAM LETTER
The Cancer is *removed* without the use of the knife or X-Ray . . . No roots or fibers left; *hence it can not return.*	We do not claim to *"cure them all."* We go further, and on our part we agree to treat, free of charge, any patient *who suffers a recurrence after having been treated by our method.*

"The italics are our own, but we cheerfully present them for elucidation to the Kellam Hospital. A little careful thought devoted to reconciling the irreconcilable may help them to forget their wo. Meanwhile, they make themselves out worse than they really are by pretending to withhold from the bitter need of humanity a true, non-surgical cure for cancer. If this were true; if, indeed, they had solved the problem which has baffled the greatest minds of modern science; if, having a genuine cure for the dreadful ailment which claims its increasing thousands of tortured victims yearly, they secrete their discovery for the sake of a few paltry dollars, then they are as cold-hearted as the sailors who pass within fair hail of the naked island on which some shipwrecked crew is starving, and keep their stony eyes on the compass. They have not even the excuse of the fanatical among the Christian Scientists who, denying the existence of pain, refuse to take measures to ease the cancer victim's suffering even at the last. Human nature is seldom so callous."



HARRY KELLAM, M. D.

KELLAM HOSPITAL

WE CURE WITHOUT THE USE OF KNIFE OR X-RAY

Cancer, Tumors and Chronic Sores

ALL EXAMINATIONS FREE AT THE HOSPITAL

WE GUARANTEE OUR CURES

Richmond, Va. 2/27/11

P.M.,

North Syracuse,N.Y.

Dear Sir:-

We take the liberty of addressing you in regard to our Institution and enclose circular showing testimonials of a few of those whom we have cured.

Should you know any afflicted with cancer,tumor or chronic sore kindlysendus their names by enclosed postal.

Thanking you in advance,we are,

Yours truly,

Kellam Hospital.

Fig. 2.—One way of drumming up trade in the "cancer cure" business! The Kellam Hospital sends letters like this to the postmasters of small towns asking these government officials to furnish it with what, in the parlance of quackery, is known as a "sucker list." A delightful business, isn't it? And this, gentlemen of the "Board of Contributing Editors," is the sort of thing to which you are lending your influence and good names!

As for the *Medical Times:* This publication for years contained comparatively little advertising. Then it came into the hands of Romaine Pierson, who also owns the *Practical Druggist.* Mr. Pierson is not a physician and to him the medical profession is but a commercial problem. He is publishing a medical journal for the money there is in it, and for this he is not to be censured. Questions of advertising policy, in such circumstances, are determined on a commercial basis. When an advertising contract is submitted, for a product that physicians would know to be fraudulent, the question that arises is, "Can it be put over?" Manifestly, a medical journal published purely as a business venture would not dare long to fly in the face of the opinions of those from whom it received its support—its subscribers and contributors. If our correspondents will go through the advertising columns of the *Medical Times* they will find many, many other frauds, less cruel perhaps than the Kellam advertisement, but no less disreputable or discreditable to the medical profession.

After all is said and done, it is enlightened public opinion that is causing publishers of lay magazines and newspapers to eliminate fraudulent "patent medicine" and quack advertisements. Until the medical profession takes an equally enlightened stand, physicians may expect to be inflicted with such commercial medical journals as the *Medical Times*, the *International Journal of Surgery*, the *American Journal of Surgery*, *American Medicine*, and several other papers that are published primarily in the interest of the advertiser. When such journals as these find they cannot get a circulation among physicians so long as they carry advertisements similar to many now appearing in their pages, these advertisements will be eliminated, but not before. Many physicians are receiving such journals at a nominal price or, as one of our correspondents notes, free. The physician who permits such journals to come to his office must share with the paid subscribers the responsibility for the low standard of medical journalism.

THE ETHICS OF MEDICAL JOURNALISM

Two Physicians Express Themselves on This Subject

After the preceding article was in type, we received, in the same mail, two letters that are so apropos that we reproduce them. The first was from a town in Illinois, and was dated October 11. Here it is:

To the Editor:—About two weeks ago, a representative of the Surgery Publishing Company, New York, N. Y., came to ——— Ill. soliciting subscriptions for the *American Journal of Surgery.* Together with numerous others I subscribed —chiefly on the strength of the contributors whose articles appeared in the sample numbers shown by the agent.

Since receiving the first number (October) one look at the advertising pages has shown me why the subscription price for a year and a quarter is one dollar. Anasarcin, Tongaline, Cactina Pillets, Hagee's Cordial of Ext. Cod Liver, Burnham's Soluble Iodin, Papine, Phenalgine, Anusol, etc., etc.

I have written to the Surgery Publishing Company, telling them in no uncertain language that there is no room on my reading desk for such. Have you ever exposed this journal, and the attitude of our big, brilliant, eminent men in permitting their articles—presumably original—to fill space in such a journal? [Yes! The Journal, Dec. 16, 1911, pp. 2,000 and 2,013.] This letter is not for publication—at least not with name or city. Keep up the good work. . . .

The other, dated October 10, follows:

To the Editor:—That little story about medical journal advertising and methods of obtaining paid-up subscribers, in this week's Journal, makes me blush. I am guilty. Unlike Dr. Genella, I swallowed the bait—but the bait was even more tempting in my case; the flattering "editor" offered me twenty-five subscriptions to distribute among my friends, all for an "abstract." Thank goodness, I only accepted five subscriptions, but worse luck, I sent them to young men by preference. So I am a deep-dyed offender indeed. Extenuating circumstances affected my susceptibility somewhat, however. I have noticed that prominent men like Beverly Robinson, A. Rose, Tom A. Williams, Wayne Babcock, and Morris —the latter, at least, a really able man and a brilliant writer —contribute to these peanut journals occasionally. If they do, why not I? There's nothing like being in big company, you know.

So far as I know, my "abstract" has not yet been published. On looking over the sample copy of this monthly I found an advertisement printed right in the list of contents—in fact, it was the second "original article" in the issue, as brave and respectable as you please! Then, with characteristic Hibernian impetuosity I got out my machine and pounded that editor a strong protest with a dire command not to use my "abstract" in his miserable organ. But I have never received the manuscript, nor any reply to my stern rebuke. I wish I had been cautious like Dr. Genella.

Wm. Brady, M.D., Elmira, N. Y.

Correspondence

Simple Method of Sterilizing Rubber Gloves

To the Editor:—For the past three years I have been using a simplified method of preparing my rubber gloves by which they are rendered sterile and, at the same time, given a coating of talcum, making them easy to adjust. In my hands this method has proved eminently satisfactory, and while some theoretical objections may be raised as regards the completeness of the sterility, results in about three hundred cases have shown absolute safety. My reason for giving this method is that many physicians fail to use rubber gloves in their obstetric work, at least as a routine measure, simply because of the rather laborious methods used in their preparation. My method is as follows:

An 8-ounce bottle is half filled with talc, to which has been added 2 tablets of mercuric cyanid. The bottle is then filled with 90 per cent. alcohol. This solution is constantly kept on hand in the office. The used gloves are merely washed in hot water, rinsed, placed in a sterile dish and the well-shaken solution poured over them. They are then removed and placed on a sterile towel to dry. The evaporation of the alcohol leaves the gloves completely covered with the dry talc-cyanid powder. They are then wrapped in the towel and placed in the obstetric satchel, while the left-over solution is returned to its original bottle. Gloves prepared in this way have been used by me in cases requiring version, removal of adherent placenta, manual dilatations, etc., and as yet I have never had a case showing septic symptoms of any kind.

Ray Ernest Smith, M.D., Rutland, Vt.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TEST FOR CARBON MONOXID IN THE ATMOSPHERE

To the Editor:—Please give me test for carbon monoxid (CO) in the atmosphere. E. Caster, Solomons, Md.

Answer.—*Boettger's Test.*—Paper moistened with palladium chlorid solution (0.0002 gm. in 100 c.c.) becomes darkened in the presence of carbon monoxid.

Dejust Method.—This method depends on the reducing action of carbon monoxid on a weak ammoniacal silver solution. If air containing carbon monoxid be passed through an ammoniacal silver solution, metallic silver will be precipitated and, according to the amount of the latter, the solution takes on a brown or black color. While the change in color of the solution may be used as a qualitative test for carbon monoxid, Dejust uses the reaction for the quantitative determination as follows: 20 c.c. of 1 per cent. ammoniacal silver nitrate solution are allowed to drop through the air from a funnel the stem of which has been drawn out to a fine point, so that the liquid will require one hour to pass through. The end of the funnel is so arranged that the drop falls through a few centimeters of air to a dish. The liquid having run through is returned to the funnel and allowed to run through three more times. The color of the solution is then compared with silver solutions which have been allowed to act on air containing carbon monoxid 1:1,000, 1:5,000, and 1:10,000. (*Chem. Centralbl.*, 1905, ii, 21, from *Compt. rend. Acad. d. sc.*, cxl, 1250.)

Blood Test.—Most commonly the reducing action on blood is used for the detection and estimation of carbon monoxid. Qualitatively the presence of carbon monoxid in air may be recognized by the change in color when water to which has been added a drop of blood is treated with the air to be tested for carbon monoxid. While a dilute blood solution is yellow, it becomes pink when treated with traces of carbon monoxid. More accurately the test is carried out with the aid of a spectroscope as follows: To the sample of air collected in a jar pure water is added, and into this a drop or two of blood from a pricked finger is made to fall, so as to make a dilution of about 1 in 300. This diluted blood is next well shaken up with the air in the jar, and then a small quantity is placed in a spectroscope, for an examination of its absorption bands. As so examined, the appearance in the spectrum will closely approximate to that of oxyhemoglobin. Oxidized hemoglobin shows two well-marked bands in the yellow and in the green parts of the spectrum, both lying between D and E; a little ammonium sulphid is now added and the bottle well shaken; if carbon monoxid is present the spectrum will undergo no change, but if absent, the ammonium sulphid will reduce the hemoglobin, as indicated by a single absorption band in the spectrum occupying an intermediate position with regard to the two original bands. (J. L. Notter: "Treatise on Hygiene," Ed. 2, p. 195.)

LITERATURE ON RADIUM

To the Editor:—Please refer me to books or medical journals giving information on the subject of radium.

W. S. Butterbaugh, M.D., Westcliffe, Colo.

DID SYLLA HAVE A PARASITIC DISEASE?

To the Editor:—Below I quote from "Plutarch's Lives" an incident in the life of Sylla (often written Sulla), and I am curious to know just what the parasite was that tormented his latter days. As this old soldier had courtesans and dissolute persons in plentiful numbers for his companions, it is possible that he had syphilitic ulceration of the anal region and that this had become infested with maggots, though I have not been able to find that the word "louse" which Plutarch uses meant other than our familiar *Pediculus capitis* or *P. vestimenti.* As Sylla "lost a great quantity of blood" there is the probability of malignancy of the rectum with ulceration and fatal hemorrhage, but that still does not explain the character of the parasites which the historian calls "lice."

"Notwithstanding this marriage, he kept company with actresses, musicians and dancers, drinking with them on couches night and day. His chief favorites were Roscius the comedian, Sorex the arch mime and Metrobius the player, for whom, though past his prime, he still professed a passionate fondness. By these courses he encouraged a disease which had begun from unimportant cause; and for a long time he failed to observe that his bowels were ulcerated, *till at length the corrupted flesh broke out into lice.* Many were employed night and day destroying them, but the work so multiplied under their hands that not only his clothes, baths and basins, but his very meat was polluted with that flux and contagion, they came swarming out in such numbers. He went frequently by day to scour and cleanse his body, but all in vain; the evil generated too rapidly and too abundantly for any ablutions to overcome it. There died of this disease among those of the most ancient times, Acastus, the son of Pelias; of later date, Alcman the poet, Pherecydes the theologian, as also Mucius the lawyer; and if we may mention ignoble, but notorious names, Eunius the fugitive, who stirred up the slaves of Sicily to rebel against their masters, after he was brought captive to Rome, died of this creeping sickness."

Then follow some interesting incidents in the closing days of this remarkable man, conferences with various officials with whom he had been associated in the affairs of government, and the strangling of Granius, which he caused to be done in his presence. The narrative closes with the statement that "through the straining of his voice and body, the imposthume (abscess) breaking, he lost a great quantity of blood. On this, his strength failing him, after spending a troublesome night, he died."

Fayette Dunlap, M.D., Danville, Ky.

Answer.—Stewart and Long, in their translation of Plutarch (London, Bell & Co., Bohn), suggest that Plutarch is here adopting a popular tradition circulated by Sylla's enemies. No other historian mentions it. Appian in his "Civil Wars," Volume I, says "Sylla died in his sixtieth year the most fortunate of men in his end and in everything else, both in name and estimation, if, indeed, a man should think it good to have obtained all his wishes."

What the condition that preceded his death was is hard to say. Tuberculosis seems not unlikely, for death was immediately preceded by "the bursting of an imposthume followed by the vomiting of a quantity of blood." There had been a lingering disease. Sylla knew that his end was approaching, and lung and rectal troubles, both tuberculous, occur together often enough to make this seem probable. The Greek word used by Plutarch for the living things engendered in the wound is φθεῖρες, lice, from which our phthiriasis. Popularly it was believed that these could be spontaneously generated in dirty disease conditions, but no medical writer asserts any such thing. Plutarch probably accepted a current tradition in order to point the moral of vice finding its own punishment in most deterrent results. He was the original propagator of information as to the physical results of vicious living, and exhibits often the tendency to exaggeration of the muck-raker at all times.

HYPODERMIC ADMINISTRATION OF IRON

To the Editor:—In administering iron hypodermically:

1. What preparation is used?
2. What is the dosage?
3. Are the injections only subcutaneous or deep?
4. How often repeated?
5. Are the results generally good and is there any advantage over the oral method?

H. R. Parker, M.D., Lunbar, Pa.

Answer.—1. Iron and ammonium citrate has been used for this purpose.

2. The dose is 0.13 gm. or 2 grains; in children ¾ grain.

3. The injections should be intramuscular.

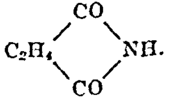
4. It is recommended to give the remedy every other day.

5. It is asserted that the results are more marked and are obtained more rapidly than when iron is given by the mouth, and that there is much less danger of disturbing the digestion. The method may in rare cases be of service, but in the majority of cases sufficient iron can be given by mouth without producing gastric irritation.

WEICHARDT'S ANTIKENOTOXIN

To the Editor:—Concerning the query, "What is Weichardt's Antikenotoxin?" (The Journal, Sept. 27, 1913, p. 1059), the following might be of interest:

Weichardt calls "antikenotoxin" (*retardive Hemmungskoerper*) a group of substances which inhibit the action of the fatigue-poisons called "kenotoxin." The latter are formed in the body during muscular exercise. The former arise when kenotoxin is formed or injected into the body, and they can be isolated from the blood-serum in a comparatively pure state. This is effected by dialyzing, as they pass through the membrane; the dialysate-water is evaporated and they are extracted from the residue with toluol or acetone. These substances, or others with a similar action, can also be prepared *in vitro* from protein. One of the preparations, although probably not one of the most active, could be purified by recrystallization and proved to be:



For further details, technic and literature see "Ueber Ermüdungsstoffe," by Dr. Wolfgang Weichardt, Stuttgart, Verlag von Ferdinand Enke, ed. 2, 1912, price, 2 marks.

F. W. L. Tydeman, M.D., Charlotte, N. C.

PINAUD'S EAU DE QUININE

To the Editor:—Kindly give me the formula of Ed. Pinaud's "Eau de Quinine." W. C. Mayes, Memphis, Tenn.

Answer.—Pinaud's Eau de Quinine appears to be a nondescript mixture of alcohol and water scented and colored, and containing a trace of quinin. The following statement is translated from "Hahn-Holfert-Arends Spezialitäten und Geheimmittel," sixth edition:

"Pinaud's Eau de Quinine contains neither quinin nor any other cinchona alkaloids, nor any other characteristic constituents of cinchona bark; the preparation is also devoid of salts of metals, tannin, salicylic acid and cantharides (Tscheppe)."

The following statement from "Thesaurus of Proprietary Preparations," by [illegible] E. Hiss, 1899, also probably refers to the Pinaud preparation:

"In a suit in the U. S. Circuit Court at Boston concerning its tariff classification, the court was satisfied 'that this article contains of absolute alcohol substantially 67 per cent. by volume; that the solid residuum, amounting to about 18/100 of 1 per cent., consists principally of an odoriferous resin having a fragrance similar to that of benzoin; a minute trace of quinin sulphate, and also a very small percentage of essential oils, the remainder being water.'"

The following formula is stated to yield a similar preparation:

"Alcohol	fl. oz.	10
Water	fl. oz.	5½
Yellow cinchona	av. oz.	½
Cochineal	gr.	30
Potassium carbonate	gr.	30
Tincture of benzoin	fl. dr.	2
Oil of bergamot	drops	30
Oil of sweet orange	drops	30
Oil of rose geranium	drops	10"

The American Medical Association Chemical Laboratory was asked to examine the preparation to determine the presence or absence of quinin. The following is the chemists' report:

"A specimen of Eau de Quinine recently purchased had a decided red color and a flavor like hair-oil. It contained alcohol and water, but appeared devoid of any appreciable quantities of glycerin or fatty oils. It did not respond to tests for methyl (wood) alcohol. The ethyl alcohol content was approximately 66 per cent. (by the provisional method of Association of Official Agricultural Chemists, Bur. Chem. Bull. 107, p. 83). The alcohol from 100 c.c. having been removed by distillation, the residue was made alkaline and extracted with chloroform. The chloroformic extractions were then extracted with acidulated water and the acid solution rendered alkaline and extracted with chloroform. On evaporation of the chloroform 0.0226 gm. of residue was obtained, which responded to the tests for quinin. From this it appears that Eau de Quinine contains about 0.02 per cent. of quinin or cinchona alkaloids."

From this examination it is seen that while at one time the addition of quinin to Pinaud's Eau de Quinine may have been considered unnecessary and useless, at the present time the preparation does contain a minute trace of quinin—just enough, perhaps, to escape prosecution under the federal Food and Drugs Act for misbranding.

LITERATURE ON SEWAGE DISPOSAL

To the Editor:—Please give me some information or refer me to literature on the building for hotel use of an inside toilet-room and proper disposition of sewage in a small town without sewers or city water-works. Cecil C. Smith, Stanton, N. D.

Answer.—It is not quite clear from our correspondent's letter whether water from tanks for flushing is available or whether the disposition of the sewage must be carried out by the dry method. If the latter, a new and recommended form of sanitary privy is described in *Public Health Reports* for July 25, 1913. In case modern sanitary plumbing can be used, a good description of disposal plants for isolated residences will be found in the *Bulletin of the Ohio State Board of Health* for July, 1911. This matter is also discussed in "Sewage Disposal," by George W. Fuller, McGraw-Hill Book Company, New York, 1912.

CORRECTION AS TO METHOD OF USING WRIGHT'S STAIN

To the Editor:—Slips are exceedingly rare in your excellent journal—in my opinion the best published in the English language; but I note that on page 1315, Oct. 4, 1913, you state, in answering a query regarding Wright's stain, that "specimen smears should be fixed before using" the stain. One of the great advantages of the method is, on the contrary, that it does not require a preliminary fixation of the preparation. The rest of the directions are correct.

X. Y. Z.

Answer.—This correction has been called to our attention by several others. Wright's stain contains methyl alcohol, which acts as a fixative. Heat is not necessary.

ALCOLA

To the Editor:—Can you give me information as to the composition and worth of Alcola, a "cure" for alcoholism, exploited by the Physician's Cooperative Association of Chicago?

Ralph H. Hertzler, M.D., Newton, Kan.

Answer.—Alcola is the same kind of fake as the rest of the mail-order liquor "cures." The Journal publishes a pamphlet ("Alcola," price 4 cents) on this preparation which answers our correspondent's question as to the standing of the Physician's Cooperative Association of Chicago and the value of the treatment.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POST-GRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

NEWSPAPER COMMENTS ON SEX HYGIENE

One of the questions at present exciting general interest among laymen is that of sex hygiene and the advisability of instructing children and young persons therein. Naturally the discussion rages most fiercely around the question of instruction in sex hygiene in the public schools. Many interesting opinions have been expressed by the newspapers of the country. The judicial thinker must recognize that this question as yet is still in suspense. There is not any unanimity of opinion or agreement on fundamentals sufficient to justify the candid and conservative observer in taking any definite position. Yet the discussion going on through the magazines and newspapers is of the greatest value in bringing to light different sides of the question, and in arousing public interest in the acquisition of more accurate knowledge of these vital subjects.

Stripped of all non-essentials, there are really three questions under discussion. These are:

1. Should children and young persons of preadult ages be instructed in sex hygiene?

2. If so, through what agency should this instruction come? Should it be through one or both parents, through a religious medium, through the public schools, or through books, pamphlets and leaflets of an impersonal character?

3. If it is decided that instruction on this subject should be given in the public schools, what is the best form in which it can be presented to the youthful mind?

Even the most superficial will admit that these three questions present many problems of the utmost complexity. It is difficult to see how any one animated by a calm, judicial spirit can take any other position than that of suspended judgment on the entire question at present. Whatever one may think of the advisability or desirability of sex hygiene instruction in the abstract, one is reminded of Captain Cuttle's famous saying, "The value of the observation lies in the application of it." The test of any scheme of instruction in sex hygiene is going to lie in the manner in which it is carried out, and in the tact, good judgment and common sense of the persons doing the teaching, whether they be parents, religious teachers, schoolteachers or writers.

The reflection of opinions on the part of the newspaper editors is interesting as showing the diversity of views expressed.

The Seattle (Wash.) *Post-Intelligencer*, commenting on the objections of the local superintendent of schools, says, "That sex hygiene is a matter for the future is too probable to admit of much doubt, but just now such instruction is decidedly impracticable . . . Before any such revolutionary change in the general notions of sex matters as is implied in the teaching of sex hygiene can be made, the vast body of public opinion must be attuned to it and made to recognize its necessity, not through controversy, but through intelligent appreciation of certain facts. To this end the present discussion for and against eugenics, foolish as it often is on both sides of the argument, is working. That the fundamental physical problems of life, once rigorously taboo, are now permissible topics for conversation is a sure index of the direction in which we are going."

The *Post-Intelligencer* takes a sound view of the value of present discussion, without in any way yielding its judgment as to its ultimate opinion. It is also perfectly sound in holding that the question "will solve itself gradually and quietly within the next generation, and the desired end will be attained at far less cost and with far more speed if it is not hampered with overanxiety for immediate results."

The Waterloo (Iowa) *Courier*, starting out with the proposition that "health is the foundation on which rests the happiness of a people and the power of a nation," lays particular stress on the necessity of public-school education in hygiene and sanitation. After elaborating an extensive program for public-school education, it says, "The health movement in our public schools has been transformed during the past decade from a purely negative movement, having as an object the avoidance of disease, to a splendidly positive movement, having for its aim the development of vitality." While the subject of sex hygiene is not specifically included in the *Courier* program, it evidently assumes that this will follow. "In these schools the physical, the mental and the moral will be developed together and not separately."

The Beloit (Wis.) *News* states that "wide difference of opinion still exists among schoolmen on this subject, although they are united in recognizing what President Foster of Reed College calls 'the social emergency,' the separation coming when the details of the exact part the public schools shall play in this campaign are taken up." After discussing the opinions of various educators, the *News* concludes that this question is assuming increasing importance in our school system, and that some practical solution for the problems involved will have to be devised.

The Fort Worth (Tex.) *Record* "seriously doubts the wisdom of any attempt of education in the public schools on this delicate question." It regards the subject as one of such sacredness that it should not be allowed to become a topic of careless and common conversation among the bold and irreverent Young Americas that constitute the school population. In the opinion of the *Record*, the proper teachers on such subjects are the fathers, mothers and family physicians. "The modern tendency to put all responsibilities of instruction on schoolteachers is dangerous in the extreme . . . The public school cannot take the place of the home or the church." While the *Record* recognizes the fact that "there are children without intelligent or watchful parents and without religious surroundings, and that these exceptions deserve consideration," it is of the opinion that a great mass of children in the United States come from proper homes and have no need of tuition in morals in the public schools. "Let the home, the physician and the church bear their own responsibilities in rearing the rising generation," is its final conclusion.

The Chicago *Record-Herald*, discussing the bulletin of the federal Bureau of Education on this subject, and the conflicting views expressed therein, finds nothing strange or unusual in this divergence of opinion. "The learned doctors never agree, and if society waited for unanimous consent of the experts nothing would ever be done. Questions are settled by experience, not by disputation." The *Record-Herald's* views on the outcome of reform movements and controversies are especially interesting. "Questions are forgotten, not settled. Unconvinced parties give up and take up new issues." The editor's application of this philosophy to the problem of sex hygiene is that sex hygiene as a course of study is undoubtedly coming in this country. The really significant fact is that so many educators, social workers, physicians and moralists have been converted to the idea in such a short space of time. The results it is willing to leave to the future.

The Wilkes-Barre (Penn.) *Record* asks, "Should sexology be introduced into the schools as a study or by way of a series of lectures?" After stating the arguments on both sides, the *Record* concludes, "We believe the weight of the argument is in favor of those who advocate a simple form in instruction for children who have reached the last year or two of grammar school." Believing that the amazing amount of evil from vice is the result of ignorance, the *Record* favors instruction which would "follow up the laws of Nature as revealed in plant life and animal life, so as to be without the element of harmful suggestiveness." Drawing a comparison between the evils done by intemperance and those caused by sexual vices, the editor concludes, "More can be done in the way of abstention from alcoholic indulgence by impressing young people with the astonishing physical consequences than in any other way, and so it is with the almost incredible consequences of sexual dissipation."

Probably no newspaper in New England is more ably edited or exercises a wider influence than the Boston *Transcript*. Its editorial point of view is sane and conservative. Its opinion is that "although educators and physicians have not yet agreed as to whether sex hygiene should be taught in the public schools, or how it should be taught if at all, it must be admitted that the whole question of sex education is assuming great importance in our city school systems."

The Philadelphia *Ledger*, on the other hand, regards the present agitation as a passing fad. "The zeal of the advocates of the proposed change is analogous to the zeal of the ultraprogressives who would reform the world by legislation." The *Ledger's* criticism of advocates of radical legislation for which no public support has been developed is thoroughly sound. "To such persons, an act placed on the statute books seems the end of positive effort for the betterment of the world. This secured, vigilance subsides and the honest-motived but ill-directed reformer settles down to a complacent satisfaction." While this is true of many reformers and agitators who seek to accomplish moral ends by legislation, it can hardly be applied with fairness to those advocating education and instruction as a means of influencing action. The *Ledger's* question, "Why should any adult impose his alarmist instruction on the youth?" is easily answered. It is because the adult has seen enough of the results of youthful folly to justify his alarm and to lead him to guard the youth from repeating and perpetuating the mistakes of previous generations. This is the only reason why adults are teachers and why youths are pupils. Age has accumulated knowledge and experience which it would hand down to youth. Summing up its argument, the *Ledger* decides that public schools do not need a course of sex hygiene. "They may need a healthier-minded attitude on the part of all teachers of biology, hygiene and physical instruction." In the opinion of the *Ledger*, the teachers opposing sex hygiene instruction have a more correct attitude of mind toward their subject than have the advocates of the plan, which the *Ledger* regards as a course "full of peril and demoralizing possibilities."

In addition to its editorial, the *Ledger* gives space to a number of letters discussing both sides of the question. One correspondent, while admitting that "the proposed new teaching is not without danger," hopes that eventually the letting in of light on this subject "will lead up to that happy condition when there will be no more nasty prudery about describing sex to mixed classes than there is now in describing the stamens and pistils of flowers." The correspondent rather cleverly attempts to spike the guns of the *Ledger's* editorial by quoting from an editorial which appeared in the next column on "Degeneracy in a Little Town," in which the repulsive conditions found in a Newfoundland village are described, with the editorial comment that "the difficulty seems to be that these people are content to be no better than their fathers were before them." While admiring the correspondent's ingenuity, it must be admitted that he is begging the question, since the point which the *Ledger* is discussing is whether such a course would make the children better than their fathers. Another correspondent takes the opposite side of the question, quoting Plato, Emerson, Rousseau and Herbert Spencer in support of his proposition that "the teaching of this delicate subject is for the parents, the church and the doctor."

The Chicago *Tribune* sums up the question in this fashion: "It is not a question of whether the youth shall remain ignorant or be instructed. It is a question whether it shall be well or ill instructed."

Collier's Weekly holds that "the argument for teaching sex hygiene is being cried in agonies. . . . The sob of a mother whose baby must go through life blind because of some one's ignorance is an argument for sex education that defies the glibbest debater."

Especially important as showing the probable attitude of the Roman Catholic Church on this question is an editorial in *America*, which designates the proposition to teach sex hygiene in the public schools as "the newest and most dangerous of all the educational fads now being daily foisted on us." The argument of *America* is for development of character in the public schools, rather than for an increase in detailed instructions in facts. "It is not the law of the mind that needs strengthening, but the law of the members that needs restraining; not more knowledge but more will is required." One kind of instruction in sex hygiene would meet the approval of *America*. "Instead of being worried about increasing the knowledge, be energetic and persistent in decreasing the desire. . . . It is the incentive that should be removed." The way to better conditions lies, in the judgment of *America*, in improving social conditions rather than in specific instruction of schoolchildren. "Let the sex hygienists put away the countless seductions which assail mankind and womankind on all sides, and they will effect something. Let the young have less desire, not more knowledge; strength of will, not complete information."

While recognizing the necessity of developing personal character and will power, as well as the uselessness of increasing knowledge without developing personal qualifications to correspond, *America's* argument is weak, in that it objects to a specific method of instruction and offers instead a vague general plan of reform. Doubtless, the sex hygienist would be glad to "put away the countless seductions which assail mankind and womankind on all sides." But how is such a stupendous task to be accomplished? To object to proper instruction in the public schools, and offer as a substitute a reform of newspapers, theaters, fashions, current fiction and habits of living hardly seems to be a practical criticism.

The Los Angeles *Graphic* thinks that such instruction is a duty of parents, but that 90 per cent. of American parents "dodge the responsibility of instructing their children properly in sex matters."

A correspondent of the New York *Independent* denounces the idea as "the most vicious of all the wild, indiscreet and dangerous suggestions made in behalf of the human race." The *Independent* correspondent is a true optimist. He says, "The world is growing better all the time and will continue if let alone on such subjects as this." If this is true, the pathway to the millennium is a straight and easy one.

In a multitude of counselors there may be safety; but with the safety is combined great diversity of opinion. What conclusion can be drawn from this discussion, which has evidently only just begun? None, at present, except that the need of adopting some plan by which the disastrous effect of social evils can be diminished is apparently admitted by all. The discussion then turns on the important questions of when, where and how. Where shall the child be instructed: at home, in the church or in the school? If the Los Angeles *Graphic* is correct and if 90 per cent. of American parents are dodging their duty, then one of two courses must be adopted. Either parents must be educated to a realization of their responsibility, or some other agency must take the place of the parent in education on this subject. If a substitute for the parent must be found, which shall it be, the church or the public school? If the church, to-day, using this term in its broadest and most comprehensive sense, were attracting or holding the greater part of our population, and if a majority of the children of public-school age were coming under the influence of the church, this might be considered as an ideal arrangement. But what are the facts? We have in most states compulsory school laws. We have not nor can we have any compulsory church laws. Only those who desire church relations come under religious influences. The most liberal estimate, accepting the figures of the churches themselves, shows that only 35,000,000 out of our total population of about a hundred million are directly connected with any religious organization of any character. The church as educational factor in this field, therefore, would have efficiency of only about 35 per cent. If the church will unde take this responsibility for those children whom it can reac by all means let it do so. But what of the 65 per cent. ou side its influence?

So much for the answer to the first question. As to tl second and third questions, when and how, these must l settled by our authorities in psychology and practical pedagogy. Public interest in the subject is unquestioned. To repeat, it is not a matter to be settled by heated controversy but by calm and judicious consideration. Above all, it is not a matter to be controlled by the "fringe of fanatics" which, as Theodore Roosevelt has aptly said, "hang on the outskirts of every reform movement." The question is not as yet one for dogmatic assertion but for careful consideration and suspended judgment.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARKANSAS: Regular Little Rock, November 11-12. Sec., Dr. W. S. Stuart, Pine Bluff; Homeopathic, Little Rock, November 11. Sec., Dr. Ida J. Brooks, E. 10th St.; Eclectic, Little Rock, November 11. Sec., Dr. C. E. Laws, 712 Garrison Ave., Ft. Smith.

CONNECTICUT: Regular, City Hall, New Haven, November 11. Sec., Dr. Charles A. Tuttle; Homeopathic, New Haven, November 11. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave.; Eclectic, New Haven, November 11. Sec., Dr. T. S. Hodge, 19 Main St., Torrington.

FLORIDA: Jacksonville, November 12-13. Sec., Dr. J. D. Fernandez.

LOUISIANA: New Orleans, October 27-29. Sec., Dr. A. B. Brown, 24 Cusachs Building; Homeopathic, 702 Macheca Bldg., New Orleans, November 3. Sec., Dr. Edward Harper, New Orleans.

MAINE: City Hall, Portland, November 11-12. Sec., Dr. Frank W. Searle, 776 Congress St.

MISSISSIPPI: Jackson, October 28-29. Sec., Dr. E. H. Galloway, Jackson.

NEBRASKA: Lincoln, November 12-13. Sec., Dr. H. B. Cummins, Seward.

NEVADA: Carson City, November 3. Sec., Dr. S. L. Lee, Carson City.

NEW JERSEY: State House, Trenton, October 21-22. Sec., Dr. H. G. Norton, 429 E. State Street.

SOUTH CAROLINA: Columbia, November 11. Sec., Dr. A. Earle Boozer, 1806 Hampton St.

TEXAS: Bender Hotel, Houston, November 11-13. Sec., Dr. W. L. Crosthwait, Suite 1003, Amicable Bldg., Waco.

WEST VIRGINIA: Hotel Chancellor, Parkersburg, November 10. Sec., Dr. S. L. Jepson, Wheeling.

Postgraduate Work in Medical Sciences

In order to meet the desire of physicians of New York City for opportunities to keep abreast of the advancing knowledge of the medical sciences, the directors of some of the leading laboratories in that city have cooperated to offer a series of postgraduate courses on their respective subjects. The institutions cooperating are: the College of Physicians and Surgeons of Columbia University, the University and Bellevue Hospital Medical College, the Cornell University Medical College and the Research Laboratory of the New York City Department of Health. The work is under the charge of Dr. Haven Emerson, with headquarters at 120 East Sixty-Second Street. The courses outlined consist of lectures, demonstrations and laboratory work in anatomy, physiology, chemistry, pharmacology and bacteriology.

The Federation of State Medical Boards

At a recent meeting of the Federation of State Medical Boards of the United States, Dr. James A. Duncan, formerly of the Ohio Board; Dr. Albert de Bey, formerly of the Iowa Board, and Dr. Charles A. Tisdale, formerly of the California Board, were nominated for Honorary Fellowship in the Federation.

The next annual session of the Federation was called to be held in the Francis I Room of the Congress Hotel, Chicago, Wednesday, February 25, 1914—on the day following the tenth annual conference of the Council on Medical Education.

Wisconsin June Report

Dr. John M. Beffel, secretary of the Wisconsin State Board of Medical Examiners, reports the written examination held at Milwaukee, June 24-26, 1913. The number of subjects examined in was 20; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 96, including 2 osteopaths, of whom 89 passed, including 2 osteopaths, and 7 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED

Indiana July Report

Dr. W. T. Gott, secretary of the Indiana State Board of Medical Registration and Examination, reports the written examination held at Indianapolis, July 8-10, 1913. The number of subjects examined in was 16; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 89, all of whom passed. Fifteen candidates were licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
University of Colorado	(1912)	93.5
Coll. of P. and S., Chicago (1904) 88.7;	(1913)	92.1
Chicago College of Medicine and Surgery (1912) 83.9; (1913) 85.9, 86.9, 88.5, 91.2, 93.6.		
American College of Med. and Surgery, Chicago	(1905)	78.4
Rush Medical College (1892) 84.4;	(1911)	90.8
Northwestern University	(1912)	91.5
Hahnemann Med. College, Chicago (1912) 84.2;	(1913)	85.4
Indiana University (1913) 83.3, 85.5, 85.7, 85.7, 86, 86.2, 86.4, 86.5, 86.9, 87.1, 87.2, 87.2, 87.4, 87.6, 87.8, 87.8, 88, 88.1, 88.8, 88.8, 88.8, 88.9, 89.2, 89.2, 89.3, 89.3, 89.3, 89.5, 89.6, 89.7, 90, 90.3, 90.7, 91, 91.1, 91.3, 91.6, 91.7, 92, 92.2, 92.2, 92.7, 92.7, 92.9, 93.6, 93.7, 94.		
Kentucky University	(1898)	87.7
University of Louisville (1912) 87.1; (1913) 86.7, 87.1, 87.2, 88.3, 88.4, 88.8, 89.8, 90.6, 90.8, 91.3, 91.4, 91.8, 92.8.		
Harvard Medical School	(1913)	93.3
Columbia Univ., Coll. of P. & S., N. Y.	(1890)	88
Eclectic Medical College, Cincinnati	(1913)	90.9, 92.6
Medical College of Ohio	(1901)	82.6
University of Pennsylvania	(1913)	92.1
Hahnemann Med. Coll. and Hosp., Philadelphia	(1896)	85.2

LICENSED THROUGH RECIPROCITY

College	Grad. Year.	with Reciprocity
Women's Medical College, Chicago	(1893)	Colorado
Chicago College of Medicine and Surgery	(1906)	Illinois

Bennett Medical College	(1912)	Wisconsin
University of Louisville	(1909) (1911)	Kentucky
Hospital College of Medicine, Louisville	(1910)	Tennessee
Johns Hopkins University	(1907) Maryland; (1910)	Michigan
University of Michigan, Homeo. College	(1911)	Michigan
University of Michigan, Coll. of Medicine	(1911-12)	Michigan
Long Island College Hospital, N. Y.	(1907)	Illinois
Miami Medical College	(1897) (1911)	Ohio
University of Pennsylvania	(1898)	Penna.

Colorado July Report

Dr. David A. Strickler, secretary of the Colorado State Board of Medical Examiners, reports the oral and written examination held at Denver, July 1, 1913. The number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 75. The total number of candidates examined was 34, of whom 33 passed and 1 failed. Twenty-one candidates were licensed on presentation of satisfactory credentials. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
University of Colorado	(1912) 75.5, 81.4, 84.9, 89.7; (1913)	75, 75.2, 76.1, 78.5, 79.7, 80, 80.4, 81, 81.2, 81.2, 81.5, 82.1, 82.3, 84.3, 84.7, 85.6, 85.7, 86, 86.5, 86.7, 87.3, 87.5, 88.2, 88.2, 88.8, 90.6.
Hahnemann Med. College and Hospital, Chicago	(1913)	82.5
Central Medical College, Missouri	(1900)	75.3
Woman's Medical College of Pennsylvania	(1912)	82

FAILED

Kansas Medical College	(1900)*	

LICENSED ON PRESENTATION OF SATISFACTORY CREDENTIALS

College	Year Grad.	State Licenses
Rush Medical College	(1888) 1907) (1911) Illinois; (1912)	Utah

Columbia University, College of Phys. and Surgs., N. Y.	(1896)	New York.
University of Pennsylvania	(1910) Indiana; (1910)	Penna.
Chattanooga Medical College	(1901)	Alabama

*No grade given.

West Virginia July Report

Dr. S. L. Jepson, secretary of the West Virginia State Board of Health, reports the oral, written and practical examination, held at Charleston, July 14-16, 1913. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 80. The total number of candidates examined was 45, including 3 osteopaths of whom 35 passed, including 3 osteopaths, and 10 failed. Four candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.

Book Notices

The Narcotic Drug Diseases and Allied Ailments. Pathology, Pathogenesis and Treatment. By George E. Pettey, M.D. Cloth. Price, $5 net. Pp. 516, with illustrations. Philadelphia: F. A. Davis Company, 1913.

For the most part the treatment of the narcotic drug diseases has until recently been in the hands of charlatans and quacks, who were more concerned in fleecing the victim than in curing his disease. Pettey has had long experience as a sanatorium physician in the treatment of drug addictions and is entitled to a hearing. He states that narcotic addictions belong to the field of internal medicine and not to neurology, but we are of the opinion that he who wishes to treat drug addictions successfully must be not only a good internist but also a neurologist. True to his convictions, Pettey lays great stress on the medical treatment and makes little mention of psychic treatment, which forms such a necessary part in the treatment of all forms of drug addiction. Praise is due him for giving short summaries of the physiologic action of the drugs he employs. Besides, his theoretical views on the whole are in conformity with modern medicine, though his exposition of the true pathology and pathogenesis leaves one unsatisfied. This volume will be useful to the general practitioner desirous of insight into the general subject of drug habits, about which so little has been written that is of value, and even the neurologist and sanatorium physician will gain many new points of view.

Medical Men and the Law. A Modern Treatise on the Legal Rights, Duties and Liabilities of Physicians and Surgeons. *By Hugh Emmett Culbertson, of the Ohio and New York Bars. Cloth. Price, $3 net. Pp. 325. Philadelphia: Lea & Febiger, 1913.*

There has been no time perhaps when the doctor has been held so strictly to account for what he does as the present. Malpractice suits were never so numerous, and they are brought frequently on the most trivial pretext, such, for instance, as the alleged failure to give consent to some particular line of treatment, or even simply as an offset to get out of paying a just bill. Even in legitimate experimental work on animals the physician is frequently annoyed and subjected to such interfering supervision as to make progress almost impossible. In view of these facts, it behooves the physician to familiarize himself more fully with the laws governing his obligations and liabilities to his patients and to the community, as well as the duties and obligations of the patients and the community to him. Every physician should study this little work carefully and thus become familiar with the laws which apply directly to him and to his work. As is well known, ignorance of the law is no excuse. If one will acquaint himself with the contents of this book, he may save himself much trouble, which a busy, unselfish life is but too frequently innocently or unknowingly brought on.

Practice and Problem in Abdominal Surgery. By A. Ernest Maylard, B.S., Surgeon to the Victoria Infirmary, Glasgow. Cloth. Price, $3.25 net. Pp. 388, with 39 illustrations. Philadelphia: P. Blakiston's Son & Co., 1913.

As the author states, this little work is not a treatise on the subject of abdominal surgery. It contains, however, an expression of the author's experience on a variety of subjects related to this great branch of surgery. He has had a wide experience during the entire period of what may be called modern abdominal surgery, and what he says is, therefore, the result of mature thought and judgment. He writes in an interesting and at times reminiscent manner, which is both entertaining and instructive.

Laboratory Methods. With Special Reference to the Needs of the General Practitioner. By B. G. R. Williams, M.D., assisted by E. G. C. Williams, M.D. With an Introduction by V. C. Vaughan, M.D., Professor of Hygiene and Physiologic Chemistry, University of Michigan. Second Edition. Cloth. Price, $2.50. Pp. 210, with 43 illustrations. St. Louis: C. V. Mosby Company, 1913.

That a second edition of this work has appeared so soon after the first is evidence of its popularity and worth to the general practitioner. The general worker must have laboratory facilities which permit of careful and exact work with the least expenditure of time and money. While many of the more complicated tests are denied to him, the busy practitioner must know the more common methods to be followed, the equipment necessary and the possible pitfalls into which he may grope in perfecting the tests at hand. To point out these various phases is the province of this work. Many changes and insertions have been made; among the additions are Bass and Watkins' rapid Widal method, which may be performed at the bedside in a few minutes; the sulphosalicylic acid test for urinary albumin, and the Hermann-Perutz serum test for syphilis. The last-named is a valuable addition as it enables the general man to study his suspected syphilitic cases without resort to the complicated Wassermann test, which he is not in a position to perform. This work should find a wide field of usefulness.

DIE BIOLOGISCHEN GRUNDLAGEN DER SEKUNDÄREN GESCHLECHTSCHARAKTERE. Von Dr. Julius Tandler, Professor der Anatomie, und Dr. Siegfried Grosz, Privatdozent für Dermatologie und Syphilidologie an der Wiener Universität. Paper. Price, 8 marks. Pp. 169, with 23 illustrations. Berlin: Julius Springer, 1913.

This interesting monograph attempts to explain the development of secondary sexual characteristics, anatomically speaking, by the harmonious cooperation of the several glands with internal secretions. The work itself is not a mere dissertation on the subject, but embodies the experimental labors, supplemented by clinical observation, of two authors well known in scientific medicine. Those interested in the new theories on the internal secretions will find much of value in the concise account of the authors on castration experimentally performed on the lower animals, as well as on castration as seen in man. Eunuchoidism, precocious sexual development, puberty, pregnancy, climacterium, hermaphrodism, the intermediate cells, all receive adequate consideration. The illustrations, though not numerous, are clear and really illustrative of the subject matter. The bibliography is up to date in every respect.

PATHFINDERS IN MEDICINE. By Victor Robinson. With a Letter from Ernest Haeckel and an Introduction by Abraham Jacobi. Cloth. Price, $2.50. Pp. 317, with illustrations. New York: Medical Review of Reviews, 1912.

This book is a collection of essays or sketches previously published in various periodicals. The "pathfinders" dealt with are: Galen, Aretaeus, Paracelsus, Servetus, Vesalius, Paré, Scheele, Cavendish, Hunter, Jenner, Laennec, Simpson, Semmelweis, Schleiden, Schwann and Darwin. The frontispiece is a representation in colors of the Semmelweis monument in Budapest, and there is an illustration of each of the persons whose life and work are sketched. As Abraham Jacobi says in his introduction, "the author's facts as related are absolutely correct," the style is animated, and to many the reading of these sketches should prove pleasant and profitable.

SURGERY OF THE LUNG. By C. Garrè, Professor of Surgery at the University of Bonn, and H. Quincke. Second Edition. Translated by David M. Barcroft, M.D. Cloth. Price, $4 net. Pp. 271, with 116 illustrations. New York: William Wood & Co., 1913.

This is a translation from the German, the original of which was reviewed recently in these columns. (Feb. 8, 1913, p. 471). The translation follows the original almost literally without additions or comments, and English readers have an excellent translation of the latest and perhaps best exposition of this newer field of surgery. All of the original plates and illustrations have been retained, as well as the bibliographies. The translation has a good index, which is wanting in the original.

THE REDUCTION OF DOMESTIC FLIES. By Edward Halford Ross, M.R.C.S., L.R.C.P. Cloth. Price, $1.50 net. Pp. 103, with illustrations. Philadelphia: J. B. Lippincott Company, 1913.

The purpose of this book is to describe the nature of the house-fly—its life, its danger to human beings, and the part it plays in causing sickness, and to show how it may be best reduced in numbers. Beyond reasonable doubt, flies are carriers of disease germs and possibly important factors in the dissemination of cholera infantum, typhoid fever and other maladies. The reduction, if extermination is not feasible, becomes of sanitary importance. Until the public understands that the house-fly is a dangerous pest which can be prevented, little or nothing will be done to institute prevention. In bringing about the desired reduction the base of operation is the destruction of breeding-places, chiefly of manure-heaps, garbage, open privies, etc. More than 500 million offspring may be produced by one female in one month. Destruction of the insect in the egg and larva stages, before the flying adult has developed, is the keynote of the author's suggestions.

Medicolegal

Accepting Prior Diagnosis of Another Physician and Treating a Fracture as a Dislocation—Delaying Use of Roentgen Ray and Anesthetics—Discharge of Physician Right after Correct Diagnosis—Principles of Law Governing Malpractice Cases—Standards

(McGraw vs. Kerr (Colo.), 128 Pac. R. 870)

The Court of Appeals of Colorado reverses a judgment for $800 given the plaintiff Kerr for alleged malpractice by the defendant McGraw. The court says that the evidence showed that the plaintiff, a boy of 5 years of age, fell from a horse and fractured his right arm. A physician was called, who, within an hour of the time of the accident, examined the arm, pronounced the injury a dislocation of the shoulder, bandaged the arm, bound it to the body, and, for lack of facilities at that place, advised that the plaintiff be taken to Denver for treatment. The next day the defendant was called, heard the history of the case, and was told by the boy's father of the diagnosis made by the other physician, and that he claimed to have reduced the dislocation, or, as the father expressed it, "pulled it back into place." The defendant examined the arm visually, and by feeling and manipulation found it swollen and painful; stated that it would be better to let the boy get over the shock before anything further was done, and that he would reduce the swelling and then could determine positively what the trouble was: recommended a Roentgen ray, but said he would not put the father to that expense until he deemed it necessary. The arm was rebandaged and complete rest and quiet directed. The defendant examined the arm daily, feeling of and manipulating it, and on several occasions applied electricity for treating the nerves or for the purpose of diagnosis. The swelling continued for some days—about one week according to testimony on behalf of the plaintiff—and longer according to the defendant. About two weeks after the accident the defendant discovered the fracture and immediatly ordered a Roentgen ray picture of the parts, which was taken the same day by a specialist in such work, and verified the defendant's diagnosis, showing that the ends of the fractured bone were not in exact apposition; only about three-fourths of the ends butting against each other. There was no lapping of the parts longitudinally. The plaintiff's father was then told the condition of the arm by both physicians, that they had detected crepitus, and both advised that the fracture be reduced under anesthetics, and that, if found necessary, a silver wire be inserted to hold the pieces in place. The fracture was of the surgical neck of the humerus about 1¼ inches from the rim or head of that bone. The defendant arranged to take the plaintiff next day to a hospital for an operation which it was understood he was to perform, but that night or early next morning he was discharged by the plaintiff's father and had no further connection with the case.

The plaintiff alleged that the defendant, being called to set a fractured arm, diagnosed the case as a dislocation of the shoulder, and treated it accordingly. The defendant alleged that he was called to treat a recognized case of dislocation, and to alleviate the suffering and condition arising therefrom.

The testimony of both the plaintiff and the defendant tended to support the latter view, and the defendant might have so understood his employment, as it was undisputed that he was notified on entering the case that the injury had been diagnosed by a physician as a dislocation, and the dislocation reduced; and it was admitted that for a time the defendant tentatively accepted such former diagnosis and treated the arm accordingly. The evidence failed to show that in the diagnosis defendant did not use the means and method ordinarily and usually used by other physicians. It was true, he did not at first make use of the Roentgen ray or of anesthetics. Both of these means were discussed by the defendant with the father of the plaintiff, and with his consent, or at least without objection, deferred for a time, and for apparently good reason. No evidence was offered to show that under the conditions it was usual or customary at that time and place, among physicians of the defendant's school, or immediately necessary to either use the Roentgen ray or resort to anesthetics in diagnosis, or that failure to do either constitute want of care or skill. By proceeding on a diagnosis not made by him, but accepted, the treatment by daily rotation or manipulation of the arm probably caused some degree of pain and suffering in excess of what the plaintiff would have endured if the fracture had been discovered sooner. But that treatment, in all probability, prevented a union of the parts and resulted in the nonunion as found by the defendant at the time he discovered the fracture. In view of the conditions, as stated, under which the defendant took charge of the case, there is reason for believing and holding that the failure of the defendant to use the Roentgen ray, or anesthetics, as a means of diagnosis, if error, was a mere mistake or error of judgment. The court is unable to see that such error, if error it was, was so gross as to be inconsistent with that degree of skill which it is the duty of a physician to possess.

The facts of this case differed from those of any reported case that has come to the court's attention. The court has read many in which the physician was held liable for improper diagnosis resulting in injury, but no case in which, although an incorrect diagnosis, or no diagnosis at all for a time was shown, it was followed by a correct diagnosis immediately after which the physician was discharged and his advice disregarded. This difference in facts marked a vital distinction in this case. It was clear that if the union of the parts which thereafter became permanent, and of which the plaintiff complained, did not exist at and prior to the time of the defendant's discharge, the defendant could not be held liable.

As the court views the case on the record, the only evidence of damages to sustain a verdict for any amount would be that which tended to show that the plaintiff suffered greater pain by reason of the manipulation of the arm while considering the injury a dislocation than he would have suffered had proper diagnosis been theretofore made. But the court is not satisfied that the jury intended to find, or might reasonably have found, a verdict in the amount herein returned for that element alone of the damage claimed. The verdict was so manifestly against the weight of the evidence as to appear to be the result of bias or prejudice, misconception of the evidence or the legal effect thereof, or of nondirection or misdirection as to the law.

In the absence of a special contract otherwise providing, a physician and surgeon employed to treat an injury impliedly contracts that he possesses that reasonable degree of learning and skill ordinarily possessed by other of his profession, and that he will use reasonable and ordinary care and diligence in the exercise of his skill and the application of his knowledge to accomplish the purpose for which he is employed, and that he will use his best judgment in the exercise of his skill in deciding on the nature of the injury and the best mode of treatment. He does not undertake to warrant a cure and is not responsible for want of success, unless that want results from failure to exercise ordinary care, or from his want of ordinary skill. If he possesses ordinary skill and exercises ordinary care in applying it, he is not responsible for mistake of judgment.

The skilfulness of a physician in diagnosis and treatment should be tested by the recognized rules of his own school, and must be determined by resort to the testimony and opinion of experts, not only as to the correct diagnosis, but also as to whether the defendant exercised ordinary care and skill in examining the case and applying the remedies, such opinion to be based on the facts in evidence. The fact that an injured limb is defective after treatment is not evidence of negligence on the part of the physician treating it.

A jury has no right to ignore testimony that has not been discredited and form independent conclusions on matters which require proof beyond their conjectures or opinions. Both from reason and authority it is clear that the result obtained from an operation, or treatment, in a case of medicine or surgery is ordinarily neither prima facie nor any evidence of negligence. A surgeon may be assiduous, painstaking and careful to the last degree, using all the recognized means at his command, both ordinary and extraordinary, and still fail. In such case it is manifest that failure is neither the result nor evidence of neglect.

A patient is bound to submit to such treatment as his surgeon prescribes, provided the treatment be such as a surgeon of ordinary skill would adopt or sanction. If he will not, his neglect is his own wrong or mistake for which he has no right to hold his surgeon responsible.

Negligence on the part of a physician consists in his doing something which he should not have done, or in omitting to do something which he should have done. By allowing the jury to consider any imperfect position of the fragments of the bone which had been broken, as evidence of negligence, the defendant was not tried for what he did or omitted to do, but by the criterion of results. If the jury could regard an imperfect position of the bone as evidence on the question of the defendant's exercise of care, then the doctrine of *res ipsa loquitur*, or the matter speaks for itself, applied; but the maxim *res ipsa loquitur* has no place nor application in a case like this, and the jury should have been so advised.

The defendant requested an instruction to the effect that. in considering whether the defendant in his diagnosis, care and treatment of the plaintiff's injured arm exercised ordinary care and skill, the jury could not set up a standard of its own, but must be guided in that regard solely by the testimony of physicians; and that, if they were unable to determine from the testimony of physicians what constituted ordinary care and skill under the circumstances of this case, then there was a failure of proof on the only standard for their guidance, and the evidence would be insufficient to warrant any verdict for the plaintiff. The authorities are practically uniform in holding, and counsel for the plaintiff admitted, that as to what is or is not proper practice in examination and treatment, or the usual practice and treatment, is a question for experts, and can be established only by their testimony, but counsel attempted to draw a distinction between the character of testimony necessary to establish a standard of proper treatment, and a standard of what constitutes ordinary care and skill. The court perceives no difference. If no standard was established by the testimony of physicians, then the jury had no standard. This does not militate against the right of the jury to decide between conflicting testimony of different physicians or experts on the question of a standard; it only goes to the extent that, if in doubt on any matter necessary to enable the jury to say that a standard has been fixed for its guidance by the testimony of such qualified witnesses, then it cannot from other and incompetent evidence, or without evidence, raise a standard. The court thinks that refusal to give this instruction, and the giving of an instruction by which the jury was permitted to find such standard from all of the testimony, both competent and incompetent as to that question, constituted error.

The fact that the defendant was discharged immediately after he had discovered the fracture and before he had set or attempted to set the arm was disclosed by the plaintiff's testimony in chief as well as by that of the defendant. Therefore it became necessary for the plaintiff to establish as an affirmative part of his case, by a preponderance of the evidence, that the condition of which he complained existed at the time of the discharge, and that permanent injury would not have been averted by compliance with the defendant's directions. The instruction given changed the burden of proof and placed it on the defendant, requiring him to establish by a preponderance of the evidence that such condition did not exist; that union had not taken place to such an extent as to make it impracticable or unreasonable for the plaintiff to comply with his advice that the fracture be reduced after that lapse of time. In that respect the giving of the instruction was error.

Silence and Failure to Act Not Evidence Against Physician

(Shelton vs. Hacclip (Ala.), 60 So. R. 471)

The Court of Appeals of Alabama reverses, on the second appeal in this case, a judgment rendered against the appellant (defendant) Shelton for alleged malpractice. The court says that the date of the alleged malpractice was August 10, 1903, when, as the defendant was passing the residence of the plaintiff's mother, he was called in by her in consequence of her having telephoned for a Dr. Murray, who had recently been attending on the plaintiff, and finding that he was not at his office, and that the defendant was not at that time the physician who had been treating the plaintiff, then a young child, for the ailment from which she had been suffering. The testimony for the plaintiff tended to show that the defendant was at the house again the next morning, and then saw the child's eye in the condition in which Dr. Murray observed it during the same day when he declared that it was out. The defendant's testimony was to the effect that he made only the one visit in August, when he prescribed for the eye, and that the next time he was called back there to see the child was in January, 1904. He did not remember for what ailment he prescribed for her on that visit, but there was no suggestion in the evidence that the calling in of the defendant on that occasion had any reference to the plaintiff's eye. The defendant having, on his cross-examination, testified that it was on that occasion that he first saw that the child's eye was out, he was required, over objections duly interposed in his behalf, to answer the questions: "You had made no inquiry about it before that?" "You made no inquiries at that time?" "You made no examination of the eye?"

The court cannot conceive that in asking these questions there could have been any other purpose than to make the defendant's answers to them, especially if they were answered in the negative, as they were, the basis of inferences or implications unfavorable to him. In other words, the effect of overruling the objections to the questions was to permit the facts that the defendant had made no inquiry about the child's eye after he prescribed for it in August, 1903, or when he was called in to treat her for some other ailment in January, 1904, and that he made no examination of the eye on that occasion to be put forward as evidences of implied admissions by him of some culpability on his part in the treatment of the eye for which he had prescribed.

The court is not of opinion that one's silence or failure to act can be made evidence against him unless the attending circumstances were such as to call for some expression or action by him in reference to the matter about which he then said or did nothing. It is a familiar rule that the fact that one was silent on a given occasion is not admissible in evidence against him unless the occasion was one calling for a statement or expression from him about the matter as to which his silence is sought to be given the effect of an implied admission. The reason underlying that rule also supports the conclusion that the fact of one's failure to do a certain thing should not be provable against him unless accompanied by evidence that there was some occasion for him to do that thing.

There was no evidence tending to show that, between the dates of the defendant's treatment of the child's eye on the occasion of his visit in August and his professional visit to her in the following January, anything had happened to which the defendant was a party or with which he was in any way connected which was calculated to elicit from him an inquiry as to the child's eye. Nor was there any evidence of anything being said or done on the occasion of his later visit to call for an inquiry by him about the child's eye or his examination of it. His failure, under these circumstances, to make such inquiries or examination could prove nothing for or against him bearing on the issue in this case, whether he saw the eye in August after it was out, as the plaintiff's evidence tended to prove, or first saw that it was out when he was called in to treat the child for some other ailment five months later. Evidence as to such failure could shed no light on the inquiry in this case as to whether the defendant was so in fault in the treatment he had prescribed for the child's eye as to render him liable in damages for the loss of it. His mere failure to make such inquiries or examination could have no legitimate tendency to prove that he was negligent or unskilful in the treatment of the eye or to indicate an implied admission by him of culpability in that regard. The conclusion follows that the court was in error in overruling the objections to the questions above set out, and this court is further of opinion that the error was a distinctly prejudicial one, as the evidence so improperly admitted might well be made the basis of a plausible appeal to the jury to give the defendant's subsequent silence and inaction a significance and an incriminating effect to which it was not entitled.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

Sixty-Third Annual Session, Sept. 22-26, 1913

Section on Surgery, September 23-25

The Section opened September 23 in the Bellevue Stratford. Dr. G. W. Guthrie, Wilkes-Barre, called the meeting to order at 2 p. m. The Chairman, Dr. John B. Lowman, Johnstown, delivered his address and then took the chair.

Treatment of Fractures

Dr. John B. Lowman, Johnstown: Each fracture is a study in itself and the simpler and more comfortably it can be dressed the better result will be obtained. The splint must fit the fracture, not the fracture the splint. In operation on fractures no instrument which has touched the hand nor the hand itself should go into the wound. In compound fracture my practice is to remove loose and disintegrated tissue, paint the wound with tincture of iodin and put on a 5 per cent. phenol dressing and a splint and not attempt operation until danger of infection is past. With an experience of over 150 operations I am an advocate of this method when there is interposition of muscle, absence of crepitus, when reduction is impossible and when the fracture is near a joint.

The Mimicry of Diseases of the Upper Abdomen by Omental Adhesions

Dr. G. P. Muller, Philadelphia: No substance as yet known will entirely prevent abdominal adhesions after operation. Probably simple incision of the abdominal wall causes slight adhesions. There is marked tendency of the omental edge to attach itself to raw surfaces of the peritoneum. Later larger surfaces become adherent. If this adhesion occurs at points well beyond the normal site, a drag on the stomach, colon or gall-bladder occurs and symptoms are produced which resemble ulcer, gall-stones or other disease of the upper abdomen. We should be cautious in diagnosing ulcer or gall-stones in a patient previously operated on unless we have eliminated the possibility of omental adhesion.

DISCUSSION

Dr. John B. Deaver, Philadelphia: I rely as much on a tender scar and rigidity surrounding the tender scar as anything else in making the diagnosis of adhesions. I frequently see patients return after gall-stone operations, not with the typical gall-stone colic, but with pain resembling it and with the same set of symptoms as before operation. I do not know any way of preventing these adhesions.

Dr. George P. Muller, Philadelphia: If a second operation has to be done I think that it is well to remove most of the omentum. Otherwise it is practically certain to adhere at the former point.

Puerperal Sepsis and the Present Methods of Treatment

Dr. E. E. Montgomery, Philadelphia: In the first place a careful differentiation from other forms of infection should be made, and the type, whether sapremic or septic, determined. In treatment, measures to conserve vitality, promote elimination and maintain nutrition should be employed. Medication should be given as much as possible hypodermically or by rectum. Elimination is most favored by continuous instillation of salt solution or water. The Fowler position promotes drainage from the vagina. Ice-bags to the abdomen lessen the pain and inflammation. Pus accumulations require, of course, surgical intervention. The curet should not be used.

DISCUSSION

Dr. Richard C. Norris, Philadelphia: My experience has taught me that the curet in miscarriages or following miscarriages is a prophylactic measure of treatment. We are apt to think that the uterus will take care of itself, but it is my routine practice with patients brought into my wards to take it for granted that there is something in the uterus that Nature has not taken care of, a nidus of infection. The intra-uterine douche after miscarriage has been productive only of good in my cases. After definite labor at term I never use the intra-uterine curet.

Fracture of the Surgical Neck of the Humerus

Dr. G. G. Ross, Philadelphia: Fractures of the surgical neck of the humerus often present great difficulties in treatment. Luxation of the head of the humerus is the most troublesome complication. It occurred in three out of eighty-four cases at the university and in five out of sixty cases at the German Hospital. Operation except in compound fractures is very rarely needed.

DISCUSSION

Dr. G. G. Davis, Philadelphia: The laity is becoming still more prone to malpractice suits, and in injuries about the shoulder I think it is almost impossible to make correct diagnosis by physical methods alone. Therefore, I think it absolutely essential that all injuries or fractures around the shoulder-joint should be roentgenographed. The conservative treatment of fractures in the neighborhood of the shoulder has proved to be better and more convenient than the operative means.

The Modern Diagnosis of Tuberculosis of the Kidney

Dr. B. A. Thomas, Philadelphia: Renal tuberculosis commonly masquerades under remote, unrecognized or misinterpreted urinary symptoms. Early diagnosis is necessary if it is desired to obtain the high percentage of cures possible by nephrectomy. The disease almost invariably arises from infection from the blood; rarely does it ascend from the bladder. In 80 per cent. of cases it is primary in one kidney only, but in twenty-four cases observed by me it had become bilateral at the time of operation. The use of tuberculin diagnostically is valueless. Cystoscopy and particularly chromoureteroscopy, with the employment of indigocarmin, has been the procedure of merit. Not a single patient nephrectomized after the use of indigocarmin has since died. Pyelography should seldom, if ever, be used in this disease.

Diagnostic Methods Applicable to Renal and Ureteral Lesions

Dr. G. M. Laws, Philadelphia: In the diagnosis of kidney lesions the history, physical examination, urinalysis and Roentgen rays are of importance in guiding the surgeon to a proper instrumental examination. Palpation may at once locate the affected organ. The Roentgen-ray examination of the kidneys and ureters has proved so valuable that it is used routinely. At times the roentgenogram will be negative in case of large calculus. That pyelography is an extremely valuable diagnostic method is undeniable. The experience of many clinics shows hundreds of cases that could not be diagnosed by any other method. Nearly every lesion of surgical importance causes some deviation from the normal outline of the pelvis or ureter. Indigocarmin and phenolsulphonephthalein are the most popular agents for use in functional tests. The practical objection to the latter is the necessity of using the ureteral catheter.

DISCUSSION ON RENAL DISEASE

Dr. J. E. Sweet, Philadelphia: Ascending infection of the kidney takes place, not through the lumen of the ureter, but solely through the lymphatic system.

Dr. John L. Laird, Philadelphia: If we depend on indigocarmin, we must rule out all obstruction in the ureter. We cannot do that without catheterization of the ureter. Besides, in early diagnosis, when diagnosis is most important, indigocarmin is often not delayed in its excretion. It has been stated and proved that one-third of the kidney substance must be involved before there is any delay in secretion of indigocarmin.

Dr. A. A. Uhle, Philadelphia: We cannot obtain a positive diagnosis of tuberculosis without positive guinea-pig inoculation. What we rely on is guinea-pig inoculation. After the diagnosis of a bad kidney we want to know, if the kidney is removed, whether or not the patient is going to live. I am much in favor of indigocarmin, but one must be very careful to choose the proper drug. There are two or three products on the market which may so mislead the operator that he might take out the kidney which is not diseased. Our results with tuberculin in kidney conditions have shown us that we secure relief, but we cannot depend on it for cure.

Ludwig's Angina, or Submaxillary Cellulitis with Extension to the Floor of the Mouth and Pharynx

Dr. T. Turner Thomas, Philadelphia: Ludwig's angina is a submaxillary cellulitis which extends to the larynx by way of the floor of the mouth and pharynx. Its greatest danger lies in the fact that the internal invasion is overlooked until it is too late or is not recognized at all. The recorded mortality is about 40 per cent. If the possibility of this complication in every case of submaxillary cellulitis were generally appreciated and the submaxillary focus were drained thoroughly as soon as the swelling under the tongue appeared, the mortality would be much reduced. If the incision was made before the internal invasion occurred, the results would be still better. The sublingual phlegmon should be the last signal for operation. Pus or dyspnea should never be waited for. Dyspnea develops too late and is too often absent in the stage when there is yet hope of saving the patient. While the condition which Ludwig described is a submaxillary cellulitis with secondary internal invasion, it should be borne in mind that the infection may start under the tongue or in the walls of the pharynx, when edema of the larynx will develop the more quickly and insidiously because the focus of infection is more concealed. Even in these cases the focus may sometimes be found and attacked successfully.

DISCUSSION

Dr. Ralph Butler, Philadelphia: We must forestall the danger rather than wait for fluctuation, dyspnea and other danger-signals. With early free drainage the mortality can probably be reduced, although some of the fulminating cases cannot be saved by any known treatment. The cases reported do not sufficiently emphasize the danger and rapidity of this affection. Death may occur within a day after the first symptoms are seen. The temperature often does not go above 101.

Our Present Conception of "Arthritis Deformans"

Dr. David Silver, Pittsburgh: According to our present conception of arthritis deformans, infection is the exciting cause in a very large proportion of the cases, whether in all remains to be proved. The source is usually focal and the infection is no doubt of various types, although streptococcal infection would appear to be the most common. Metabolic disturbances act as most important contributory causes, but that they alone can produce the arthritis cannot yet be definitely shown. To be emphasized is the fact that the problem is a complex one: there are numerous predisposing factors, while once the disease is established many causes become active in perpetuating it, and in some instances these secondary causes become so prominent as to appear of primary importance. Diagnosis is not a "one-man job."

DISCUSSION

Dr. G. G. Davis, Philadelphia: In a large number of cases we will fail to find the improvement expected on removal of the infectious element. In some cases the metabolic disturbance seems absolutely unassociated with the infectious element. Only by persistent work and study shall we solve the difficult problems connected with arthritis deformans.

Dr. George E. Pfahler, Philadelphia: I would call attention to the teeth as a source of infection in this condition often overlooked. Repeatedly these patients have come to me for roentgenoscopy of their joints and at my own initiative I have made studies of the teeth. Often with infection of the teeth the patients have no local symptoms.

Dr D. Silver: I agree as to the importance of pyorrhea, but this and the other common sources of infection may be secondary. In one case of infection of spine, hips and knees, the diseased tonsils were removed, with a large pocket of pus, but the patient did not get well. We must examine cases with regard to every point of infection.

Medical Ethics in Relation to Roentgenology

Dr. David R. Bowen, Philadelphia: The practicing physician should know enough about the Roentgen ray to tell when and when not it should be used. Patients should not be advised as to probable fee without due knowledge of fact and should not be encouraged to expect "pictures." Fee is for consultation and not for picture-making. The obligation is on roentgenologists and hospitals to furnish a high grade of service regardless of size of fee. The ownership of all roentgenograms and prints rests with the roentgenologist.

DISCUSSION

Dr. John H. Gibbon, Philadelphia: In stomach and intestinal work the Roentgen ray is invaluable. The matter must be in the hands of an experienced man; poor roentgenograms do more harm than to have none. If roentgenology is taught in medical schools I would approve the plan outlined by Dr. Bowen, which includes a warning of the attending dangers.

Dr. George E. Pfahler, Philadelphia: I believe we should teach medical students Roentgen-ray anatomy and Roentgen-ray pathology and give them the principles on which the subject is based both in diagnosis and treatment. I make no attempt to teach students how to do the work, but tell them that if they want to become roentgenologists they must take up the work, giving special attention to it. After fourteen years' hard study I realize how little I know of the matter.

Recognition and Treatment of Exophthalmic Goiter

Dr. Henry S. Plummer, Rochester, Minn.: The diagnosis of this disease is based on hyperplasia and change of form of the thyroid. The gland is enlarged, indurated in such a way as to be demonstrable in 60 per cent. of cases. A diffuse bruit is discernible in almost every case. Exophthalmic goiter must be distinguished from other thyrotoxic states. In exophthalmic goiter there are three toxic elements: one affecting the nervous system, the second the circulation and the third producing hypertrophy. The onset is insidious. The administration of iodin may cause cardiac symptoms in cases in which it had not previously been present. The simple form of goiter may be changed into the exophthalmic form. The constant features of the disease are mental irritation and depression. In persons over thirty-five years of age goiter, tremor, exophthalmia and tachycardia are not sufficient for the diagnosis of exophthalmic goiter. The toxic symptoms result from excessive and perverted thyroid secretion. The severity of the disease varies with the weight of the gland. The treatment consists in elimination of the cause, reduction of the hypertrophy and neutralization of the toxin. As we do not know the cause of the disease nothing can be done in that direction. Little can be expected, except from reduction of the functional activity of the gland by its partial destruction. Operation reduces the toxin produced in ratio to the amount of the gland removed. Alteration does not alter the perversion, nor does it alter changes in the organs which have already occurred.

DISCUSSION

Dr. Lawrence Litchfield, Pittsburgh: As in case of Banti's disease, which is probably due to a morbid influence of the spleen on other organs of the body, removal of the spleen will cure the disease. So it may be that the beneficial effect of thyroidectomy is due to the removal of the gland which is the cause of a perversion of secretion.

Dr. John A. Lichty, Pittsburgh: I should like to ask why hyperplasia of the gland is considered necessary for a diagnosis of thyrotoxicosis. I have observed cases of thyroid intoxication in which no hyperplasia of the gland could be determined.

Dr. Henry S. Plummer: Exophthalmic goiter never occurs without hyperplasia of the gland. In rare instances there are non-hyperplastic cases which resemble very closely exophthalmic goiter, but they are not that disease.

4. **Abderhalden's Test for Pregnancy.**—Thinking that possibly the ferment action of the blood might not be specific to placental albumin, one of the authors began to test the activity of the serum of pregnant and non-pregnant humans to ordinary peptones. Twenty c.c. of 2 per cent. sterilized aqueous solution of Witte peptone was mixed with 10 c.c. of blood-serum in a sterile flask. Of this mixture 10 c.c. was withdrawn immediately and titrated for amino-acids according to the formaldehyd method of Sorensen-Ronchesi. After incubation of the remaining portion for twenty-four hours the titration was again performed. The difference in titer represents in terms of tenth-normal KOH the increase of amino-acids as the result of digestion. Nine pregnant and three non-pregnant women were examined. The peptolytic activity of the blood varied in intensity, but the variation could not be brought into correlation with the gravid or non-gravid state of the patient, but depended on factors not ascertained. In four other cases, instead of peptone solution placenta was desiccated and powdered and a 1 to 200 suspension was made

and tests made in the same manner as already described. From these four cases no proteolytic activity could be demonstrated by an estimation of the amino-acids. If digestion of the placenta occurred it was either not carried to the amino-acid stage, or was not measurable by the method used. The few experiments as performed did not yield promising results so that this part of the work was abandoned.

When the use of ninhydrin and diffusion shells was advocated the authors took up the test. They used the dialysis tubes No. 579, 16 mm. in diameter. Seidenpeptone not being procurable, they used Witte peptone and normal horse-serum to test their tubes. The tests were performed with the strictest adherence to each new elaboration of the test as discovered by Abderhalden from time to time. Full regard to asepsis was paid and the facilities for work were satisfactory in every way. By the technic in which the placenta was not reboiled and retested just prior to the test, eleven patients were examined, of whom four were pregnant and seven non-pregnant. Each of the four pregnant women gave a positive reaction. Of the seven non-pregnant individuals only two failed to react. Of the five who reacted positively two were males with syphilis; one woman had been operated on one week earlier for tuberculous peritonitis, the uterus and appendages having been removed one year previously; one woman clinically non-pregnant but who had not menstruated for months, suffered from multiple ulcers of the rectum, probably syphilitic. Since rendering the placenta free of reacting substances before testing, they have tested seventeen individuals. Of five women who were not pregnant, one reacted positively. This patient had periods of amenorrhea from some cause not ascertainable. Of seven pregnant women from all periods, two reacted negatively in the sixth and fourteenth weeks, respectively, who subsequently developed positive signs of pregnancy. The women from the fourteenth week subsequently gave a second negative test. Of five puerperal women, two who had been delivered thirteen and twenty days prior to the test reacted negatively, the other three women were from the earlier puerperium and reacted positively. The dialysis tubes used in the adverse tests had previously and subsequently given positive reactions. Positive tests occurring when not expected can be explained on the basis of an error in technic, while a negative test is not so easily explained.

A review of the literature and an experience with the test, together with the use of other means of testing the digestive activity of the blood, leads the authors to question the specificity of the test of Abderhalden; though, since the need of such a reaction is great they urge that the test should be further tried, and its results reported accurately.

5. **Puerperal Infection.**—Watkins says that inasmuch as the disease is essentially a systemic infection, the important pathology is the general pathology of infection and immunity. The pathology in the pelvis in puerperal infection is of secondary importance when considered from a practical viewpoint. The bacteriologic examination of vaginal and uterine secretions is of relatively small value, as the results are often uncertain and misleading. Blood-cultures are the only means at present of accurate diagnosis of the variety of infection. As the disease is chiefly systemic, the treatment should be essentially general. The important part of the treatment of puerperal infection is the use of remedies to increase the body resistance, and the abandonment of measures that interfere with the development of immunizing substances. The outdoor treatment in Watkins' opinion is the most valuable remedy known as yet in the treatment of puerperal infection. The beneficial effects of that treatment in his cases have been very noticeable, especially as regards improvement in appetite, sleep, temperature and pulse. Two quarts is the minimum amount of fluid which is given to promote elimination. Stimulants are not used, as rest, not action, is desired. Anodynes or hypnotics are given in moderation to relieve pain and to procure a minimum amount of six hours' sleep. Watkins believes that fresh air and sun baths are good substitutes for tonics. An ice-bag is kept over the lower part of the abdomen during the acute period of the disease, and the head of the bed is elevated to promote drainage.

As the pathology in the pelvis is of secondary importance, the local treatment is of relatively little value. Watkins believes that much of the local treatment that physicians still use quite generally is productive of much harm and is of little benefit. Vaginal and intra-uterine douches and medicinal applications are harmful, meddlesome and useless procedures that are of historic interest only.

As to whether all products of conception be forcibly removed from the infected uterus, Watkins says, continues to be a debatable question. Never to explore or empty the uterus except for hemorrhage seems to Watkins to be consistent with the modern interpretation of infection and immunity. The infected uterus if left alone will soon spontaneously expel any retained products of conception. There is no evidence that the presence of such tissue increases the growth or virulence of the more dangerous bacteria. Emptying of the uterus removes most of the bacteria of decomposition, but they are not of much importance as regards morbidity or mortality. In the so-called saprophytic cases one can never exclude with certainty the presence of pathogenic bacteria. It is not an uncommon observation to see a normal temperature with retained decomposing tissue in the uterus. Curetting with the finger or instrument produces raw surfaces, disseminates the infection, may dislodge septic thrombi and thus produce embolic infections and pelvic inflammatory exudates. In case of hemorrhage, which means separation of the decidua or placenta, a gauze pack in the vagina or in the lower uterine segment will stop the bleeding and hasten spontaneous expulsion of the retained tissue. The gauze thus employed interferes with drainage and increases the absorption of toxins, but its use is the choice of the lesser of two evils. The infliction of traumatism on the infected uterus by forcibly emptying it is inconsistent with the modern treatment of infected wounds, and is an inheritance of a dangerous tradition which was based on a false pathology.

Watkins reports 100 cases dating back eight years when operative interference was discontinued, except in individual instances. Nearly all the patients were the severely infected ones who are usually referred to a hospital. Of the 100 patients, ninety-one recovered and nine died. Seven of the fatal cases had generalized peritonitis and were in an apparently hopeless condition on admission to the hospital. One died from large multilocular pelvic abscesses, which were incised and drained and terminated in generalized peritonitis and death. The other death was from a general hemolyzing streptococcus infection with numerous mycotic abscesses. Vaginal section was made twelve times for exploration and drainage. Seven of the patients thus treated were in the first twenty of the series, and only five of the patients out of the last eighty were so treated.

Forty-nine of the patients had pelvic exudates, which varied in size from slight indurations to masses that extended from the pelvic floor to the umbilicus. The relatively large number of these exudates is accounted for by the fact that most of the patients had been curetted one or more times and had become desperately ill before they were sent to the hospital. None of these exudates have required incision and drainage. These exudates had practically all disappeared at the time the patient left the hospital, after an average stay of between three and four weeks. The exudates have shown very little tendency to absorb while the fever existed. When the temperature became normal, i. e., when the exudate became sterile, absorption took place rapidly.

Six of the patients were subjected to abdominal section. All of these operations proved to be mistakes in diagnosis or surgical judgment. Three of them were of special interest. In two a large solid inflammatory exudate with extensive intestinal involvement was found. The abdomen was closed in both cases without disturbing the exudate. In both of the cases the exudate had entirely disappeared when the patient left the hospital about four weeks later. In one of these patients an abdominal section was made for suspected tubal pregnancy. The section revealed the presence of a streptococcus abscess involving the top of the left broad ligament, the ovary and the tube. Incision of the diseased tissue was easily made without much contamination of adjacent surfaces. Although this patient had practically no fever and was not very ill before operation, after the section she had a temperature of 103 F. to 105 F., had extensive suppuration and sloughing, and was for weeks dangerously sick. The indications are that this patient without operation would have made an easy, quick and complete recovery. Sixty of the patients were treated by supportive treatment only; in most of the other patients the treatment consisted chiefly in the use of remedies to increase the body resistance. In many of the patients the temperature curve has been peculiar in that the fever would be relatively high for periods of two or three days, with intervals of much lower average temperature for about the same time. This peculiar fever, Watkins believes, was probably due to remittent escape of bacteria into the blood-stream.

10. **Needs of Future in Hospital Administration.**—The chief of a medical or surgical service, Washburn says, can no longer give what the modern hospital requires by visiting his patients for an hour or two daily. The hospital should demand that each chief shall devote at least a half of each day to its service; that private practice shall be secondary. The ideal chief of service should have youth, yet his judgment must be mature; he must have vigor and enthusiasm. He must be just and generous in recognizing and promoting the efforts of his subordinates. He should be able to plan pieces of investigation for his staff and stimulate their accomplishment. He should see to it that the expensive "hospital days" are not wasted either by patients waiting the convenience of the surgeon for operation or by unnecessary stay in the hospital for sepsis. He would pay such men adequate salaries. His message to the larger hospitals is: Give more attention to medical and surgical efficiency and to that end get the right men for chiefs of service and pay them adequately to devote a large measure of time to the hospital.

He believes that too many small hospitals are started without adequate provision for their support. The result is a constant struggle and a probable attempt to make the unfortunate nurse in charge carry a greater burden than anyone should be asked to carry, both in hours of work and responsibility. He urges that medical men use their influence against the starting of a hospital until it has been clearly shown that it is necessary: that the location suggested best meets the need: that there is adequate support in evidence, and that its conduct is in the hands of those whose ideals are high and whose methods are practical.

14. **Classification of Nephritis.**—In studying the lesions of the kidney, Mallory states it is important to bear in mind that it is composed of a large number of small units. Every unit consists of an afferent vessel, and of a glomerulus composed of a knot of capillaries, and of a tubule. The blind invaginated end of the tubule is applied to the surface of the glomerulus. Its actual beginning is known as the capsular space. In addition to these four main structures of a unit there is an efferent vessel and a network of capillaries derived from it and surrounding the tubule. These vessels are of minor importance. A little connective tissue surrounds the vessels and tubule and extends in small amounts into the glomerulus.

Of these different structures in a unit the glomerulus, where blood-vessel and epithelium are in close association, seems the most susceptible to the action of injurious agents.

If any of the four essential parts of a renal unit is destroyed, the other three in time atrophy and cease to function. Each part is useless without the other three.

In order to understand the lesions of the kidney, Mallory says, it is necessary to separate it into its units and study the effect of injurious agents on each part of the unit.

The toxic lesions of the kidney are best classified on an anatomic basis, i. e. according to the part of the renal unit most affected. This classification gives four groups which form the type lesions; they are as follows: 1. Tubular nephritis. 2. Capsular glomerulonephritis. 3. Intracapillary glomerulonephritis. 4. Vascular nephritis (arteriosclerosis). Each one of these varieties may occur practically in pure form, but the first three may be, and often are, combined in varying proportions. Whether the first three can be recognized clinically as three distinct types, Mallory believes, is doubtful. While usually acute, they also occur in subacute and chronic form; vascular nephritis is always chronic.

15. **Urinary Acidity in Nephritis.**—Palmer has reached the conclusion that mild states of acidoses not infrequently occur in nephritis, and other unsuspected cases and that the therapeutic use of alkali (in such quantity as to reduce the urinary acidity to that of blood) is often desirable. He also believed that the deviation from the normal of the kidney function in acid excretion is important both in differential diagnosis and prognosis.

21. **Treatment of Genito-Urinary Tuberculosis.**—The authors advocate the judicial combination of surgery, proper hygiene, tuberculin and the careful consideration of the individual needs of each patient. They report on twenty-four cases of renal tuberculosis in which nephrectomy was performed. Only one patient died. The others are improving.

54 *Unusual Case of Appendicitis (Retrocecal) Associated with Rare Anatomic Anomalies. V. A. Lapenta, Indianapolis, Ind.

48. **Colliculitis.**—The treatment of the colliculus, Wolbarst says, consists almost entirely in the application of silver nitrate to the organ through the posterior urethroscope. He prefers a 10 per cent. solution, applied with a cotton carrier; a 20 per cent. solution is often recommended, and has known instances in which the pure silver stick has been employed. He believes there is no advantage to be obtained in the use of solutions of such great strengths, and that the reaction is sometimes too great to be of any service to the patient.

Similarly, with tincture of iodin; while it may be effective in weak solution, it is altogether too irritant in full strength, and the reaction which follows such an application is often so great that patients justly refuse a second treatment. Bleeding, urinary strangury, and tenesmus, and even complete retention of urine have followed these strong applications of silver and iodin. The galvanocautery may be used with benefit, and the Oudin high-frequency current likewise. The latter is particularly indicated in the presence of cystic and papillomatous growths, and also for the "fulguration" of dilated ducts and glands. Applications should be made at rather infrequent intervals, as allowance must be made for the passing off of the reaction which always follows. An interval of from four to seven days appears to Wolbarst the most satisfactory and beneficial.

54. **Unusual Case of Appendicitis.**—The patient consulted Lapenta on account of a "stone in the kidney." She related that this was the fourth attack that she had experienced in the last year. The face of the patient had the appearance of a prolonged toxemia, the facies peritonitica was lacking, abdomen was not at all distended, nor did the patient complain of abdominal distress. She did, however, complain of a pain in the lumbar region corresponding to the location of the right kidney. On palpation of the right iliac region pain was elicited. There was no rigidity of the rectus muscle nor was any muscular reaction caused by the pressure. The temperature curve as observed for three days was also against the diagnosis of renal colic, as it evidenced the presence of pus. The leukocyte count was 14,500; differential examination revealed 82 per cent. polymorphonuclear neutrophils with few eosinophils. Lapenta diagnosed retrocecal appendicitis.

At operation the cecum was found enveloped in a peritoneal membrane extending from above the iliocecal juncture to the end of the cecum, forming a well marked mesentery to the cecum, this membrane being strongly fixed to the posterior wall of the iliocecal fossa. The membrane was opened and gradually dissected from the underlying cecum on both sides of the gut and to the line where it resembled a mesenteric attachment. The folds of this false mesentery were opened and the appendix was then exposed. It was a very large appendix firmly adhered to the cecum. In this funnel-shaped envelope there was only a very small amount of pus. The appendix was dissected loose from the cecum and removed and the membrane was removed from its attachment at the posterior abdominal wall.

86 Relation between Carious Teeth and Malnutrition. C. D. Carter, Kingston.

85. **Cure in Hydrophobia.**—In a case of rabies cited by Haberlin, 10 c.c. of 1 per cent. aqueous solution of phenol were injected into the subcutaneous tissues of the abdominal wall by means of an Ehrlich-Hata syringe at 8:30 p. m. on the day of the attack, which occurred five weeks after the dog bite. At 9:00 p. m. 10 c.c. of a 2 per cent. solution were injected similarly and repeated in an hour. At 11:00 p. m. there was a very perceptible improvement in the patient's condition. Hourly doses of the 1 per cent. solution were now resumed and administered until 8:00 a. m. A total of eleven doses, therefore, of the 1 per cent. solution and two doses of the 2 per cent. solution were administered, or, in the aggregate, an equivalent of 1½ grams (22½ grains), of pure phenol. At 2:00 a. m., six hours after beginning treatment, the patient became somnolent, and when aroused was able to swallow readily. At this hour he was aroused for the first time by the insertion of the large caliber needle. He stated that he now was conscious of his surroundings for the first time since early evening, and when reminded of his previous actions and statements denied any realization of them. He was catheterized at 2:00 a. m., about 8 ounces of urine being recovered, which contained a trace of albumin, but was otherwise normal. He did not require catheterization again, and subsequent specimens were normal. On the fourth day the patient was out of doors, and on the sixth day resumed work, there being no further sequela than a few days' prostration, which reasonably may be ascribed to excess muscular activity. There were no evidences, locally or generally, of any deleterious effects of the exhibition of the phenol.

100. **Significance of Anemia as Operative Risk.**—Patients who have been anemic long enough to acquire the anemic habit, who have a normal or rather high blood-pressure, an erythrocyte count above 4,000,000, who are leading a physically active life without great discomfort and who are not noticeably emaciated, Byford says, make much better operative risks than the degree of anemia considered alone would indicate. On the contrary, anemic patients with a low blood-pressure, an erythrocyte count less than 4,000,000 and marked emaciation, who are unable to take a considerable amount of daily active physical exercise with comfort and without complaint, or who are bed-ridden and mentally hyperesthesic or depressed, often make much poorer risks than the degree of anemia alone would lead us to suspect. Anemic patients presenting one or more of these characteristics should be studied with reference to the hygienic conditions of their immediate past and the pathologic changes present. Starvation, hemorrhage, loss of rest, erroneous ideas or injurious habits with regard to work or indulgences or social duties, chronic or recent septic infection, incipient or chronic disease of any kind should be looked for. In other words, the surgeon should not operate, except in emergency cases, on an anemic patient until he has gone over the case history, the symptoms and the functions of the organs in a searching manner.

101. **Operations on Patients with Low Hemoglobin.**—Cullen finds that, as a rule, patients with a relatively low hemoglobin percentage stand pelvic or abdominal operations fairly well. Where carcinoma of the cervix or body of the uterus exists, however, the dangers are materially increased. In those cases in which the bleeding is limited entirely to the menstrual period it is well to defer operation until a few days before the next period in order to raise the percentage of hemoglobin to the maximum. Hyperplasia of the endometrium is a definite disease. The bleeding caused by this condition often leads to a low hemoglobin index, which can be temporarily checked by curetting. Sometimes after two or three curettings in the course of a year the excessive flow ceases. In other cases it is necessary to remove the body of the uterus. Cullen emphasizes strongly the necessity of becoming thoroughly familiar with the technic of transfusion. This procedure, as simplified by Bernheim, can readily be employed by any surgeon and should not require more than twenty minutes to half an hour. Transfusion will certainly in the near future become a routine procedure in cases in which operations are required on patients with a very low hemoglobin.

102. Abstracted in THE JOURNAL, May 31, p. 1737.

105. **Calcium Content of Blood During Pregnancy.**—The results of Morley's observations show that there is a lessened amount of calcium in the blood of pregnant and puerperal women and of women in labor. The actual calcium index varied somewhat from 1.2 to 0.06 crystals per square. Assuming that the arbitrary standard of Blair Bell of 1.5 to 1.2 is the normal calcium index of ordinary individuals of middle life, the results tabulated show that pregnancy, labor and the puerperium cause a withdrawal of calcium from the mother's blood. Just what the destination of the calcium is, whether taken up by the fetus during pregnancy, or by the uterus during labor, or by the breasts during lactation, must be left for later investigation. Morley suggests that some day the unsettled etiology of the toxemias of pregnancy may be explained by some disordered calcium economy on the part of the patient.

107. Abstracted in THE JOURNAL, May 31, p. 1737.

108 and 111. Abstracted in THE JOURNAL, May 31, p. 1734.

115. **Operation for Cure of Rectocele.**—Ward's operation consists in first completely separating the rectum from the posterior vaginal wall, as far up as the culdesac of Douglas, and then sliding the loosened rectal pouch high up along the vaginal wall by means of a suture. Thus the denuded rectum is carried up and placed so as to adhere strongly to the upper third of the posterior vagina which is above the former site of the rectocele. The perineorrhaphy described has been done in its essentials by Ward since May, 1908, with slight modifications from time to time. A buttonhole is made in each vaginal sulcus by passing a pair of closed scissors through the fascia, or the cicatricial tissue which has replaced it. This opens into the fossa in which lies the levator, the anterior edges of which are drawn out of the buttonholes with a forceps, and they are sutured together in the median line. The approximation of the anterior borders of the levator ani has been criticized as producing a weak support, owing to the fact that muscle applied to muscle will not make a firm union. To give the necessary fascial support to this muscular union and thus overcome this criticism, the writer carefully sutures the edges of the opposite fascial buttonholes together over the approximated levator fibers. The results of this procedure have been most satisfactory, as to the restoration of function, when used alone in cases without rectocele, and when combined with the rectocele operation.

116. Abstracted in THE JOURNAL, May 31, p. 1735.

117. **Treatment of Vesico-Vaginal Fistulae.**—The operation as here outlined by Parham has as its prominent feature the free exposure and mobilization of the bladder so as to pull it down sufficiently to make it accessible. The inaccessible fistula then becomes quite accessible. The essential features of the operation are: 1. Liberal dissection of the vaginal mucous membrane, so as to mobilize freely the bladder and bring the fistula within reach. 2. Beginning the dissection well forward, just behind the meatus urinarius, where the natural lines of cleavage make it possible to separate easily the vaginal membrane from the bladder wall. 3. The use of a lever in the bladder to push down the bladder so as to make the fistula accessible for suture.

1. See abstract No. 27 from the *Lancet*.

12. **Analogy Between Otosclerosis and Arthritis Deformans.**—O'Malley sums up his *conclusions* as follows: Chronic adhesive processes of the ear, or, as Kerrison calls it, chronic hyperplastic otitis media, is rheumatoid arthritis affecting the organ of hearing. Otosclerosis is osteo-arthritis of the stapediovestibular articulation and of the bony labyrinthine capsule. The morbid changes of chronic hyperplastic otitis media and rheumatoid arthritis are practically identical, and those found in typical otosclerosis are similar to those found in osteo-arthritis and in spondylitis deformans. As all the affected structures are developmentally, anatomically and physiologically alike, and when in these structures identical types of destructive and reparative changes occur, the natural inference to be drawn is that these processes are the result of a common pathogenesis. When in addition to the identity of morbid anatomy, we find a striking analogy between the two diseases in the points of age, sex, race, hereditary incidence, symmetry of lesion, trophic changes, courses, associated disease and conditions which are to influence onset and exacerbations, pathogeny and lines of treatment, the above seems to be the only conclusion to which an unbiased observer can come. In all the morbid changes there are two outstanding features—namely, atrophy and hypertrophy, running side by side or alternating, the atrophy being an active process as well as the hypertrophy. In the case of chronic hyperplastic otitis media and rheumatoid arthritis one finds the most marked activity of the disease in the soft or clothing tissues, which first undergo thickening, to be frequently followed by atrophy, the latter ultimately involving the supporting structures. In the case of otosclerosis and osteo-arthritis, the most marked activity of the pathologic changes is in the form of supporting tissues, the cartilage undergoing proliferation and ossification with the formation of osteophytic overgrowths. The essential pathogenic factor underlying an active atrophy and hypertrophy can be only one, namely, nutritional, although the conditions which may cause nutritive disturbances are manifold. As nutritional disturbances in tissue can be brought about by infective, vascular, nervous, traumatic and metabolic influences, either or all of which may be acting in any given case, it is therefore impossible to fit otosclerosis or osteo-arthritis into one air-tight pathogenic compartment. O'Malley is, however, of the opinion that the essential factor underlying the morbid changes is a chemical one, affecting the nutritive stability of developing and fully developed bone and cartilage, comparable to the rachitic phenomena which occur in developing osseous tissues, but how these chemical disturbances are *actually initiated* is at present not possible to explain.

14. **Gall-Stones.**—Steward holds that there is only one rational method of treating gall-stones, and that is to remove them by operation. This should be advised under the following *circumstances:* 1. *In cases exhibiting the characteristic* symptoms of gall-stone dyspepsia. 2. In view of the dangerous complications that may result from gall-stones, and especially that of cancer of the gall-bladder, and in view of the smallness of the risk attaching to an exploratory operation, this should be performed in all cases of intractable chronic dyspepsia of a type strongly suggesting the presence of gall-stones. 3. When there have been definite attacks of biliary colic, either with or without jaundice. 4. When the gall-bladder is or has been enlarged owing to impaction of a stone in the cystic duct. 5. In certain cases of obstructive jaundice, due to gall-stones impacted in the common duct. To decide when to operate in these cases is, in his opinion, the most difficult point in gall-stone surgery, and requires very careful judgment. It is, he says, clearly advisable in the absence of contra-indications to give the ducts a chance to get the stone through, and so finish the business. As to the length of this period of grace, that is determined by consideration of the following circumstances: If in the presence of obstructive jaundice the attacks of pain recur from time to time, that is evidence that the stone is not completely at a standstill, but is being gradually forced along the duct and may eventually pass safely into the duodenum. This may, of course, take some time, and there is a general opinion that three weeks should be allowed for the purpose. If, on the other hand, attacks of colic—indicating contractions of the duct—are not repeated, while obstructive jaundice remains complete, Steward takes this to be an indication that the stone is stationary, and would not wait more than about ten days if there are no

indications to operate sooner. The degree of inflammatory complication is, however, the real determining factor in this question, for it is this that most seriously affects the general condition of the patient, and so may make it imperative to operate. Thus if the liver is enlarged and tender, vomiting frequent, pyrexia marked, and the general condition of the patient progressively deteriorates while the pulse-rate rises, the risk of operative interference becomes daily greater, and there must therefore be no further delay. To sum up, Steward says: Wait a reasonable time before operating, but only if the patient's condition remains good and the temperature and pulse-rate are not rising.

25. **Tuberculosis of Cervical Lymph-Node.**—Pybus emphasizes that before removal of tuberculous lymph-nodes is advised, a general examination should be made to exclude other foci in the body. Although tuberculous cervical lymph-nodes are a localized infection from the tonsil, the tubercle bacilli present in the milk may equally well have infected the respiratory or digestive tract, and there may be extensive lesions in these parts in addition to those at the entrance to these tracts. Briefly detailed, Pybus' routine is as follows when a child presents itself with tuberculous lymph-nodes: If the tonsils are the infective focus, the child is first referred to the dentist to have any carious teeth removed. When the mouth is clean the tonsils are enucleated, and when the throat is healed general treatment or operation is carried out according as it is necessary. The site of an infective focus can be determined from the particular group of lymph-nodes enlarged. The pharynx and nasopharynx are the commonest sites from which the tubercle bacillus gains entrance. The tonsils are frequently tuberculous. A tuberculous tonsil may be enlarged; more commonly it is small and hidden, and very liable to be overlooked. Enucleation of the tonsil is essential if this is the infective focus. The supply of tubercle bacilli comes from tuberculous cow's milk. If the infective focus is removed the tuberculous lymph-node may undergo a natural cure. If caseation has progressed far in a lymph-node complete resolution is almost impossible, and if the disease fails to improve on treatment, removal of the node should be carried out. A rapid enlargement or softening of a node means that a subcutaneous abscess has formed, and that scraping will not cure it. The node causing the abscess lies under the deep fascia and may be quite small. Prevention is better than cure. Operations are difficult and should only be undertaken by a skilled surgeon, while recurrences, even after extensive dissections, are not unknown. Tuberculous cervical lymph-nodes, Pybus states, are a local disease, but are often associated with tuberculosis elsewhere in the body. The results of treatment may therefore be disappointing, and this emphasizes the necessity for general sanatorium treatment.

27. **Dynamic Side of Biochemistry.**—Hopkins draws attention to certain of the various steps by which we have arrived at a knowledge of the synthetic powers of the animal body. Commencing with the original discovery of Andrew Ure that an increased excretion of hippuric acid followed on the exhibition of benzoic acid he detailed the experiments of Bunge and Schmiedeberg, and alluded to the question of how far the body could extend its supply of glycin when stimulated by increasing doses of benzoic acid. He next dealt with the researches of Baumann and the syntheses where the sulphur group plays a part, in which substances are so treated in the body as to reappear in conjugation with protein derivatives; with the syntheses in which the substance supplied by the body is derived, not from protein but from carbohydrate; with the methylation undergone by certain compounds. Recent progress points in the clearest way to the fact that the molecules with which a most important and significant part of the chemical dynamics of living tissues is concerned, are of a comparatively simple character. The synthetic reactions which have been described surely prepare us for this view; but it may be felt that, however important, they represent abnormal events, while the study of them has been largely confined to determining the end-products of change. With regard to normal metabolism and intermediary reactions, Hopkins says we know first of all that the raw material of metabolism is so prepared as to secure that it shall be in the form of substances of small molecular weight; that the chief significance of digestion, indeed, lies in the fact that it protects the body from complexes foreign to itself. Abderhalden has ably summarized the evidence for this, and has shown us also that, so far as the known constituents of our dietaries are concerned, the body is able to maintain itself when these are supplied to it wholly broken down into simple *bausteine*, any one of which could be artificially synthesized with the aid of our present knowledge. Dealing especially with the proteins, we have good reason to believe that the individual constituent amino-acids, and not elaborate complexes of these, leave the digestive tract, while Folin, Van Slyke and Abel have recently supplied us with suggestive evidence for the fact that the individual amino-acids reach the tissues as such and there undergo change. But still more important, Hopkins believes, is the fact that recent work gives clear promise that we shall ultimately be able to follow, on definite chemical lines, the fate in metabolism of each amino-acid individually; to trace each phase in the series of reactions which are concerned in the gradual breakdown and oxidation of its molecule. Our knowledge of the fate of amino-acids is arrived at by the combination of many ingenious methods of study. It is easy in the animal, as in the laboratory, to determine the end-products of change; but, when the end result is reached in stages, it is by no means easy to determine what are the stages, since the intermediate products may elude us. And yet the whole significance of the processes concerned is to be sought in the succession of these stages. In animal experiments directed to the end under consideration, investigators have relied first of all on the fact that the body, though the seat of myriad reactions and capable perhaps of learning, to a limited extent and under stress of circumstances, new chemical accomplishments, is in general able to deal only with what is customary to it. This circumstance has yielded two methods of determining the nature of intermediate products in metabolism. Considerations of molecular structure will, for instance, suggest several possible lines along which a given physiologic substance may be expected to undergo change. These possibilities may be tested by administering various derivatives of the substance in question. Only those which prove on experiment to be fully metabolized, or to yield derivatives in the body identical with those yielded by the parent substance, can be the normal intermediate products of its metabolism. All others may be rejected as not physiologic. Metabolic tissue reactions are catalyzed by enzymes, and, knowing the general properties of these, we have every right to conclude that all reactions may be so catalyzed in the synthetic as well as in the opposite sense. If we are astonished at the vast array of specific catalysts which must be present in the tissues, there are other facts which increase the complexity of things. Evidence continues to accumulate from the biologic side to show that as a matter of fact, the living cell can acquire *de novo* as the result of special stimulation new catalytic agents previously foreign to its organization. It is certain, from very numerous studies made on the lower organisms, and especially on bacteria, that the cell may acquire new chemical powers when made to depend on an unaccustomed nutritive medium. Twort has shown that certain bacteria of the colityphosus group can be trained to split sugars and alcohols which originally they could not split at all. A strain of *B. typhosus* which after being grown on a medium containing dulcite had acquired the power of splitting this substance, retained it permanently,

even after passage through the body of the guinea-pig and cultivation on a dulcite-free medium. Similar observations have been made by Massini and Burri; the latter showed by ingenious experiments that all have the same potency for acquiring it. Yet no one will deny that the appearance of a new enzyme is involved in this adjustment of the cell to a new nutritive medium. We have not, Hopkins says, so much evidence for similar phenomena in the case of the higher animals. The milk-sugar splitting ferment may be absent from the gut epithelium before birth, and in some animals may disappear again after the period of suckling, but here we probably have to do with some simple alternation of latency and activization. But among the protective ferments studied by Abderhalden are, perhaps, cases in which specific individuals appear *de novo* as the result of injecting foreign proteins, etc., into the circulation. Hopkins admits that he has allowed himself to go beyond ascertained facts in dealing with this last point. But once having granted that specific number of reactions, there seems to be no logical reason for supposing that a different class of mechanism can be concerned with any particular reaction.

34. **Ovarian Cyst Exposed Per Vaginam.**—Kemp describes the case of a Tamil Mahomedan woman, aged 30, who was delivered of a full-term fetus on the morning of her admission to a hospital, but actually before admission. The midwife relates that just before the child was born, the membranes being already ruptured, there appeared a membranous, as it seemed, presentation beside the head. The "bag" suddenly protruded out of the vagina and was found to have a pedicle about an inch thick, the "bag" being of the size of a small cocoanut. The child immediately after was born and the placenta came away naturally, but the "bag" remained attached by its pedicle to the inner parts. At the hospital it was seen that a cystic tumor was present in the appearance of a "bag." The pedicle, 2½ inches in length, could be felt to extend to as far as what seemed the anterior wall of the vagina or cervix (an erroneous conclusion), and a very patulous state of the cervix, as it was afterward ascertained to be, gave the impression that a further cystic condition was internally extending beyond the pedicle. The cystic tumor was supported on towels and wrapped around in aseptic gauze dressings to be later more carefully dealt with. Two or three days later, the patient being in the meantime in no pain or distress, and with no temperature or other morbid sign or symptom, the tumor was very closely examined under an anesthetic. It was then recognized as a cyst that had the fimbriated extremity of the fallopian tube of the left side attached to it, showing up on its higher aspect of the cyst close to the attachment of its "pedicle," the latter being only the stretched broad ligament (left side) containing the rest of the fallopian tube.

52 *New Method for Treatment of Bacterial Infections (Modification of Vaccine Treatment). N. F. Surveyor.

41. **Unusual Cases of Hyatid Disease.**—O'Hara cites cases of hydatid at the back of the eyeball, hydatid on the brain, hydatid on the left lung implicating the pericardium, spontaneous fracture of the humerus caused by hydatid cyst in the shaft of that bone, hydatid in the jawbone simulating *actinomycosis,* hydatid in the apex of the right pleura simulating aneurysm of innominate artery, hydatid in the posterior surface of the liver pressing on the head of the pancreas, simulating disease of that gland and hydatid at the base of the lung causing laryngitis.

44. **Radium in Malignant Disease.**—The practical conclusions which Knox deduces from his consideration of the value of radium in the treatment of malignant diseases are: 1. In all cases of early cancer the operative method is undoubtedly the best; it is quicker, safer, and offers the best prospect of a cure. 2. Radium is a useful adjunct to the treatment of all cases, first as a prophylactic after operation, and, failing operation, the next best method we possess. It must, however, be stated that Roentgen rays are in selected cases quite as useful as radium. 3. In cases which refuse operation or are for other reasons not suitable for operation, radium is a useful remedy. 4. In inoperable cases, radium may help to render the case operable; and, failing that, is undoubtedly useful as a palliative measure.

47. **Ergot and Its Preparations.**—The authors propose a revision of that section of the British Pharmacopeia relating to ergot, and indicate the following changes: 1. The present Extractum Ergotae to be abandoned and, if necessary, a soft total extract made with 60 per cent. alcohol acidified with citric acid, substituted for it. 2. The fluid extract of the United States Pharmacopei.., made with 49 per cent. alcohol, containing 2 per cent. of acetic acid, should take the place of Extractum Ergotae Liq. 3. The Injectio Ergotae to be abandoned and suitable salts of ergotoxin, either alone or combined with the active amines, Ergamine and Tyramine, to be employed in place of it. 4. The adoption of a liquid extract such as that described would render the tincture unnecessary, but such if retained should be made by percolation with 60 per cent. alcohol without ammonia.

49. **Repair of Fractures.**—Groves holds that screws which merely bite into the side of the bone will rapidly loosen by a process of bone absorption, if they are subjected to much tension. They are therefore unsuited for the operative treatment of fractures. Absolute fixation of fractured ends, he believes, is conducive to good repair. The only way in which fractures can be firmly united by plates is by the use of pins, screws and nuts which perforate the whole thickness of the shaft. Great mobility of the ends of a fractured bone is likely to produce a false joint, especially in the case of a single bone like the femur. Marked mobility of the ends of a fractured bone cause a great excess of callus. Metallic *magnesium* is absorbed in a bone and causes great callus excess. Indirect methods of fracture fixation give the most ideal results, and this is the only method possible when dealing with compound and comminuted cases. Groves states that the periosteum has no power of forming callus or new bone, although it is of great value in serving as the chief blood-supply to the callus and in limiting its extent. Active callus and bone formation always occur from the broken surface of the bone and every small fragment acts as a center from which new bone growth may take place.

52. **Treatment of Bacterial Infections.**—The method as adopted by Surveyor is to take a measured amount of pus and dilute it with varying amounts of normal saline, so as to get definite dilutions of the toxins present in the pus. This dilution is used for injections. The method was found to be particularly applicable to certain cases that showed a large number of various organisms in smears of pus obtained with all bacteriologic precautions, none of which, however, could be made to grow in the test-tube. The material in such cases was mostly foul-smelling, although taken from unopened abscesses. Various dilutions of the pus (from 1 in 10 to 1 in 600) have been tried, and it was found that a dilution of 1 in 50 is suitable for most cases of staphylococcic infection and

1 in 100 for streptococcic infection. Counting the number of bacteria injected for the purpose of standardization, as is done in the case of ordinary vaccines, is not applicable here, as the disintegrated corpuscles and other débris interfere with the counting process; nor is this necessary. The strength of the "autoxin" can be fairly definitely adjusted by the amount of dilution used.

53* Operative Treatment of Hydrocele. Vautrin.
54 Causes and Treatment of Cholelithiasis. L. Delrez.
55 Salpingitis in Virgins. Fructus.

53. Hydrocele of the Vaginal Tunic of the Testicle.—Vautrin has applied in eighty-eight cases since 1890 his method of eversion of the tunica vaginalis, and states that there has been no recurrence in any instance except in one of his first cases. For ordinary hydrocele, simple eversion is enough, drawing out the testicle while allowing the vaginal tunic to retract and fold back on the cord; it is then fastened to the infundibuliform sheath of the cord with three stitches of silk thread, one at the back, at the posterior commissure of the opening in the vaginal tunic, the others on each side. By this means the vaginal tunic exposes its other side to the testicle, and there is hence no possibility of recurrence of the hydrocele from the same mechanism as before. Vautrin's experience, however, has demonstrated that it is best to excise the entire fibrous sac and the vaginal tunic with it when the tissues have become thick and hard, forming a hard shell. In less advanced stages he partially resects the vaginal tunic before doing the eversion, and commends these three types of the technic as adapted for all the various conditions that may be encountered.

September, II, No. 9, pp. 97-144

56 *Spontaneous Torsion of Sound Fallopian Tube. M. Auvray.
57 Extra-Membranous Pregnancy; Two Cases. Brouha.

56. Torsion of the Sound Ovary or Tube.—Auvray reports a new case of spontaneous torsion of the sound fallopian tube. In the six cases which he has compiled the torsion involved both tube and ovary in two cases, once the tube alone, once the ovary alone, and in Cassidy's case the ovary, the tube and the broad ligament were all included in the torsion. In four of the total six cases the mistaken diagnosis of appendicitis had been made. The effect of the torsion is generally such that the adnexa on that side have to be removed. In the case here reported the torsion had evidently occurred very gradually; the patient had complained for two years of occasional pains in the right iliac fossa. The pains gradually increased in intensity until, possibly under the influence of menstrual congestion, the tube became twisted twice around with all the symptoms of acute strangulation.

62 Improvement under Abbott's Method of Treating Curvature of the Spine. (Scolioses graves traitées par la méthode d'Abbott.) Lance.
63 Cure under Radiotherapy of Pigmented Nevi. (Traitement des taches de vin.) A. Weil.
64 *Operative Treatment in Infantile Paralysis. (Les interventions ostéo-articulaires dans la paralysie infantile.) Barbarin.
65 *Albumin-Milk: Dangers of Lack of Sugar in Infant Feeding. (Essais sur le lait albumineux. Les dangers de la privation du sucre chez le nourisson.) P. Nobécourt and G. Schreiber.
66 The So-Called Mongolian Blue Spot. (La tache mongolique dans l'état de São-Paulo, Bresil.) C. Ferreira.

58. Sugar in Infant Feeding.—Variot adds another to the cases previously published by him in which uncontrollable vomiting stopped after the infant was fed on highly sweetened condensed milk. This infant was nine months old and weighed only half the normal. The vomiting had been constant for a long time, but it stopped at once when the much diluted, sweetened condensed milk was given. The mother changed afterwards to a condensed milk that was not sweetened, and the vomiting reappeared but stopped again on resumption of the highly sweetened milk. In three months the child was thriving and was of approximately normal size for its age. When first seen the stomach was found very much dilated, both stomach and colon greatly distended with air; infants suffering from lack of nourishment generally swallow air in large amounts.

59. Spasmophilia with Acute Encephalitis. — The case reported presents a new argument in favor of the brain and nerves, instead of glandular secretion, being responsible for spasmophilia in a certain proportion of cases.

61. Splenic Anemia.—The anemia seemed to be of a severe, pernicious type in the two cases reported, and was accompanied by great enlargement of the spleen. The patients were children of 10 and 3 and both recovered. The first had a tendency to hemophilia and was given calcium chlorid, beef marrow, arsenic and iron, while the spleen was exposed to the direct sunshine twice a day for fifteen minutes. In the second case there were traces of rachitis and of an epidemic suppurative affection of the gums. This child also recovered under iron, arsenic, iodid and fresh air. The cases teach that the outcome depends more on the cause than on the degree of the anemia.

64. Operative Treatment of Infantile Paralysis.—Barbarin has obtained excellent results with transfixion of the bones to induce arthrodesis in treatment of crippled joints from epidemic poliomyelitis—Veau has always found that exposing the surfaces of the articulating bones was sufficient to ensure their growing together, so that transfixion is superfluous, he insists, to induce arthrodesis in these cases.

65. Sugar in Infant Feeding.—Nobécourt and Schreiber gave the Finkelstein albumin-milk to twenty-one infants and state that fairly satisfactory results were obtained in only two cases; no benefit in five, while fourteen of the children showed a notable aggravation of their condition on this food. They insist that the lack of sugar, which is one of the special features of this albumin-milk, is directly injurious and that there is no evidence to prove that sugar is harmful in infant feeding. They add that Finkelstein recognized this later, and now sweetens the albumin-milk after from six to twenty-four hours, commencing with 3 per cent. They add that there does not seem much logic in suppressing the lactose of the milk to replace it with cane sugar or malt sugar in this way.

September 10, No. 74, pp. 741-748

71 Contusion of the Abdomen. E. Kirmisson.
72 Behavior of Other Lung with Therapeutic Pneumothorax. (Comment se comporte le poumon "opposé" dans le traitement de la tuberculose pulmonaire par le pneumothorax artificiel.) R. Burnand.

70. Treatment of Furunculosis.—Mauté warns against more than a minute puncture to permit aspiration of the contents of a furuncle. He also warns against large dressings as any contact or rubbing is liable to lead to new inoculations of the staphylococci on the skin even at some distance from the furuncle. He applies the smallest dressing possible, held in place with plaster strips. The skin should be disinfected with camphorated alcohol or ether or tincture of iodin, but not much can be hoped from this as the sterilization is only superficial and does not reach the germs deep in the hair follicles, etc. General tonic measures are indispensable to augment the resisting powers, but the main reliance is on vaccine therapy, and he thinks that the dosage of the vaccine is the key to successful treatment of furunculosis. Incorrect dosage is liable to sensitize, rather than to cure, the patient. Other drugs are seldom needed, unless possibly in inveterate cases of folliculitis dilute sulphuric acid as recommended by J. Reynolds, from 60 to 120 drops a day in a large glass of water at meals. The necessity for curing furuncles and not letting crops develop has been impressed on Mauté anew recently by a case of abscess in the kidney, three cases of abscess in the prostate and two of perinephritic abscess, all following after a single furuncle.

Revue Pratique d'Obstêtrique et de Gynécologie, Paris

77 *Turpentine Tampon for Puerperal Endometritis. (Du tamponnement à l'essence de térébenthine pure dans l'endométrite puerpérale.) P. Delmas.

74. **Viability of the Prematurely Born.**—Tissier has recently reported that an infant born at the sixth month of pregnancy lived for two months; it weighed 900 gm. at birth. Budin has reported a case in which an infant was born nearer the fifth than the sixth month of the pregnancy, weighed 650 gm., and lived for a month. Leclercq reported last year the survival for twenty-one hours after birth of a prematurely born infant that weighed 670 gm. and measured 25 cm., or less than 10 inches, and the anatomic findings corroborated the history of the case as a birth at four and a half months after conception. Dervieux cites these cases to show the necessity for revision of the French laws in regard to inheritance of property and paternity; they specify 180 days as the limit for viability and possible paternity.

77. **Turpentine in Local Treatment of Puerperal Fever.**—Delmas calls attention to the excellent results he has obtained in a number of cases of puerperal endometritis with turpentine. The long strip of gauze *imbibée à refus*, as he says, with the oil of turpentine is packed in the uterus, the outer end of the strip left in the vagina, the walls of the latter protected with an isolating sheet of cotton, and the vulva with petrolatum. He leaves the strip of gauze or wick in the uterus for twenty-four hours. The almost elective action of turpentine on the streptococcus is supplemented by the intense afflux of leukocytes which it induces, and by the general antiseptic action of the turpentine absorbed by the gaping vessels in the uterus. Its absorption is rendered evident by the odor of the turpentine in the urine for several days.

84 Mental Disturbances during Pregnancy. (Psychosen während der Schwangerschaft.) C. A. Passow.
85 Pathologic Findings, etc., in Fossil Animals. E. Hennig.

82. **Neuralgia in the Trunk.**—Zuelzer warns that acute and chronic rheumatism of the vertebrae, tuberculous processes in the bronchial lymph-nodes and disturbances in the spine of the same nature as those in the foot from flat-foot—these three affections may induce sharp pains—actual spinalgia, simulating various other troubles and liable to be misinterpreted and mistreated. The pain and hyperesthesia with these affections are always bilateral. The patient may not be aware of this bilateral character—usually not—but it can be determined by delimiting the area with the needle and studying the character of the pain which is always typical of true neuralgia. The zones of hyperesthesia are abnormally sensitive to contact, to pressure and to temperature. The "pressure points" are also excessively tender. With insufficiency of the spine there may be pains lower than with tuberculous processes in the bronchial lymph-nodes, and the patient may locate the pains in the stomach, intestines or kidneys. Investigation with the needle will show, however, that although the patient complains only of one side, there is in reality a sharply defined bilateral intercostal neuralgia. In two cases of the trouble in the spine similar to flat-foot, the pains predominated on the right side and both patients had been operated on for supposed gall-stones but none was found. One had been operated on twice and a third operation was contemplated as the persisting pains convinced the surgeon that he must have overlooked the gall-stone. The patient, a woman of 42, had had 120 attacks but no jaundice or fever. To avoid bringing on the attacks she had eaten less and less, and was bed-ridden and much debilitated. Zuelzer could find nothing to indicate gall-stones; the liver was not enlarged, while the painful area was that innervated by the seventh to tenth thoracic nerves; corresponding to this the spine at the ninth and tenth thoracic vertebrae was extremely sensitive to pressure, and there was a pronounced tendency to curvature. She was fitted with an orthopedic corset and almost at once she was freed from all disturbances. Another patient was a man who had been operated on for supposed duodenal ulcer but no ulcer was found, and the typical pains of the vertebral insufficiency persisted as before.

In three cases of acute rheumatism of thoracic vertebrae the pains and objective findings were the same as with vertebral insufficiency, except that the anterior branch of the intercostal nerve in all three cases did not seem to participate in the hyperesthesia. Under treatment for rheumatism, the neuralgia disappeared. These three cases confirm the assumption that the peculiar circumscribed neuralgia in such cases is not an imaginary hysteric hyperesthesia but true intercostal neuralgia. The vertebrae in the neck are more liable to subacute or chronic rheumatism, and here also the neuralgia, felt by the patient on one side only but shown by the needle tests to be bilateral, gives the clue to the diagnosis. The location of these root neuralgias corresponds to the eruption of herpes, and neuralgia can be positively excluded if the needle fails to reveal a corresponding area of hyperesthesia in the skin.

83. **Serotherapy in Pregnancy Dermatitis.**—Wolff reports a case of severe pruritus and dermatosis for which the pregnancy was evidently responsible and which all subsided at once after intragluteal injection of 10 c.c. of inactivated serum from a healthy woman delivered two weeks before.

September 13, No. 37, pp. 1155-1184

89 *Distilled Water in Medical Practice. A. Barladean.

86. **Acute Dilatation of the Stomach.**—Stierlin's patient was a boy of 10 with acute dilatation of the stomach following overloading the stomach with baked apples. He found that the child had spontaneously assumed the knee-elbow position to obtain relief. A characteristic feature of the vomiting with acute dilatation is that small amounts are repeatedly vomited, no single large amounts. The intolerable thirst compels the patient to keep drinking copiously, which keeps up the morbid condition. The pulse is rapid but the temperature is normal or below. The stomach in this case failed to recuperate and finally a gastro-enterostomy put an end at once to all disturbances. The trouble was explained in this case by the

discovery of a few adhesions and two cheesy lymph nodes in the mesentery of the jejunum, predisposing to the dilatation on any dietetic indiscretion.

89. **Distilled Water.**—Barladean comments on Wechselmann's discovery that certain toxic effects of salvarsan could be avoided by using freshly distilled water. Ordinary distilled water, he found, contained quantities of bacteria and, although killed by boiling the water, the dead bodies of the bacteria caused disturbance in intravenous injection. Barladean cites the investigations of a number of other workers in this line: Müller examined sixteen specimens of distilled water from the stock of different drug stores and found only two that contained less than 100,000 germs, two containing over 700,000, and one 6,050,000 per c.c. Barladean quotes others to show that not only bacteria but alkali from the glass and metals from the retort, etc., may add to the contamination of distilled water. The influence of even minute amounts of these may be harmful. We know that a thousand millionth part of copper is fatal to a certain fresh water plant, the *Spirogyra*, and another plant, the *Vaucheria*, is even more sensitive to copper ions. He remarks that distilled water is usually kept in large bottles and these bottles can never be thoroughly cleansed. The German Pharmacopeia's requirement for distilled water is that 100 c.c. on evaporation should not leave more than 0.001 gm. residue. This amounts to 0.01 gm. in a liter, and the distilled water is thus merely a dilute solution (1:100,000) of unknown substances. This contamination, Barladean insists, may modify the effect of drugs, even those taken by the mouth. The chemical tests should be supplemented, he declares, by biologic tests with the Spirogyra (to test for metal ions), by bacteriologic tests, as for potable waters, and by testing the electric conductibility of the distilled water.

90. **Weak Heart.**—Hering's article was one of the addresses at the recent International Medical Congress. He reviews the data on which he bases the conclusion that weakness of the heart means not only less contracting power but less power to generate impulses or transmit them. He states that the subjective symptoms of weak heart have been too much neglected, and that sensations originating in the heart can often be rendered objective by determination of the ultra-sensitiveness of certain areas of the skin. The jugular pulse is a valuable sign of functional disturbance of the heart but it does not testify to tricuspid insufficiency as formerly believed. The dilatation of the heart which results from weakness, he says, must be called an incompensatory dilatation, in contrast to the dilatation which is due to efforts at compensation. If we accept for the tonus of the myocardium the ability to keep the heart of a certain length, then this tonus is subnormal in dilatation of both types. Consequently, hypotonicity of the myocardium cannot be accepted as always the direct result of weakness of the heart muscle.

In examining the heart it must not be forgotten that there is never a single cause; every process has a plurality of contributing factors. The symptoms most important for a rapid and certain diagnosis in general practice are perpetual irregularity of the heart action; dropping out of the auricle and ventricle systole; dropping out of the ventricle systole; alternating heart action, and dissociation. He calls these the economic symptoms of weakness of the heart. The incompensatory dilatation of the heart does not belong in this group of economic symptoms as its detection requires certain co-symptoms. Even in studying an economic symptom, Hering adds, the physician should never be content with this alone but must search out all possible co-symptoms as otherwise his judgment of the functional disturbance of the heart will be too one-sided.

93. **Tests of Liver Function.**—Strauss states that continued research and further experience have confirmed in every particular his assertions twelve years ago in regard to the importance of alimentary levulosuria as a sign of defective functioning of the liver. Galactose is also suited for the test, but the dose best adapted for the purpose seems to be 30 gm., while the proper dose of levulose is 100 gm. Each test is made in the morning on the fasting stomach and the elimination in the next six hours is the criterion. He gives tables showing the findings of the test at a number of different clinics. In 127 cases of cirrhosis of the liver the levulose test gave positive findings in 33 per cent.; in 70 per cent. of twenty-seven cases of catarrhal jaundice; in 62.5 per cent. of thirty-two cases of jaundice from obstruction of the common bile duct; in 75 per cent. of twelve cases of jaundice from syphilitic lesions, and in 38 per cent. of forty-two cases of tumors. On the other hand, the findings were positive only in 14.8 per cent. of 175 cases in which the liver was presumably sound. The galactose test, on the other hand, seems to be more sensitive in cases of functional disturbance of the liver, of nervous origin. The latter test has not yet been applied with uniform technic in a sufficient number of cases for a true estimate of its value.

95. **Internal Treatment of Exophthalmic Goiter.**—Becker has recently reexamined seven patients who were cured by internal treatment several years ago. He found that the benefit had been permanent and all seem to be in good health. These were the most interesting cases among sixty-one patients with exophthalmic goiter out of over 40,000 patients of all kinds admitted to the hospital at Giessen since 1890. The experiences related confirm the wisdom of a few months of conservative treatment with rest, tonics and specific measures before an operation is contemplated after failure of the above.

97. **Recovery from Tetanus Neonatorum.**—The tetanus developed in the case reported by Wolff in a child 9 days old, and benefit was derived from serotherapy and large doses of chloral, with final complete recovery. The tetanus antitoxin was injected in the vicinity of the umbilicus at first, the next day subcutaneous, and the third day half subcutaneous and half intramuscular. The total dosage was 300 units. The chloral was given by the rectum, 0.5 gm. as the daily dose. This is larger in proportion than the maximum dose for adults; one day this dose was given at each of the three feedings. Feeding was possible only through the stomach tube with the child under the profound influence of the chloral. The eighth day no chloral was given, only 0.5 gm. bromid, but the chloral had to be resumed again the next day in order to feed the child. By the eighteenth day the dose had been gradually reduced to 0.25 gm. chloral, and by the twenty-seventh day natural feeding could be resumed and all drugs were dropped. The child recovered rapidly and seems normal. Recovery from tetanus neonatorum is so rare that Wolff thinks this method of treatment which protected the child from exhaustion from the convulsions while permitting adequate nourishment certainly was instrumental in the cure.

100. **Treatment of Chronic Frontal Sinusitis.**—Pick has been remarkably successful in treating frontal sinusitis of long standing by twenty-minute sittings every day in negative atmospheric pressure supplemented by inhalation of an epinephrin spray. The negative pressure in the air passages aspirates the contents of all communicating cavities, and relieves congestion in them.

108 Method of Testing the Skin Reaction to Chemical Stimulation. (Die Prüfung der Hautreaktion auf chemische Reize.) J. H. Schultz.

103. **Etiology of Scarlet Fever.**—The cause of scarlet fever has never been definitely determined and the attempts to transmit it to monkeys have met with only very limited success. Kretschmer believes that it is a streptococcic infection, though this assumption has not been proved or disproved with certainty. Many clinical facts seem to prove that a special susceptibility on the part of the patient is an important factor in the development of scarlet fever, and that it may be regarded as an anaphylactic reaction to a streptococcic infection. The question of nutrition in the prophylaxis and treatment of scarlet fever deserves more attention than it has previously received. Overnourished and obese children are particularly susceptible to the disease. In treatment a mixed diet is preferable to a milk diet.

106. **Summer Heat and Infant Mortality.**—Rietschel maintains that, aside from its indirect effect in spoiling the milk, the high temperature in summer has a direct effect on the child's health. This may be acute, manifesting itself in coma, cramps, fever, diarrhea and vomiting, or it may be chronic, lowering the child's resistance and bringing about various changes in the organism, such as reducing the fermentative processes in the intestine, affecting the intestinal flora, changing the water content by increased perspiration and thus increasing the danger of skin and other infections. There is likewise danger of overfeeding on account of the child's increased thirst. Clinically we get all kinds of pictures, from acute intoxications to chronic summer diarrhea, with or without infection. To be sure, poverty, lack of fresh air, sunlight and proper care are factors in the production of these diseases, but all these causes exist in the winter also, and the excess of the summer over the winter mortality is to be attributed solely to the effect of heat which aggravates all the other disease-producing agents.

107. **Value of the Coin Sign in Diagnosis.**—In 1898 Pitres described a sign which he had found valuable in distinguishing between pneumonia and pleural exudate. An assistant strikes two copper coins together over the suspected area. The physician listens with one ear over the symmetrical point on the opposite side of the chest and the other ear covered so as not to get the sound of the coins directly. If there is fluid between the two points, the sound will be transmitted with a metallic clang; if there is normal tissue it will be dull, and if the consolidation of pneumonia is present it will be still duller. From a study of his own cases and those reported in the literature, Ostrowski confirms the diagnostic value of this sign.

110. **Estimation of Working Capacity in Traumatic and Other Nervous Affections.**—Zahn discusses the bases for a medical certificate in the question of workmen's compensation, insisting on the extreme caution necessary. Among the points he brings out is that the question as to the amount of credence that can be given the patient's statements is not a medical question. In many cases a true estimate of conditions can be obtained only by others' spying on the individual elsewhere. Previous records of hospitals and insurance companies affecting the individual may often prove useful. The fact that the individual does not go to his usual place of employment is often assumed as testimony that he is unable to work. The nervous symptoms should be noted, when possible, while the patient does not know that he is being observed. In examining the patient, also, the different nervous disturbances should be studied while apparently studying some other nervous manifestations. Irregular heart action and distribution of the blood, relaxation of the muscles, local swelling and general loss of weight are independent of volition. To this group belong further persisting insomnia, irritability, vertigo, paralysis and contracture. If a disturbance in the motor or sensory sphere grows less when the attention is diverted, simulation is not always responsible for this; hysteria may show such phenomena; even severe paralysis is liable to become attenuated under these conditions. There may be a mental factor in pain from some organic lesion, and the pain may thus let up to a certain extent as the attention is diverted. Zahn has frequently encountered cases of severe constitutional neurasthenia with extreme motor weakness, in which certain automatic movements, such as smoothing the forehead, were done with comparatively little disturbance; in other cases the speech became normal during emotional stress. When the disturbances are predominantly subjective, the medical certificate as to the working capacity had better be conditional.

114. **Electric Treatment in Exophthalmic Goiter.**—Günzel describes his method of applying the intermittent electric current (Leduc's current) in treatment of exophthalmic goiter, saying that the results have been excellent in nearly every case and surprisingly fine in a number. He bases the treatment on the assumption that the trouble is the result of excessive irritability in the sympathetic system. This high frequency interrupted current reduces the excitability of nerves and thus benefits in neuralgia, migraine, angina pectoris, lumbago, sciatica and rheumatoid pains even with a ten or fifteen minute application. This current is able to induce in animals a total general anesthesia. It also has an attenuating and curing influence, Günzel says, on all nervous functional disturbances and this effect is particularly marked in exophthalmic goiter. The positive fork-shaped electrode fits over the goiter and sides of the neck, while the negative is applied to the chest or back of the neck. He states that the nervous excitement, palpitations, insomnia, headaches and rapid breathing subside in the first five to eight sittings; with nine or twelve the goiter and exophthalmos are materially reduced and by the end of the course of twenty or thirty sittings the disease, if not of too long standing, is essentially improved or cured.

126 *Caustic Effect of Silver used as a Prophylactic. (Histologische Untersuchung der Aetzwirkung der Prophylaktika.) C. Credé-Horder.

120. **Rectal Examination during Labor.**—Schlapoberski warmly recommends the substitution of rectal for vaginal examination during labor, as thereby all danger of infection is avoided. Midwives should be taught to make the rectal examination and be warned of the danger of the vaginal method. The skull, the fontanel and sutures, and the breech, if presenting, can be palpated through the rectum and also the mouth of the uterus if the edges are thick. If they are exceptionally thin it may not be possible to determine the condition of the mouth of the uterus exactly, but all the information needed in most cases can be obtained. He has had a much smaller percentage of infections since adopting the method.

122. **Ligation of the Hypogastric Artery.**—Nikolskij describes the work of Tichow and Grammatikati at the surgical clinic in Tomsk. They have practiced ligation of the hypogastric artery over a hundred times, in several cases on both sides at once, without any bad effect on the rectum, bladder or other pelvic organs. It is not difficult technically and greatly facilitates pelvic operations by avoiding hemorrhage. The chief indication for which they have used it is in operating on uterine carcinoma which had previously been considered inoperable. By the use of this method and by implanting the ureters into the rectum they can remove a large amount of peri-uterine tissue, the entire bladder and the lower section of the rectum. They have raised the operability of uterine cancer to 77 per cent. with a mortality of 31 per cent. He gives a detailed anatomic description of the conditions that develop when the ligation is performed.

126. **Effect of Silver Preparations Used in the Eyes of Infants.**—Credé-Horder concludes from a series of histological examinations of material from the eyes of dogs and new-born infants that no harm is done by the use of silver preparations as a prophylactic for ophthalmia neonatorum; the conjunctiva alone was affected and that only in a transitory manner. The cornea was not affected at all. He used as high as five drops of a 1 per cent. silver nitrate solution, and also tested other silver preparations, but they seemed to have less effect than the nitrate. He asked a number of directors of obstetrical and infants' clinics if they had ever seen any permanent injury from the use of silver nitrate, and the answer was always negative. Illustrations are given showing his histological findings.

136 Tuberculin Treatment not Suited for Out-Patients. (Ueber ambulante Tuberkulinbehandlung.) E. Hartmann.

133. **Domestic Animals and Fowls in Etiology of Epidemic Poliomyelitis.**—Bruno relates that recently infantile paralysis developed simultaneously in two young children on a poultry farm near Heidelberg. The children had never left the yard but a number of domestic animals and poultry had the run of the large yard. A consignment of ducks had been received from a distance shortly before, and one was found dead in the yard the seventh day; seven days later another duck seemed to be paralyzed but it continued to eat; after three days it was killed and eaten. Three weeks after the arrival of the ducks two others developed the same symptoms of paralysis and a week later a third, but this last group of three ducks recovered. None of the forty-seven geese and chickens showed any signs of disease. The two children developed symptoms the same day, the thirty-ninth day after the arrival of the ducks. The entire family complained of feeling ill for several days about the same time, mostly with gastro-intestinal symptoms and light fever; one had in addition severe "rheumatic" pains in the back.

Bruno reports in addition a recent case of a child with manifest epidemic poliomyelitis on a farm where a cow had just previously died with symptoms indicating paralysis, and a paralyzed hen was found a little later. On another farm a goat died with symptoms of paralysis and ten days later an isolated case of infantile paralysis developed in the farmer's family. He urges investigation of the domestic animals in all cases of epidemic poliomyelitis. The assumption that the disease can be transmitted by domestic animals, poultry and dogs—possibly merely carriers—would explain the peculiar spread of the disease in rural districts and afford grounds for effectual prophylaxis, both individual and public. He states that Heidelberg seems at present to be the center of a widespread epidemic of Heine-Medin's disease, although the cases are not very numerous.

142 Necessity for Written Directions. (Verordnung stark wirkender Arzneimittel.) W. Heubner.
143 New Regulations in Regard to Trade-Marks. (Entwurf eines neuen Warenzeichengesetzes.) W. Heubner.

137. **Cataract.**—Pagenstecher says that progress of late in regard to cataract has been mainly from experimental research, and he states that the only effectual treatment is still by operative measures. He reviews the various technics and the indications, saying in conclusion that the greatest improvement realized to date in regard to cataract is the continued improvement in eye-glasses. Great progress has been realized in this line.

138. **Operative Treatment of Varicose Veins.**—Tappeiner compares the different methods in vogue and the results, citing a number of articles which have been summarized recently in these columns. At the surgical clinic at Greifswald, where he is assistant, he says they make a point of removing the entire long saphenous vein by Babcock's technic (See THE JOURNAL, 1910, lv., 210). Smaller and larger nodules and varices are removed separately through small incisions when necessary. If Babcock's method is not practicable, Madelung's technic is applied; that is, the enlarged veins are removed in sections from three long incisions. Only in the rarest cases was it found necessary to apply the spiral incision. So far as possible the veins are not attacked until any existing ulcers have healed over under bed-rest and keeping the leg raised, with other measures as needed to ensure that the operation on the varicose veins will be in an aseptic territory.

139. **Treatment of Functional Stomach Disturbances.**—Curschmann warns that there is danger now of going to the opposite extreme and accepting a duodenal or gastric ulcer in every case of stomach trouble when in fact the disturbance may be purely functional. Too much reliance on the Roentgen findings is liable to lead to needless operative interference in some cases, but the assumption of a peptic ulcer as the result of nervous spasm is especially justifiable with stomach disturbances in chlorosis or with habitual vomiting in young girls or women. In differentiating a gastric ulcer from a gastric nervous trouble, signs of a neurotic predisposition by no means testify against a possible ulcer. Bergmann found

a neurotic tendency evident in fifty-eight of sixty ulcer patients. In nearly every instance the neurotic trouble was in the vegetative nervous system, mostly in the sense of vagotony; that is, excessive irritability of the vagus nerve. The local ischemia from spasmodic contraction of the vessels amply explains the development of a peptic ulcer and its inability to heal.

But, notwithstanding all these undoubted organic cases, Curschmann insists that we must not fail to recognize that there are some purely nervous dyspepsias which must be treated as a neurosis. The trouble in these cases is the reaction of the digestive apparatus to a nervous trouble with a pronounced mental factor, a psychoneurosis. Either stomach or intestines may be involved, but the mental-nervous trouble affects most frequently the stomach almost exclusively. He calls attention in particular to the cyclic type as a particularly frequent and important form hitherto generally overlooked.

Periodically recurring forms of mental and nervous disturbances are often disregarded by practitioners as they so frequently lack the time or do not feel the necessity for mastering psychiatric matters which have come up "since their day." This is especially to be regretted—particularly from the therapeutic standpoint—in respect to these periodically returning psychoneuroses. Curschmann has encountered many cases of cyclothymia in which the complaints and the entire case-history bore exclusively on digestive disturbances. The recurring anorexia and rebellious constipation had been treated with course after course of lavage of the stomach, oil enemas and dieting. That these measures must necessarily fail is obvious. The mind, not the digestive tract, is what requires treatment. Careful study of the history of the case will bring out the cyclic character of the nervous trouble and its mental basis, and warn against these unnecessary measures.

Curschmann adds that the newer diagnostic measures are having such a vogue that the most elementary basis for the diagnosis, the previous history of the case, is being culpably neglected by many modern practitioners. He describes some cases which illustrate the importance of the somatic diagnosis for psychic treatment. The first patient was a woman of 46, unmarried, with long recurring attacks of constant vomiting. Anacidity and lactic acid were found in the stomach content after a test breakfast, and the assumption of cancer seemed to be justified. From a child she had had a "weak stomach" and periodical headaches. The advised exploratory laparotomy was refused, and the condition began to improve. After a month or so Curschmann gave her a test "appetite meal," allowing the patient to eat her favorite dish. The stomach content after this test-meal showed approximately normal findings. The case was evidently one of recurring stomach equivalents of migraine. The vomiting kept up after the headache subsided or occurred in place of the migraine. These equivalents of migraine have to be differentiated from cholelithiasis and other colics of the stomach and tabetic crises. The history of the case will reveal the transformation of the original periodic, one-sided headache into the stomach equivalent, the vomiting center having been trained to react to slight irritation. Curschmann discussed her case with the patient, explaining the above, and insisting that there was no actual stomach disease and that she could eat according to her appetite. He sought to persuade her according to Dubois' principles of persuasion psychotherapy, and finally did convince her that she had no need to fear trouble from her stomach, and almost at once she was cured. She has been free from all disturbances for three and a half years now to date, except that she still has occasionally a mild sick headache.

Curschmann emphasizes the importance of a test "appetite meal" in the estimation of the anacidity of the morbidly nervous. The findings may confirm the fickleness of the gastric secretion in these circumstances. The assumption of the benign character and the origin in the mind of the disturbances are confirmed by the results of mere psychotherapy, reasoning with the patient, and proving to him by the actual stomach findings the harmlessness of the functional disturbances and that his stomach is not so weak as he (and, no less, his attending physician) had supposed. The food must be served in an appetizing form, the stomach secretion reacting most energetically to food which the patient enjoys.

Persuasion fails when there is some compelling idea or memory which checks stomach functioning. The gastric disturbances in these cases resist treatment until this obsessing memory is rooted out or conquered. Curschmann reports three cases of this kind. In one an unmarried woman had had no appetite for some months and became nauseated at the sight of food. After the failure of ordinary measures, Curschmann applied psychanalysis to a certain extent, groping back in the past to find some cause for her nausea, and it was readily discovered. She had waited on a consumptive whose coughing often sprayed the food with sputum, and after the death of this woman she had lived in a family which kept several untidy cats. The sight of food afterward recalled the consumptive and the odor of the cat droppings, and Curschmann to dispel this memory-obsession applied light hypnosis. Improvement followed the first sitting and complete recovery the second. In two other cases he cured with hypnosis a similar chronic disgust-nausea developed from an unfamiliar diet; by a curious coincidence, one patient acquired the neurosis during service in a Jewish family, disliking the kosher food, while the other, a Jewish young man, developed it in a non-Jewish boarding house from the lack of his accustomed kosher diet. Curschmann regards these rebellious alimentary obsessions in adult neuropathic persons as the essential field for hypnosis. He applies it according to Forel's principles. The indispensable condition for success, however, is to dig into the past to ascertain the true cause of the obsession.

Wiener klinische Wochenschrift, Vienna

September 11, XXVI, No. 37, pp. 1439-1484

144 Radium in Dermatology. G. Riehl and M. Schramek.
145 *Resistance of Local Foci of Spirochetes to Combined Treatment of Syphilis. F. Fischl.
146 *Radium and Mesothorium Treatment of Cancer. O. Schindler. Commenced in No. 36.

145. **Resistance of Spirochetes in Local Foci.**—Fischl reports the local findings in three cases after most thorough combined treatment of the constitutional syphilis and local mercurial treatment of the local foci. The spirochetes in the foci persisted apparently not much modified by all these measures, and after the mercury and salvarsan have been eliminated from the body, the spirochetes still lurking in the focus may rouse to ravage anew. His findings in these and other cases confirm the importance of excising or at least destroying the early foci. When spirochetes thus escaping treatment sally forth anew, the consequences may simulate reinfection.

146. **Radiotherapy of Cancer.**—Schindler describes his experiences with radium and mesothorium in various types of malignant disease, all confirming the advantages of large doses well filtered. The effect seems to be identical with the filtered radium and mesothorium rays; they have greater penetrating power than the Roentgen rays, while the technic of the application of radium and mesothorium is far simpler and infinitely more convenient than Roentgen-ray exposures.

Zeitschrift für Kinderheilkunde, Berlin

VIII, No. 5, pp. 363-442. Last indexed Sept. 27, p. 1083

153 Energy Quotient of Breast-Fed and Artificially Fed Infants. I. Engel and S. Samelson.

148. **Congenital Tuberculosis.**—Zarfl cites cases from the literature in which tubercle bacilli have been demonstrated to have passed with the mother's blood through the placenta to the fetus. He describes in detail a case of his own, an infant

born of a tuberculous mother. On the seventeenth day of its life, the Pirquet reaction was markedly positive, showing, he says, that the infection must have taken place in intra-uterine life, as such a sensitiveness to tuberculin could not have developed in seventeen days. On the eighteenth day there was enlargement of the spleen and liver. The swelling of the spleen increased and was the most prominent symptom throughout. Up till the last week there was no clinical or Roentgen-ray evidence of lung involvement. The child died on the fifty-second day of its life and autopsy confirmed the assumption of blood-borne infection from the mother as the lymph-nodes of the liver region were the ones most seriously involved, and there was only slight involvement of the bronchial lymph-nodes, while no focus could be demonstrated in the lungs. Ghon and others have shown that in tuberculosis acquired after birth there is practically always a primary focus in the lung. The mother lived three months after the birth of the child.

155 *Transplanting Hair-Growing Skin. (Zur Frage der Ueberpflanzung behaarter Haut.) V. Perimoff.

155. **Transplanting Part of the Scalp.**—Perimoff reports the case of a man with a deforming cicatrix in the right side of his head, who made an arrangement with a Mohammedan for a transplanting operation, paying the latter for a part of his scalp; Mohammedans always keep their heads covered. Both were anesthetized with chloroform at the same time. The cicatricial area was cut out down to the periosteum and was replaced with the flap from the other scalp. It healed perfectly in place, the hairs did not fall out and continued to grow apparently normally. The areas had been cleaned only with soap and warm water, and Perimoff thinks that the failure of others in similar operations may have been due to the over-vigorous sterilization of the graft. The skin of dogs does not fit to the scalp so well.

161 Diabetes Insipidus; Two Cases; Recovery Under Hypophysis Extract Treatment. F. Francesco.

160. **Importance of Abstention from Lime in Management of Arteriosclerosis.**—Scandola's long article confirms the importance of lime as a factor in disease of the arteries. Also that with existing disease of the arteries there is *notable* retention of calcium on an ordinary diet, while nothing brings such profuse elimination of calcium as to abstain from it in the diet. When foods are used which contain merely minimal proportions of calcium, the elimination is greater than the intake, and this is an important element in treatment of arteriosclerosis. He gives some data showing that bread, meat, potato and rice contain comparatively little calcium. In his research he found the figures respectively 0.04312, 0.69358, 0.01476 and 0.05432 gm. per 100 gm. Cheese, milk, eggs and beans contain large proportions of calcium. He gives illustrations showing the findings in the arteries of dogs fed systematically with calcium, and reports other research of his own and others, reiterating that a calcium-free diet has a greater effect on the elimination of calcium than any drug known.

165. **Neuroses among Telephone Girls.** — Fumarola and Zanelli report nine cases encountered at the university clinic for nervous affections at Rome. In nearly all the cases there was a history of nervous disturbances in previous years, before taking up the telephone work. The neurosis in all seemed to be of the cerebral type of neurasthenic hypochondria, associated with anxiety, dread and vasomotor disturbances. The prognosis is good in the early stages if the patient can change her occupation. In cases of long standing, recurrence under the same conditions is almost inevitable. The work requires manual skill and accurate vision, and is a constant strain on the hearing; the entire organism thus participates in the work and during certain hours of the day there is not a moment for rest. Add to this the vibrations of the receiving membranes and the repeated electric shocks and it is easy to understand that a predisposed nervous system is unable to stand the strain. Iron and arsenic were found useful and gelsemium and solanin for the nervous system, but the most important measure was abstention from the telephone work for a time at least. The bibliography on the subject is appended.

180. **Cataract and Internal Secretion.**—Schiøtz gives an illustration of a calf with congenital *goiter*, cataract and various signs of cretinism, and he *theorizes* and presents numerous arguments to sustain the assumption that the internal secre-

tions play an important part in the pathogenesis of certain forms of cataract. It has already been established beyond question, he states, that parathyroid insufficiency may lead to cataract. Other conditions which *may* contribute to cataract are insufficiency of the pancreas and sexual glands with excessive activity of the adrenals, hypophysis and thyroid. He thinks it is now established that cataract in many cases is an evidence of *auto-intoxication* (for example, tetany and diabetes), or of extraneous poisoning (ergot, naphthalin). The aim of his present communication is to emphasize the important part which must be ascribed to the functioning of the ductless glands. It is not a mere coincidence that Bunau found that 10.6 per cent. of all the *cataract* patients at the Halle eye clinic had had typhoid fever at some time. Mann this year reported the case of two brothers who developed first cataract and then myotonic and myotrophic symptoms with, later, signs of tetany. Hippel has also recently reported the case of an infant with double cataract whose serum responded positively to biologic tests with thyroid and adrenal tissue and with this alone. Gebb has also found a difference in the response to the biologic tests in the serum of persons with and without cataract.

182. **Acute Dilatation of the Stomach.**—Borchgrevink had a patient of 53 with symptoms of acute dilatation of the stomach growing constantly worse during two weeks in spite of all his measures. This was in 1910, and turning to his library for help, he found in Moynihan's book the statement—"In my *cases relief* has always been given by changing the position of the patient. He must be placed prone in bed." He at once had his almost moribund patient turned on her stomach and lo, at once she was cured. The same dramatic change in the clinical picture was observed in a second case, and he reports three others from Bull's practice, *and reviews from the literature* 142 cases of acute dilatation of the stomach. He tabulates all this material, grouping the cases as treatment was with lavage alone, with operation, or with merely a change to the prone position or to the side with the pelvis raised. The *mortality in* the 142 cases was 54.9 per cent., but in the later series, the mortality has dropped to 26.9 per cent. of 70 cases. Of the thirty-one patients treated by medical measures alone (excluding position treatment), twenty-nine died; one recovered under large doses of sedatives, and one under continuous saline infusion; the trouble was not correctly differentiated in this case. Some in this group died in a few hours, others after a few days; Herrick's patient the twelfth and Kausch's the sixteenth day. In Sommarin's case, radioscopy showed the stomach still *reaching* 3 cm. below the umbilicus a month later. In the operative group only five of the twenty-three patients survived, one treated by gastro-enterostomy, one by gastrostomy, and three whose stomachs were evacuated by a laparotomy. The results were *poorest with gastrostomy, only* one of the eleven patients recovered. Change to the prone *position* cured twenty of the twenty-four patients; it seemed to aggravate conditions in Borchardt's case, and no benefit resulted in two others; the diagnosis was not certain in these latter cases. Reclining *on the* side with the pelvis raised *proved* effectual in three cases.

Imprudence in eating or drinking or both was manifest in forty-one of the total 142 cases, and this probably occurred in a still larger proportion; in fact, this was especially evident in the postoperative cases. The patient and nurse in other cases *may* not have acknowledged the indiscretion. The arteriomesenteric occlusion is probably secondary to the dilatation of the stomach. Borchgrevink explains the latter as due to the disproportion between the functional capacity of the organ and the work demanded of it. The stomach does not suffer more than other organs from the effect of the general anesthetic, the debility, etc., but *it* is the one organ on which demands are made almost at *once after a major* operation, etc., and if these demands are beyond its functional capacity at the moment the stomach simply abandons the attempt to respond to them. Effectual prophylaxis is thus only a matter of prudence in making demands *on* the organ until it has regained its normal tone after operations, and refraining from extreme overloading of the stomach.

183 *Diagnosis and Treatment of Chronic Juxtapyloric Ulcer. (Bidrag til Mavesaarets Patologi og Terapi, II.) S. Kemp.

183. **The Juxtapyloric-Ulcer Syndrome Has Been Mistakenly Credited to Duodenal Ulcer.**—*Kemp's* article issues from the clinic in charge of Faber and may be regarded as a supplement to Faber's article summarized in The Journal, Feb. 22, 1913, p. 638. The details are tabulated of thirty-seven operative cases of juxtapyloric ulcer in stomach or duodenum and of four others with cancer. This material is studied from the point of view of the question as to whether it is possible by clinical examination alone to determine positively the existence of a juxtapyloric or duodenal ulcer. Of the more important symptoms—digestive or continuous hypersecretion, spasm of the pylorus, retarded evacuation of the stomach, occult hemorrhage, and a small amount of residue after twelve hours—the first two are encountered almost exclusively with the *juxtapyloric type of chronic* ulcer while the three others belong to the clinical picture of chronic ulceration in the stomach in general, regardless of its location. Yet even these symptoms occur with peculiar constancy with the juxtapyloric ulcers.

Kemp says that with all due credit to the writers who have turned the lime-light of attention recently on duodenal ulcer, their work must be regarded as a step backward rather than forward, for time has shown, he insists, that the syndrome they have *emphasized does not belong to duodenal ulcer* but to juxtapyloric ulcer, regardless of whether the ulceration extends down into the duodenum or up into the stomach. Periodicity of the disturbances is not peculiar to duodenal or juxtapyloric ulcers but is observed with other stomach affections at times, intervals occurring in which all the symptoms may disappear. Tardy pains may occur with affections other than ulcer. There is danger that the subjective symptoms will be given too much weight in diagnosing and that the physician's *mode of questioning may suggest to the patient* the answers that are anticipated, especially in regard to the subjective symptoms, and among these the tardy pains in particular. Previous examinations by other physicians or the conversation of other patients may *afford suggestions that will unconsciously modify the patient's statements* as to the present status and the history of his case. Two cases in particular are cited to impress this lesson; both patients complained persistently of symptoms assumed to be due to a duodenal ulcer and both were operated on. *Necropsy in* each case *revealed merely an old, healed* gastric ulcer; the subjective symptoms of the ulcer had persisted, reenforced by neurasthenia, and notwithstanding the normal objective findings gastro-enterostomy had been done in each case. The patients were men of 25 and 37, and *both died* a few days after the operation, demonstrating anew the dangers of a diagnosis based on the patient's complaints alone.

In conclusion Kemp reviews the history *of the* science of diagnosis of gastric ulcer, and states that an *ulcer may* be assumed either (1) when *there are periodical,* tardy pains (vomiting), excessive gastric secretion and occult bleeding; (2) periodic tardy pains (vomiting), *hypersecretion* and small retention after twelve hours; (3) periodic *tardy* pains (vomiting), hypersecretion and spasm of the pylorus; (4) hypersecretion, *occult bleeding* and small twelve-hour retention; (5) hypersecretion, motor insufficiency of the first degree, and small twelve-hour *retention;* (6) hypersecretion, spasm of the pylorus and small twelve-hour retention, or, (7) attacks of spasm *of the pylorus* and occult bleeding. With ulcer, the spasm of the pylorus *causing* the pain relaxes after the stomach has been emptied, while with *cholelithiasis* the pylorospasm is a minor element in the general contractions. This point is useful in differentiation.

Determination of the juxtapyloric site of the ulcer is of paramount importance for the reason that a *simple* gastro-enterostomy is all that is needed, as a rule, in these cases. With ulcer elsewhere in the stomach, resection is *generally* the only measure available for permanent relief.

SOME NEWER METHODS OF REDUCING THE MORTALITY OF OPERATIONS ON THE PELVIC ORGANS *

GEORGE W. CRILE, M.D.
CLEVELAND

Since the inauguration of the aseptic era the mortality-rate in abdominal operations has been falling steadily and to-day there are practically no deaths from simple abdominal operations for conditions unaccompanied by organic disease or infections.

This reduced mortality-rate is due in part to an improvement in technic, but very largely to the exercise of an increasingly critical judgment on the part of the surgeon in his selection of cases.

The technic has become standardized for such routine operations as the removal of benign tumors of the pelvic organs and for operations for chronic pyosalpinx, procidentia, prolapsus uteri, etc. The rare fatalities which occur in these apparently favorable cases result from some unforeseen and as yet uncontrollable factors such as embolism.

The results secured by the individual surgeon have come therefore to depend on two factors: his mastery of general operative technic and his policy in the selection of cases for operation.

The reclamation of the handicapped patient, however, has been and is one of the most cogent surgical problems. Mortality-rates would indeed be high were they based only on operations on patients with hypertension or hypotension, the result of infections or organic diseases; but I believe that even in these cases patients may be operated on successfully, not only without fatal end-results, but without the familiar train of disastrous sequelae, so disheartening to patient and surgeon alike.

If operations on handicapped patients can be postponed safely, the underlying causes of the hypertension or hypotension may often be combated successfully. Physiologic rest, diet and special therapeutic measures may avail to bring the patient to a condition in which operation may be safely attempted. The handicapped patient has been searchingly studied by the able chairman of this section, Dr. Simpson.

Our problem is (1) to discover what may be the special risks when operation cannot be postponed; and (2) to evolve means by which those risks may be obviated or minimized.

The natural sequelae in hypertension cases are embolism, thrombosis, renal insufficiency, angina, pneumonia and cardiac failure. The same train of disastrous results may be seen in persons with hypertension who have been injured in accidents, and also in physically uninjured persons who have undergone some severe psychic shock. Since both psychic and physical strains produce identical results in patients with hypertension, it would seem that the seat of danger must be found at the final point of meeting of both psychic and physical impressions—that is, in the brain tissue.

A long series of laboratory experiments on animals subjected, some to emotional excitation, and others to physical trauma under anesthesia, showed that identical brain-cell changes were caused in each case. That is, both physical and psychic stimulation exhaust the physical substance of the brain cells. *Emotional stimulation* not only causes brain-cell deterioration, but produces also an increase of the internal activating secretions—epinephrin, thyroid secretion, glycogen—a vital point in cases of hypertension.

A logical conclusion from these experiments was that if an operation could be so performed that no traumatic impulse could reach the brain, and if in addition all emotional stimuli connected with the operation could be removed or reduced to a minimum, then the dangers of operation would be those only which would result from the local injury inflicted. Brain-cell exhaustion would be prevented, as would the disastrous effect of the presence in the body of increased amounts of the energizing products of internal secretions.

TECHNIC

From these premises I have evolved an operative method which I have named anoci-association because by its use all nocuous, or noci-associations are cut off from the brain. The complete operative procedure under this principle includes a lessening of the pre-operative psychic strain by the administration of solacing drugs; the administration of a general inhalation anesthetic to obliterate harmful impressions in the course of the operation; the progressive use of a local anesthetic to prevent the passage to the brain of traumatic stimuli from the field of the operation, and finally the use of a local anesthetic of lasting effect that the tissues may be kept relaxed and that painful after-effects may be eliminated or minimized.

In such an operation the brain cells have been subjected to no exhausting strain from painful impulses received through contact ceptors; and since the special senses have been closed to all impressions no psychic stimuli have reached the brain, so that the energizing organs in turn have not been pushed to increased activity.

From an operation conducted after this technic the patient with hypertension will emerge not only no worse for the experience, but it may be in actually better condition, because the body and brain have been so completely at rest.

---

The same technic avails also for the patient with hypotension whose brain cells are already weakened and exhausted by the anemic condition. In hypotension we have a definite and efficient remedy, for the condition is logically to be met by direct transfusion of blood; as occasion demands, this may be done several days before, just before, during the operation, or immediately thereafter. In these cases of hypotension, however, the margin of safety is much reduced, for some brain cells may have deteriorated from exhaustion beyond the power of resuscitation by rest or transfusion, so that it is of vital importance so to perform the operation that the already diminished resisting powers of the patient may not be further depleted.

In addition to the psychic and traumatic dangers in operations on handicapped patients, one other operative factor—the anesthetic—should receive most careful consideration.

Ether anesthesia has certain advantages. It is relatively safe in inexperienced hands; its bulk is small; it is inexpensive; it requires the simplest apparatus for administration. Against ether, however, stand certain effects, objectionable always, but of peculiar danger to patients with hypertension. However skilfully it may be administered it always induces a period of psychic stress in the earlier stages of its administration; the strain of ether nausea and vomiting is especially dangerous in these critical cases which we are considering; the dose of ether required to dissolve the lipoid in the brain sufficiently to cause anesthesia dissolves also the lipoids in the liver, the kidneys, the red blood-corpuscles and other important structures. Ether also chemically hinders or prohibits phagocytosis; hence it may produce nephritis and pneumonia, and, of vital importance in hypotension cases, anemia. Ether immediately impairs the immunity of the patient so that infections find a ready recipient.

I have therefore made nitrous oxid the anesthetic of choice, because it is devoid of harmful after-results, and serves as a measurable protection against shock, since by its hindrance to oxidation it diminishes brain-cell changes—a fact which I have established experimentally. It is an expensive anesthetic and should be given only by a specially trained and skilful anesthetist, objections which can have no weight as compared with the resultant advantages to the patient derived from its use.

The complete technic in abdominal operations is as follows: When the preoperative strain is great, an hour or so before the operation the patient is given a hypodermic injection of 1/6 grain of morphin and 1/150 grain of scopolamin, that he may receive the solace and quiet which come from the use of these drugs. In exceptional cases the inhalation anesthetic may be administered in the patient's room; or else, in the apathetic state produced by the morphin and scopolamin, the patient is conveyed gently to the operating-room, where a specially trained anesthetist administers nitrous oxid. When the patient is anesthetized the division of tissue is preceded by nerve blocking by means of the local administration of 1:400 solution of novocain. Each division of tissue in the course of the operation is preceded by the infiltration of this local anesthetic, the block being made so complete that no nerve is left free to carry a single activating impulse to the brain. First the skin, therefore, then the subcutaneous tissue, then the fascia, and finally the remaining muscle or posterior sheath and the peritoneum are in turn novocainized, subjected to momentary pressure to spread the anesthetic, and then divided within the blocked zone. If the blocking has been complete, then on opening the abdomen there will be found no increased intra-abdominal pressure, no tendency to expulsion of the intestines, and no muscular rigidity.

The peritoneum is next everted and a 0.5 per cent. solution of quinin and urea hydrochlorid is infiltrated about the line of proposed sutures; and, as before, the parts are then subjected to momentary pressure. This infiltration serves as a block, and as its effects last for several days it should prevent or at least minimize the postoperative wound pain and the postoperative gas pain, and by so much minimize postoperative shock. The quinin and urea salt causes a certain amount of edema of tissue, which lasts for some time after the wound is healed. The relaxed abdominal wall will permit exploration of the entire abdominal cavity with ease. If there is no cancer or acute infection in the field of operation, then the following regions may be blocked as completely as, and in the same manner as, the abdominal wall, namely, the meso-appendix, the base of the gall-bladder, the uterus, the mesentery and any portion of the peritoneum. In performing a hysterectomy the broad and round ligaments are thoroughly infiltrated with novocain before they are severed, and again before the wound is closed the stumps may be completely infiltrated with quinin and urea hydrochlorid, thus giving a degree of anesthesia for at least two days. On account of the absence of nociceptors, operations on the stomach and intestines made without pulling on their attachment cause no pain, and hence the novocain infiltration of these viscera is not required. If the brain has received no stimuli during the operation, then the closure of the upper abdomen is as easy as the closure of the lower; all is done with the ease of relaxation.

What is the result? No matter how extensive the operation, no matter how weak the patient, no matter what part is involved, if *anoci* technic is perfectly carried out the pulse-rate at the end of the operation is the same as at the beginning. The postoperative rise of temperature, the acceleration of the pulse, the pain, the nausea and the distention are minimized or wholly prevented.

RESULTS

I have described the complete anoci operation. What is its effect on the postoperative conditions—the morbidity and the mortality? Let us take each morbid manifestation in turn.

1. *Postoperative Pain.*—Quinin and urea hydrochlorid wholly prevents pain if it is injected into the entire wound. But quinin and urea cause some edema of the wound; hence one should limit the wound infiltration to cases needing it, that is, bad risks generally.

2. *Postoperative Gas Pain.*—This baffling phenomenon may be largely or wholly prevented by the technic described, that is, by the hypodermic infiltration with quinin and urea hydrochlorid of a wide margin of tissue, including every part of the divided peritoneum. The stitches must be inserted within the blocked zone. Postoperative gas pain can be explained as a biologic adaptation to overcome infection. In the course of evolution all abdominal penetrations are infected, but the peritoneum is able to overcome most infections if they can be localized. To localize an infection the intestine and the abdominal wall must be kept fixed against each other; that they may do so each must be inhibited; the intestine must be distended with gas, the abdominal wall must be rigid. If the intestine be distended with gas and fixed, then digestion must cease. If digestion be arrested then there is anorexia, or even vomiting to expel food from the stomach. This shows us how postoperative gas pain is due to a biologic adaptation to overcome infection, and

explains its resemblance to incipient peritonitis. Nature does not depend on the surgeon or perhaps she knows the surgeon too well. The test of this hypothesis is easily made. If the brain, through which this adaptive response is made, is kept in ignorance of the incision into the peritoneum (*a*) by progressive novocain blocking throughout the operation and (*b*) by postoperative quinin and urea blocking to prevent later communication with the brain through stitch tension, then there should be no gas pain. Clinical experience has abundantly confirmed this hypothesis. It must be remembered that if a single nerve filament escapes the block there will be gas pain.

3. *Painful Scar.*—I postulate that the lesion of a painful scar is in the brain, not in the scar; that it is due to the low threshold produced by injury, and is intimately connected with a fundamental principle of nerve conduction. This fundamental principle relates to the fact that a strong traumatic or psychic stimulus produces some change in the conductivity along its cerebral arc, the effect of which is that of lowering the threshold of that arc. This might be illustrated by the phenomena following a hold-up at the point of pistol at a street corner. For a long time after such a psychic stress any association with that particular corner would recapitulate the experience. In this manner throughout life the various experiences may lower the threshold in innumerable ways. I assume that there is a similar result after a traumatic stimulus. The arc receiving the stimulus suffers a lowered threshold and hence from that time on mere trifles become adequate stimuli. Such a result is seen in the sensitiveness after fractures and in the painful stumps of crushed limbs. Now, if an operation is so performed that no strong stimulus reaches the brain either during or after the operation, then the thresholds of the cerebral arc from the wound will not be lowered. Since the threshold is not lowered, contact with the scar or any injury to that part will have no more effect than will contact with any other part of the body. In other words, the scar will be no more sensitive than is the skin elsewhere. Hence we see how painful scar may be prevented by complete anoci. Clinical data seem to support this hypothesis, although it has not as yet been fully worked out.

4. *Nervousness.*—When in the night one is threatened with an unknown danger, the brain threshold is always lowered, apparently as an adaptation to the more swift and accurate detection of the danger. Likewise, when one has received a crushing physical injury there is a universal lowering of the threshold. During these states of tenseness minor stimuli have major effects, or, in other words, one is "nervous."

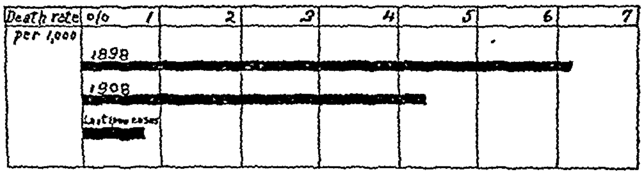
Now, as we have seen, the subconscious brain is tortured directly during unblocked operations under inhalation anesthesia. The resultant general effect on the brain thresholds is demonstrably the same as if the injury had been inflicted without anesthesia, that is, after the punishment of the subconscious mind during an operation the patient emerges "nervous" and "exhausted"; and since a low threshold is lavish in its waste of nervous energy, recuperation is slow. Hence there results a period of postoperative nervousness, of postoperative loss of efficiency. It is obvious, and clinical experience abundantly proves this, that the threshold is preserved by complete anoci; hence the unpleasant, damaging postoperative phenomena are avoided.

5. *Aseptic Wound Fever.*—Since it is a physical law that any form of force may be converted into heat, and that heat thus produced, if not at once transformed into motion, must increase the temperature of the body affected, we see readily why any stimulus, mechanical or physical, which normally would increase motor activity, must cause a rise in temperature if complete motor expression is impossible. Anything, therefore, that drives the motor mechanism of the body beyond the point of normal expression will cause fever. Anger, athletic contests, fear, physical injuries, all produce a rapid oxidation of certain body compounds too great for complete translation into motion.

In operations under general anesthesia only, we expected routinely to see some postoperative rise of temperature as a result of the suppressed power of motor response to the physical and psychic injury; but by the use of anoci-association, both during and after the operation, I discovered no change in the postoperative temperature and pulse-rate. I therefore was forced to the conclusion that, barring infection and the absorption of hemoglobin, postoperative fever is the result of increased oxidation, this being in turn the result of the psychic and traumatic stimuli of the operation to which the natural response had been denied.

So much for the postoperative morbidity. Not only does the surgeon, but also the patient, the intern and the nurse corroborate the story.

As for the mortality-rate, hospital statistics abundantly verify our conclusion. At the Lakeside Hospital since the introduction of this method, my associate, Dr. W. E. Lower, and myself have performed 250 pelvic operations, with but two deaths, a mortality-rate of 0.8 per cent.



Comparative mortality rate of the Lakeside Hospital Service. The first line shows the mortality rate when the hospital was first opened in 1898. The second line shows the mortality rate for the year before the anoci technic was introduced. The last line shows the mortality of the last 1,000 patients operated on at the Lakeside Hospital by the resident staff, Dr. Lower and myself.

Although my purpose in this paper is to deal only with pelvic operations, a word may be added regarding the application of this principle in a general surgical practice. Last year Dr. Lower and I performed 729 abdominal sections of every grade with a mortality-rate of 1.7 per cent., and in the Lakeside Hospital service, where all kinds of acute emergencies are met, and where most of my own private work is done, there were performed by my associates and me in the past year operations on 2,672 patients with a mortality-rate of 1.9 per cent.—a result never before approached in that hospital. In the last thousand operations performed by Dr. Lower and myself, these operations including every risk in a general surgical practice, the mortality-rate has been 0.8 per cent.

Osborn Building.

ABSTRACT OF DISCUSSION

Dr. Henry O. Marcy, Boston: The matter presented shows clearly that the dynamic energy of the individual is the thing to be preserved. While a student in London, in 1870, Sir James Paget said to me, "Dr. Marcy, do you know how to give ether?" They had had twelve deaths in the city from chloroform in the previous six weeks, and I had the opportunity of administering ether, the first time, he said, that it was ever given in London. I gave it after the old-fashioned method which we were taught in the Massachusetts General

Hospital and submerged my patient, but, fortunately, not to her death. Fifty years ago we gave chloroform in the U. S. Army, but it was given carefully and there were comparatively few accidents. When we give alcohol — and ever remember that ether is an acute alcoholic poison — we must know that we are lessening the dynamic energy of life, that we are lessening the circulatory power, and, consequently, lowering the resistance of the patient. Thus, it behooves us, in whatsoever way we give an anesthetic, to remember, first, the emotional conditions of the patient himself, and then study carefully the conditions before we operate as well as during the operation.

Dr. C. O. Thienhaus, Milwaukee, Wis.: I should like to ask Dr. Crile whether or not he would think it advisable to use the injections for the purpose of producing local anesthesia in cases of extra-uterine pregnancy with acute hemorrhage? I believe that for such cases the operation in the so-called "exciting stage of ether anesthesia" is the best method because it saves time. I feel furthermore that the fact is much overlooked that it is entirely wrong to transport these patients to a hospital. They must be operated on at home as rapidly as possible. Some of these patients who are almost pulseless hardly need any anesthetic at all and still, by prompt interference, quite a few of them have been saved, as can be shown by statistics.

Another fact ought not to be forgotten, and that is that the severest cases of general peritonitis following perforations, as well as the severest cases of internal hemorrhage never reach a hospital and, therefore, are not included in the statistics of hospital surgeons.

Dr. Arthur E. Hertzler, Kansas City, Mo.: There are wo points which I should like to bring out: (1) the short ration of novocain anesthesia—not over fifteen minutes. short to be of much use as a block; (2) the question of yperesthesia in the regions anesthetized. In the use of a ocal anesthetic we obtain an exquisite hyperesthesia which may last for days. If this region is made the object of any rritation by suture or otherwise, it is a constant source of rritation and defeats the purpose. I have been working on this problem ever since my assistant called attention to the value of local anesthesia for the lessening of the pain, and we still have little to offer. In the transversalis and the parietal peritoneum, in which the chief difficulty lies, the nerve-supply is exceedingly complex. The nerves come in external to the fascia of the transversalis and ramify external to the parietal peritoneum. How any one is going to block any particular area and keep from striking a set of nerves around the hyperesthetic area we have been unable to determine. What we have demonstrated is that much can be gained by avoiding the nerve areas in all kinds of traumatism, whether it be by suture, forceps or some other means. It is useless to infiltrate tissues that contain no nerves. I should also like to make a point, particularly for personal information, regarding Dr. Crile's statement that quinin produces edema. We have made a careful histochemical study of the effects of quinin on the tissues, and we have not observed that there is any edema produced. We do get an exudate of a granular fibrin in many instances, particularly if the use is excessive, but have never observed that either cellular or edematous infiltration takes place.

Dr. George Gellhorn, St. Louis: It seems to me timely to point out that spinal anesthesia preeminently belongs among the newer methods of reducing the mortality of pelvic operations. It is this method above all others that fulfils all the postulates of anoci-association. The brain of the patient does not know anything of the operation and consequently there is no shock. I can also confirm Dr. Crile's statement, that, because of the blocking of nerve impulses, gas pain is considerably less after spinal than after ether narcosis. It is not altogether absent, but reduced to a marked extent. I hope that Dr. Crile will define his views on spinal anesthesia in his closing remarks.

Dr. George W. Crile, Cleveland: Replying to Dr. Thienhaus' question: Of course, if one encounters an emergency of any kind, the method is not satisfactory outside of the hospital. That question must be settled on its own merits. One would not feel like abondoning a great surgical principle simply because it could not be applied to patients outside the hospital. I am speaking of patients on which this technic can be carried out. Of course, it is quite important to arrest the hemorrhage early. I am sure we all agree to the remark Dr. Thienhaus made.

All that I can say with regard to Dr. Hertzler's points is that it is a clinical fact that by local infiltration one can anesthetize the abdominal wall or any other tissue, if the work is done carefully and well. If one makes a complete infiltration and applies local pressure immediately, a local anesthesia can always be secured. I do not mind particularly what the ultimate facts are regarding the tissues so long as the end is accomplished. I am glad to have Dr. Hertzler assure us that there is no edema; but, I notice this: Quinin and urea hydrochlorid do produce a certain amount of swelling in the wound afterward, more than any other agent I know of. Novocain does not produce any swelling at all. I wish Dr. Hertzler would tell us how we can avoid the swelling which follows the injections, because these injections give something to our operations which we have never before secured. I am ready to be convinced that spinal anesthesia is a safer form of anesthesia than can be secured by our methods. It is because I have not been sure that spinal anesthesia is the safest that I have gone to the trouble of working out the nerve-blocking system. Considering our remarkably low mortality-rate and our marked control over our patients, I should not be willing to give up this method until I was sure that the substitute would be quite as safe.

CAN RABBITS BE INFECTED WITH SYPHILIS DIRECTLY FROM THE BLOODS OF GENERAL PARETICS?

OBSERVATIONS ON THE RECOGNITION OF THE VIRUS IN THE LATER PERIODS OF THE DISEASE *

WILLIAM W. GRAVES, M.D.
ST. LOUIS

Accepting as postulates that syphilis is a chronic infectious disease and that we have no means of definitely knowing its termination during the life of the infected individual, I proposed in a recent communication[1] the theory of relative tolerance as opposed to that of latency. It seemed to me that a period or periods of relative tolerance for the virus, meaning thereby an excellent, a fair, or a poor resistance of the whole or a part of the organism was a better conception, one more in accord with clinical experience, the natural history of the disease and the results of treatment than that of latency.

Certainly, the modern laboratory aids and clinical refinements now utilized in recognition of the syphilitic justify the assumption of many older and modern investigators that somewhere in the tissues of living individuals the *contagium vivum* exists and justify the hope that means may be found by which it may be readily demonstrated in every period of the disease. Nothing short of the actual demonstration of the virus in the various periods of syphilis can satisfy the exacting demands of clinical medicine or lead to the fullest recognition of the protean manifestations of this scourge of the human race. Since the epoch-making discovery of Schaudinn the demand for means of recognition of the virus either in the blood or other tissues or body-fluids in every period of the disease has become more and more insistent, especially so since it was soon found that the blood and lymph-nodes yielded inconstant findings and then only in the early periods of the disease.

1. Graves, William W.: Med. Rec., New York, Aug. 24, 1912.

Uhlenhuth and Mulzer[2] seem to have been the first to succeed in growing spirochetes in the testicles of rabbits from the blood and blood-serum of syphilitics during the primary and secondary periods of the disease and in one case[3] from the blood of a syphilitic mother four years after infection who had recently given birth to a syphilitic infant. Aumann[4] confirmed their results by using blood and blood-serum from the secondary periods of the disease. Nichols and Hough[5] have succeeded recently in growing spirochetes in the testicles of a rabbit from the spinal fluid in a case of relapsing cerebrospinal lues nine months after infection.

Each of these authors emphasized his failure to find spirochetes with the dark field in the material used for inoculations. No one, so far as I know, has as yet recorded successful inoculations of rabbits' testicles or otherwise cultivated the *Spirochaeta pallida* from the blood or spinal fluid of so-called latent syphilitics, paretics and tabetics. Yet work in this direction seems most promising since Noguchi and Moore[6] have recently demonstrated typical spirochetes in a number of brains of paretics. It is the purpose of this communication to give a brief account of an attempt to cultivate and otherwise recognize the virus of syphilis mainly in periods remote from the time of infection and particularly in paretics and tabetics.

My work in this direction began a little more than three years ago with the blood and spinal fluid and now embraces approximately five hundred cases, the majority of which were found in my service at the Alexian Brothers' Hospital. These cases were studied clinically from every angle and Nonne's four reactions were used in practically all of them in arriving at diagnoses. Most of the bloods were collected from forearm veins under sterile precautions while a few were collected in ampules from ear lobules. The spinal fluids were invariably collected in a sterile manner. Bloods and spinal fluids were contrifugalized soon after withdrawal. Blood-serum from corpuscle and serum junction in test tubes or ampules and the centrifugate of spinal fluids were studied in smears stained in various ways, in native preparations, and with so-called vital stains; with India ink and with adequate dark field illumination. In only one case, that of lues spinalis, ten years after infection, were spirochetes found in the spinal fluid with the aid of the dark field or otherwise and in only two cases in the blood and in these during the eruptive stage of the disease.

My observations on the bloods and spinal fluids of syphilitics are wholly in accord with those of many others in showing that the spirochetes can rarely be demonstrated in the blood and spinal fluid. It would seem that until we can acquire more exact knowledge of the morphology of the *Spirochaeta pallida* and are, perhaps, thereby able definitely to recognize the granule forms mentioned by Noguchi,[7] or as it may be an encysted form analogous to that described by Perrin[8] in connection with the *Spirochaeta balbianii*, or the spore stage assumed to exist by many authors, attempts to demonstrate "specific" spirochetes in the blood and spinal fluid with any degree of constancy seem to be hopeless undertakings.

The almost universal negative results in demonstrating spirochetes in blood and spinal fluid derived from syphilitics caused me early in my studies to accept the idea held by many of a cycle of development in which a spore-like stage existed. As early as October, 1910, I found quite constantly in the spinal fluids of syphilitics and seemingly paralleling in number the intensity of the disease processes, non-motile round bodies and actively motile granules. The granules vary in size from ¼ to 1 micron. The smaller granules resemble the smaller so-called hemaconia, have a low refractive index to the dark field, are not centrifugalizable at moderate speeds and are not stained by ordinary dyes. The larger granules have a relatively high refractive index to the dark field, are centrifugalizable at moderate speeds and are readily stained by basic dyes.

I was at the time and still am unable to find those granules mentioned in the literature as occurring in spinal fluid. They are readily differentiated from fragments of cells found in normal and pathologic spinal fluid. I mention them here merely to caution others against interpreting them as "spores" of the *Spirochaeta pallida*. Continued studies soon showed that similar-appearing granules were found in the blood, in ascitic fluid, in transudates generally, in the bodily secretions such as saliva, tears, bile and urine, not only in syphilitics, but in non-syphilitics and likewise in the blood, spinal and other body fluids and secretions of dogs, rabbits and monkeys.

It finally occurred to me that if the syphilitic virus does remain viable in blood and spinal fluid despite the resistances of the body, then some impetus to its development might be secured by culturing *in vitro* the bloods and spinal fluids of syphilitics. Studies of approximately two hundred bloods and spinal fluids cultured in hermetically sealed ampules failed to yield the *Spirochaeta pallida* in a single instance, though the blood from ear-lobules constantly yielded other micro-organisms, the most frequent being the *Staphylococcus albus*. Moreover, the contaminated bloods as well as those remaining sterile disclosed many forms described by von Niessen[9] as stages in the development of his "syphilis bacillus"; the "*Cytorrhyctes luis*" of Siegel;[10] bodies recently described by W. Ford Robertson[11] as stages in development of his so-called *Bacillus paralyticans* and bodies recently described by McDonagh[12] as forms in the life-cycle of the virus of syphilis. My studies of sterile and contaminated bloods from syphilitics, from non-syphilitics and also from dogs, rabbits, cats and monkeys compel me to say that normal products in the blood, or artefacts, or contamination, one or more or all combined, will account for most of the findings in the blood assumed by the authors just mentioned to be either the virus of syphilis or stages in its morphology.

Perhaps the most confusing forms found by me in the bloods of syphilitics and later in non-syphilitics and animals were those which were similar to those described by Krystalowicz and Siedliecki[13] in 1908 as contracted, ring and condensation forms of spirochetes. Indeed, their *Forms 12 and 20,* and 25 to 47, inclusive, here reproduced in Figure 1, may be readily shown in mammalian blood generally. It can be shown with alkalinized stains, the dark field, with moist India-ink preparations, fresh mounts and vital stains in one way or other that the forms just referred to, as well as several others which I have encountered and at one time considered as phases in the morphology of spirochetes, are either artefacts or normal constituents and these, together with the non-motile round bodies and the granules already mentioned, will be made the subject of an early communication.

With the announcement of Noguchi[14] in August, 1911, of a method of pure cultivation of *Spirochaeta pallida,* two additional avenues of research bearing on the problem in hand were made possible; first, the morphology of the virus might now be studied in pure cultures free from other biologic products than those in the medium and free from artefacts; second, the medium might prove suitable for the cultivation of the virus directly from blood and spinal fluid of syphilitics.

I have made use of both means and in the beginning largely through the kindness of Dr. Noguchi. In August, 1912, he gave me his C 2 and McD. *pallida* strains and during August and September, 1912, provided me with an abundance of ascitic fluid agar tissue medium, during which months, through the courtesy of Dr. Ewing, I enjoyed the privileges of the pathologic laboratory in the Cornell Medical School. It is a pleas- at this place to gratefully acknowledge my indebtness to Dr. Hideyo Noguchi for his generosity in supplying me with pure cultures and perfect mediums and to Dr. Ewing for the facilities of a splendidly equipped laboratory.

Both the Noguchi strains have been repeatedly transplanted and studied and no change has been noted in their morphology. The morphology of these strains, as well as of two impure strains which I have succeeded in cultivating in Noguchi mediums, seems to be constant and relatively simple. I have been able to make out with the aid of stains and the dark field but two definite stages in development; namely, the spirochete itself with curves varying from one to thirty or more and spore-like round bodies which were described by Noguchi[14] in his first paper on the pallidum. In referring to his Figures 46, 47 and 48, Noguchi speaks of these spore-like bodies as follows:

> Sometimes several round bodies are seen in a group and these are entangled in a mass of short irregular forms of *pallida.* It is not rare to find a round body connected with one or two young *pallida* as though the latter were just sprouting from the former. The *pallida* with these round bodies are motile. The size of this spore-like round body is variable. They are difficult to stain but when stained they take chromatin stain.

My observations are in accord with those of Noguchi concerning the form of these spore-like round bodies, their variable size, the sprouts which seem to come from them and their resistance to stains. Only in the best Giemsa preparations may they be seen at all. They are best stained by Stern's silver method. Drawings from a preparation derived from a thirty-eight day old subculture of Noguchi's McD. strain and stained by this method are reproduced in Figure 2. Well-stained Levaditi preparations show them constantly and some in great numbers.

Each of these bodies, as a rule, is spherical, having a uniform rim-like stainable periphery, while its interior seems void and unstainable. The bodies vary in size from ½ to 2 microns. In some cultures they seem to be more numerous than the spirochetes. In others, the converse is true. They are more often connected with spirochetes having few curves. When not sprouting these spore-like bodies are motionless, a point in analogy with spores in general; but in those specimens having one or more sprouts, motility may be made out and this seems to increase with the number of curves. One or more of these bodies are often in juxtaposition, but I have never seen a line of fission.

Noguchi[7] has noted in old cultures the breaking up of spirochetes into granules and I have noted the same in his and in my own cultures. May it not be that these granules subsequently develop into spore-like round bodies? If this be true, then the cycle in development would be: granule—spore-like body; spirochete—granule. Until we learn more about Noguchi's granular forms and the spore-like round bodies and by special stains or other means are enabled definitely to recognize and differentiate them from all other forms, the microscopic recognition of the virus in these and it may be in other forms remains a hopeful problem of the future.

While my attempts to recognize the virus in fresh and cultivated blood from syphilitics in the later periods of the disease have remained negative, I have seemingly been more fortunate in my experiments with Noguchi mediums and with rabbits. With the aid of ascitic fluid agar tissue mediums (Noguchi) I have succeeded in cultivating spirochetes from the blood of two chronic syphilitics, and from the blood of two paretics I have gotten a growth in rabbits.

Experiments with Noguchi mediums were begun in February, 1912, resumed in August, and have been continued up to the present time. The total number of cases from which either blood or spinal fluid or both have been cultured in the ascitic fluid agar tissue medium is 130. Of this number, 40 were paretics; 20, tabetics; 12, lues cerebri; 8, lues cerebrospinalis; 12, lues spinalis; 20, so-called latent syphilitics; 3, primary; 8, secondary; 4, tertiary; and 3, congenital syphilitics. The quantity of blood or spinal fluid from each case added to the mediums and incubated at 37 C. (98.6 F.) varied from 0.5 to 2 c.c., and these quantities were passed well down to the tissue with a fine pipet. In a few cases diffuse cultures were made by the addition of syphilitics' blood or spinal fluid in quantities equal to the percentage of ascitic fluid used in Noguchi mediums, and in these cultures no ascitic fluid was employed, the idea underlying this procedure being that greater quantities of the assumed virus might thus be cultured.

A few of the number of bloods and spinal fluids were immediately inoculated into Noguchi mediums, while most of them were incubated from three to ninety days either in hermetically sealed ampules or in test-tubes, and when in the latter, paraffin oil was added to prevent evaporation. It seemed likely that some impetus to development of the assumed virus might be secured by thus incubating the bloods and spinal fluids before adding them to Noguchi mediums. Be this as it may, it is, nevertheless, true that the first culture secured with Noguchi mediums was derived from blood thus incubated. The blood was collected in three ampules

[14] Noguchi, H.: Jour. Exper. Med., xiv, No. 2.

(approximately 1 c.c. in each) Nov. 28, 1911, from a normal appearing ear-lobule of a male syphilitic thirty years after "specific" infection. The patient had been admitted to my service at the Alexian Brothers' Hospital, Nov. 26, 1911, complaining of weakness in legs and sphincter weakness. He was greatly emaciated and cachectic, showed definite physical signs of lues spinalis and Nonne's four reactions were present. He died three days after admission, within twelve hours following an intravenous injection of salvarsan. Necropsy was not permitted. The sealed ampules were incubated at 37 C. (98.6 F.) until Feb. 9, 1912, and on this date the contents of one ampule was inoculated into a Noguchi medium tube supplied by Dr. Gradwohl, labeled 2 B, and the other ampules were thereafter kept at room temperature.

On Aug. 24, 1912, the contents of a second ampule was inoculated into mediums supplied by Dr. Noguchi and labeled 2 B X, and that of a third ampule was inoculated Nov. 8, 1912, into Noguchi mediums which had been prepared under my supervision, this tube being labeled 2 B X 1. Each of these cultures showed contamination mainly by *Bacillus subtilis,* and each of them many spirochetes, all having the identical morphology, yet differing from the typical morphology of Noguchi's *pallida* strains. The differences thus far noted are (*a*) decided rigidity; (*b*) feeble movement; (*c*) marked regularity in the curves and being slightly wider in the middle; (*d*) extreme resistance to strains.

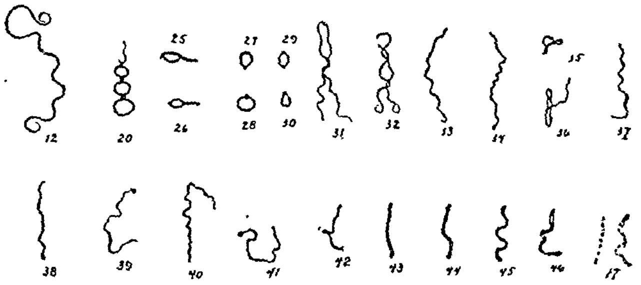

Fig. 1.—Confusing forms found in blood of syphilitics, nonsyphilitics and animals; forms that may be shown in mammalian blood generally.

Cultures 2 B, 2 B X and 2 B X 1 have been repeatedly subcultured without change in morphology and despite every effort at purification the *Bacillus subtilis* remains. The spirochetes in these cultures seem, like Noguchi's *pallida,* to originate from spore-like round bodies, and they have even a greater resistance to stains. The peculiar morphology may be accounted for, possibly, by differences in *pallida* species, or by altered cultural conditions incident to the presence of the bacillus subtilis, or by considering them of a species not hitherto described, or by considering them involuted forms analogous to those noted by Noguchi[15] while cultivating his *macrodentium* strains. Until purification can be accomplished or strains having similar morphology can be secured direct from syphilitic blood drawn under sterile precautions, identification cannot be definitely determined.

The points of special interest in connection with strains 2 B, 2 B X and 2 B X 1 are that the virus was derived from the blood of a syphilitic thirty years after infection and that it remained viable in sealed ampules for 71, 266 and 310 days, respectively, after drawing the blood and before adding it to Noguchi mediums.

The blood from which the second growth in Noguchi mediums was secured was drawn June 12, 1911, in an ampule from the ear-lobule of a syphilitic twenty-three years after infection. The patient had optic atrophy and diplegia following an attack of lues cerebrospinalis eight years before coming under observation. The blood of this patient was kept at room temperature and inoculated into Noguchi mediums Aug. 29, 1912, one year, two months and twenty-eight days after sealing it in an ampule. This culture was not examined until March 4, 1913, and a few typical spirochetes were found. Several subcultures were immediately made, but thus far no growth has occurred in any of them and the original culture no longer shows spirochetes. In this culture the growth was evidently feeble, but that growth should have occurred at all seems noteworthy, particularly when it is remembered that the blood from which it was derived was kept in a sealed ampule at room temperature for more than a year.

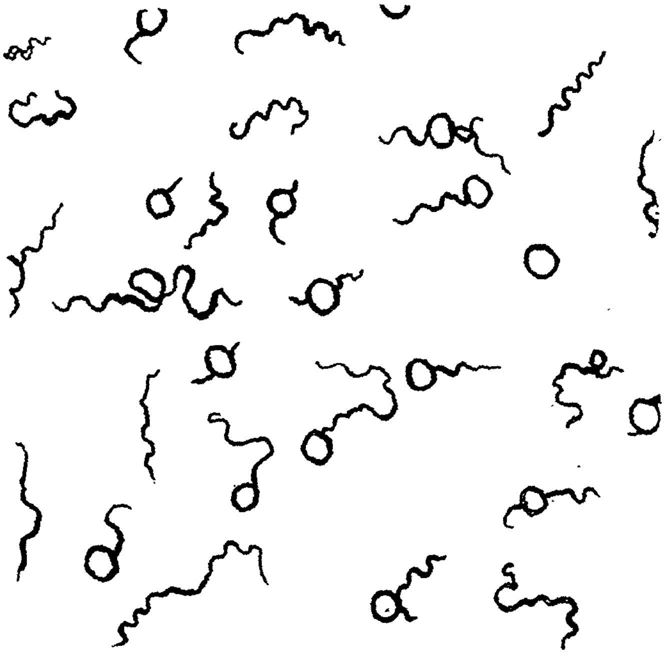

Fig. 2.—Drawings from a silver preparation of Dr. Noguchi's McD. strain illustrating spore-like round bodies and their relations with spirochetes.

Assuming the strain from the case just cited and strains 2 B, 2 B X and 2 B X 1 to be *pallida,* it would seem that the cultivation of the syphilitic virus directly from the blood of chronic syphilitics with the aid of Noguchi mediums is among the possibilities of the laboratory. Even though the blood from only two cases out of one hundred and thirty yielded positive results, they are, nevertheless, encouraging and should stimulate us to learn, if possible, the conditions most favorable for the successful cultivation of the virus *in vitro* when derived directly from the blood or spinal fluid of syphilitics.

Thus far blood from four classical cases of general paresis and from one case of taboparesis has been injected in quantities of 2 c.c. in each testicle of healthy full-grown rabbits. Only one rabbit has been used in each case. The rabbits were free from skin lesions and studies with the dark field showed no spirochetes in the buccal cavities, about the genitals or anus. The bloods were collected in a sterile manner from forearm veins and no visible lesions of the skin were noted in any case. The bloods were neither defibrinated nor was citrate or oxalate of sodium employed to prevent clotting. In four of the five cases bloods were incubated from two to seven days at 37 C.; whereas in one case it was injected two hours after drawing it. Before injecting the blood it was mortared and the clot thus partly broken yielded a rich red serum. In injecting the blood the needle was caused to penetrate the long axis of the testicle, the point of the needle passing twice through the tunics, and as the needle was withdrawn the blood was distributed first between the tunics and, secondly, along the course of the needle. I shall give abstracts of histories and rabbit protocols only in the two cases yielding positive results.

---

[15] Noguchi, H.: Jour. Exper. Med., xv, No. 1, 1912.

REPORTS OF CASES

Case 1.—Man, married, aged 37, had sustained a luetic infection eighteen years ago, receiving thereafter two years' continuous treatment. He became a prominent business man and is said to have been in good health until four years ago, when shooting pains developed in the legs, though transient diplopia occurred on several occasions during the last eight years. For the past two years slight unsteadiness in the dark had been noted. Slight change in disposition was noted in the summer of 1911 and in October of the same year a rapid onset of mental symptoms pointing to general paresis developed. He was seen at that time by Drs. Fry, Hoge, Bliss, Herman, Campbell and myself. His mental state was one of disorientation, confusion and expansion.

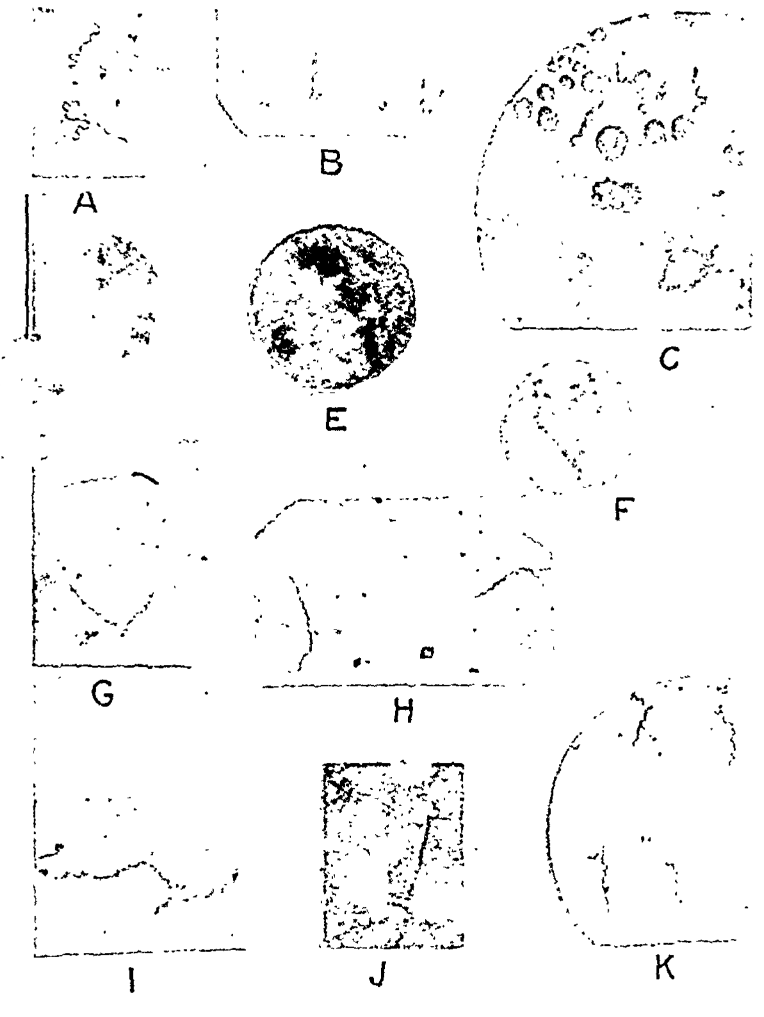

Fig. 3.—*Spirochaetae pallidae: a, b, c, f, g, h, i,* and *k* are from Giemsa preparations from tissue emulsions of lesions of Rabbits 4 and 15. Note the spore-like round bodies in *a, b* and *k*. The others *(d, e and j)* are spirochetes from strains 2 B, 2 B X and 2 B X 1 from dark field photomicrographs. Magnification in *i* is approximately 1,000; in other figures 800.

The physical examination disclosed associated tremor of facial muscles, syllable stumbling, entire absence of lower and upper extremity, tendon and periosteal reflexes, Gordon toe reflex on right, absent abdominals and marked analgesia, especially over legs, slight Rombergism, slight ataxia of lower extremities, well-reacting pupils and normal eyegrounds. The clinical diagnosis at the time was taboparesis. The laboratory findings secured within two weeks after onset were Wassermann reaction in blood-serum and spinal fluid positive, 120 lymphocytes per cubic millimeter and increased globulin content in spinal fluid.

Three months after onset a definite remission occurred lasting several months, during which time the patient seemed quite normal mentally. In July, 1912, right-sided epileptiform convulsions occurred, followed by temporary aphasia and weakness. Following this numerous similar attacks with increased deterioration marked the progress of the disease, death occurring in a convulsive seizure in March, 1913. This patient was under active mercurialization from November, 1911, up to within a short time before his death and in July, 1912, he received 0.6 gm. of salvarsan intravenously.

Blood from this patient for Wassermann reaction and rabbit experiment was drawn Jan. 25, 1913. The Wassermann reaction at this time was negative. The blood was incubated at 37 C. (98.6 F.) until February 1 (seven days), when 2 c.c. were injected into each testicle of a full-grown black rabbit, No. 4.

Case 2.—Man, aged 41, had an initial lesion fourteen years ago and thereafter two years' continuous treatment. He was admitted to Alexian Brothers' Hospital Feb. 3, 1913. Mental change first noted four months ago. On admission marked disorientation for time and place, no insight, expansive delusions, marked excitement, Argyll Robertson pupils, facial tremor, syllable stumbling, unequal and exaggerated tendon reflexes, a pathologic toe reflex on the right. Nonne's four reactions present.

On February 22 blood drawn from forearm vein and two hours later 2 c.c. of this were injected into each testicle of a healthy white rabbit, No. 15.

The positive results thus far secured with inoculations of blood from the two cases of general paresis into the testicles of Rabbits 4 and 15 may be thus summarized: After sixty-six days' incubation Rabbit 4 showed spirochetes in right testicle and in tissue emulsions from lesions about eyelids, perineum and anus, the skin lesions persisting approximately forty days. The skin lesions recurred about the anus and eyelids seven and twenty-three days, respectively, after their complete disappearance. Specific testicular lesions have been produced in two rabbits by inoculating tissue from lesions from Rabbit 4. After approximately forty-eight days' incubation Rabbit 15 showed spirochetes in lesion about the prepuce, persisting approximately forty-five days, and during the activity of this lesion the disease was transmitted to two female rabbits by mating, to the one with, to the other without scarification of vaginal orifice; to one rabbit by inoculation of scarified surface of upper lid and to one rabbit by injecting tissue emulsion from prepuce lesion into testicles. A lesion recurred about prepuce in Rabbit 15 seven days after all lesions had completely disappeared. Lesions also recurred in Rabbits F 15 A and F 15 B after their complete disappearance. Gummas were found in right testicle of Rabbit 15 after an incubation period of ninety days. The spirochetes from the lesions in each of the infected rabbits show to dark ground illumination, to Giemsa stain and to India ink a morphology identical with that of *Spirochaeta pallida*.

On June 1 tissue emulsion from anal lesion of Rabbit 4 and stained preparations from tissue emulsions from Rabbits 4, 15, F 15 A and F 15 C were sent to Dr. Hideyo Noguchi for study and criticism, and in a letter dated June 7 he states: "I found typical *pallida* both in the emulsion and in stained preparations."

CONCLUSIONS

On the evidence recorded in this paper it seems we are justified in affirming that rabbits can be infected with the virus of syphilis directly from the bloods of general paretics. Until confirmatory and additional work can be done, clinical observations and laboratory methods will continue to support the idea that in paretics, tabetics and so-called latent syphilitics the living virus of syphilis is ever present.

Metropolitan Building.

ABSTRACT OF DISCUSSION

Dr. Charles R. Ball, St. Paul: Dr. Graves' paper presents positive and definite results which must be seriously reckoned with in any consideration of the nature and cause of general paresis.

Dr. Sanger Brown, Chicago: I suppose it is too early to draw any hard and fast conclusions, but it is certainly very gratifying to know that work tending toward definite demonstration is being done, and I think that it might lead us to hope that we will finally discover the causation of general paresis. There are, of course, many things to be cleared up. A great deal of work must be done by different investigators, and they must compare and check up their results and methods closely. For instance, it appears conclusively from Dr. Graves' paper that the specific virus, after remaining in the human subject for twenty-five or thirty years, can infect a rabbit with the positive lesions of syphilis; and yet it is pretty well established, no matter what laboratory experiments might seem to show, that usually after two or three years nothing remains in the human subject which can be transmitted to produce the acute diseases in the human female. These are questions that will have to be cleared up. The main and important element in this work is that it is apparently leading up to the causation of syphilis, and we hope that something may develop from it to enable us to cure or prevent the disease.

Dr. William W. Graves, St. Louis: I hope that I have not made the impression that I feel that my report to-day is in any sense final. The work must, of course, be confirmed by others and must be done on a much larger scale than I have been able thus far to carry out.

I think that the actual demonstration of the virus would convince some people of the real effects of syphilis, not only so far as it affects the individual himself, but also so far as it affects his wife and family. From my own observations I have long since come to the conclusion that the syphilitic, however thoroughly we have cured him, is still a menace to himself and to his family.

In answer to Dr. Brown I may cite this experience, which those who have had opportunity of curing syphilis as I did during the early years of my professional career may verify if they will. Out of twenty cases of syphilis which I had treated no less than two, three, four or five years, as we treated syphilis twenty-five years ago, eight of the wives of the syphilitics gave positive Wassermann reaction, and very few failed to show some physical signs that could be attributed to a syphilitic infection. Out of all of the children of these patients, about seventy, I did not find one that compared favorably with either parent. I therefore believe that the idea suggested by Dr. Brown, that the syphilitic is a harmless member of society after he is cured, is not tenable. If we will observe our patients over a number of years after infection, we shall find that they show ever-increasing signs, particularly in connection with the cardiovascular apparatus and the nervous system, which can be attributed only to a former syphilitic infection. We need to diagnose this condition through a laboratory method. In the diagnosis of the cases we have, of course, the Wassermann reaction, which is of the greatest help, and we need to recognize definitely the virus of syphilis in the various periods of the disease as readily as we now recognize the tubercle bacillus in tuberculosis. I believe that this will be the ultimate outcome of laboratory research.

CULTIVATION OF THE RABIES ORGANISM *

ANNA WESSELS WILLIAMS, M.D.
NEW YORK

From the earliest days of artificial cultivation many investigators have attempted to grow the specific organism of rabies, but few have had the courage to report positive results. Among the latter may be mentioned, for example, Bruschetti (1896), who reported that he had cultivated on special brain-broth mediums an extremely minute pleomorphic bacillus, which up to the sixth culture generation produced typical rabies in susceptible animals; and later Levy (1903), Sormani (1903) and a few others reported equally positive results with cultures of different micro-organisms isolated from rabies animals. No one so far has been able to corroborate these results.

Since Negri and others demonstrated that the structured cell inclusions known commonly as Negri bodies are specific for rabies, there have been practically no cultural studies reported; but from verbal reports and demonstrations we know that such studies have been going on in several research laboratories.

Among those most interested in the subject is the research laboratory of the New York City Department of Health, which has been more or less actively engaged in investigations concerning the etiology of rabies since 1897, when practical studies on the treatment of this disease were begun there.

As a culmination of a series of studies on the etiologic side of this question I published several reports[1] in 1904 and 1906 dealing chiefly with the nature of the Negri bodies, in which it was shown that the evidence presented was strongly in favor of a specific protozoal cycle of development in these bodies. I therefore, wisely or unwisely, gave them a generic and specific name, *Neurorrhyctes hydrophobiae*. The chief points, first brought out in these papers, which led to this conclusion may here be briefly recapitulated:

1. By a new method for the examination of rabies brains (the smear method) Negri bodies show distinct characteristics in both morphology and stain.
2. Their morphology is constantly cyclic, that is, a definite series of forms indicating growth and multiplication can be demonstrated: small, single, rounded or oval plastin-staining forms containing from one to several minute chromatin-staining granules; similar forms in twos or groups; larger forms containing a definite central or eccentric chromatin mass (nucleus); forms with smaller chromatin masses arranged in a ring about the central mass; evidence of division of these larger forms as well as of the smaller ones; segmentation of chromatin and distribution of nuclear-staining material throughout the whole organism; division of the organism into many minute bodies, and finally, from the beginning of the appearances of the smaller masses of chromatin, all stages of budding, a phenomenon which accounts for the appearance in the same cell and at the same time of both large and small forms, and also helps to account for the rapid spread of the organism and for forms small enough to pass certain filters.
3. In rabbit "fixed virus," besides the few larger forms seen by others, very many extremely minute forms are found, within most of which are seen in well-fixed and stained preparations a single chromatin granule.
4. With stains such as Giemsa's the lightly basophilic property of the "cytoplasm" of the bodies and the chromatin-like

Soc., 1904, iv, 107; Negri Bodies with Special Reference to Diagnosis, ibid, 1906, v, 155; Studies in Hydrophobia, *ibid.*, 1906, vi, 77. Williams, Anna Wessels, and Lowden, May Murray: The Etiology and Diagnosis of Hydrophobia, Jour. Infect. Dis., 1906, iii, 452.

nature of the contained masses and granules are brought out in smears better than in sections.

5. Negri bodies are found in all parts of the infectious central nervous system, beginning to appear in the large nerve cells as extremely minute forms before the beginning of symptoms; *that is*, on the fourth day in fixed virus infections and on the seventh day in rabbits inoculated with street virus; thus they were found early enough to account for the infectivity of the host tissue.

Most of these findings were confirmed by a few investigators immediately following their publication. Recently Watson[2] added his corroboration and states that he found in addition spore-like bodies similar to myxosporidian spores.

No one has yet brought forward clear evidence against these findings of a definite cycle of development.

Recently there appeared Dr. Noguchi's announcement on the cultivation of the parasite of rabies.[3] This announcement unfortunately leaves us with no more exact knowledge of the cultivation of the rabies organism than we had before.

Naturally, with the idea of the protozoal nature of the Negri bodies in mind, I have made attempts to grow them in artificial culture mediums supposed to be suitable for pathogenic protozoa, but results so far have been either too unsatisfactory or too unfinished for publication. Others have tried newer culture methods also with negative results. Thus Poor and Steinhardt[4] state that they are unable to obtain evidence of growth by the living tissue method of culturation. A few suggestive ideas, however, have been obtained from some of the observations made during my studies, which, in order to discuss Noguchi's report, may be published now.

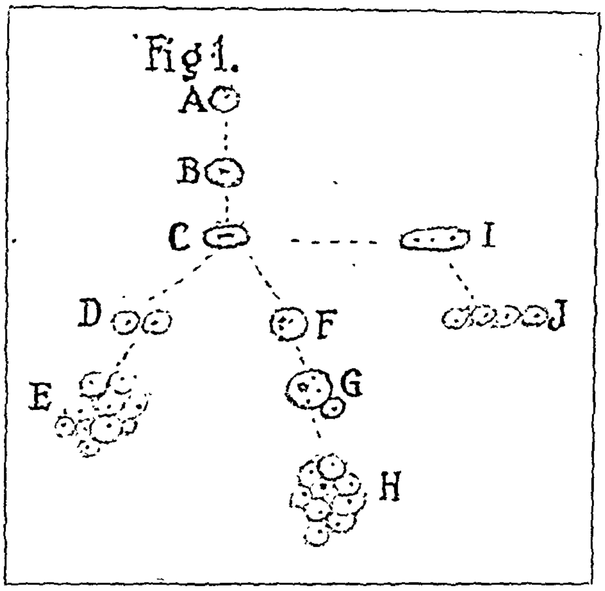

Fig. 1.—From rabbit "fixed-virus" brain; *a, b, c, d, f* and *i*, types of Negri bodies seen at death of rabbit; *c, g, h* and *j*, apparent multiplication and segmentation of the bodies after three days at 24 C. *All drawings in this illustration and Figure 2 made from smears stained by Giemsa's method and magnified about 2,000 diameters.*

In the first place, it may be stated that no change of mind has been necessary concerning the varieties and arrangements of the Negri bodies as shown in my plates published in 1906. Such forms are still called "typical Negri bodies."

The observations may be divided into two groups: (I) changes in rabid brains after death of animal and (II) passage of virus from culture to culture.

I. CHANGES IN RABID BRAINS AFTER DEATH OF ANIMAL

When brains containing "typical Negri bodies" are kept, free from contamination, either at ice-box (12 C., 53.6 F.), room (24 C., 75.2 F.) or incubator (36 C., 96.8 F.) temperature certain changes occur, more slowly at the lower temperatures.

First, in rabbit "fixed virus" brains which on removal from an animal dying or dead from rabies usually show only the minute forms (Fig. 1, *a-d*), in about twenty-four hours at 36 C., forty-eight hours at 24 C. and three days at 12 C., some of the larger forms appear (Fig. 1, *f, g, d*) and more definite groups of smaller forms (Fig. 1, *c, h, j*). Some of the groups seem to be surrounded by a sort of membrane taking a *mixed chromatin and* plastin stain, and others seem to be free. These segmented bodies *remain longer* at the lower *temperatures and disappear when the brain becomes much softened.*

Secondly, in "street" and "passage" virus brains, many of the large forms appear to become *distinctly separated into smaller forms, some within a "membrane" and some* in free groups (Fig. 2, *a, h*).

These changes are seen more clearly in brains left in the skull of the animal or in brains excluded from the air by some method such as pouring agar or serum over them. Animals sent in for diagnosis, which have been buried for some time during cool weather, may show these changes quite distinctly.

By animal inoculations with dilutions, material with these segmental-like forms seems to have gained somewhat in virulence. Whether it is a real gain by an actual increase in the number of organisms, or whether higher dilutions are more virulent simply through the breaking up of groups of organisms, thus allowing more even distribution throughout the diluent, has not been decided.

II PASSAGE OF VIRUS FROM CULTURE TO CULTURE

The last cultural method tried is a modification of the tissue-medium method employed by me[5] in obtaining pure cultures of amebas from amebic dysentery.

A thin slice of fresh sterile guinea-pig's brain was placed on freshly made protozoan-agar (Musgrave and Clegg, 1904) plates over a piece of rabbit "fixed-virus" brain the size of a pea. Over this mass was then placed *a thick layer of protozoan agar.* This was kept at about 25 C. (77 F.).

Transplants were made at the end of seven days by removing the agar, stirring up the mass, transferring about one-fourth *of it to a fresh* agar plate and covering *with fresh* brain tissue *and* agar as before. After each transplant some of the brain mass (about the size of a pea) was made into an emulsion with 5 c.c. normal salt solution, and two drops of this emulsion were inoculated intracerebrally into guinea-pigs. The pigs came down with typical rabies after the inoculation of the fourth culture generation in all of the three series so far tried. By the fifth transplant in these series *the material* was contaminated, and the inoculated animals did not come down with rabies. The question of dilution of the virus was of course considered, but here again the controls *have not* yet been sufficient to make *sure that* some growth, however *slight, did* not take place.

4. Poor, D. E., and Steinhardt, Edna: Two Methods for Obtaining a Virus of Rabies, Freed from the Cells of the Host and from Contaminating Organisms, and Application of *These* Methods to Other Filterable Viruses or Glycerin-Extracts, Jour. Infect. Dis., 1913, xii, 202; abstr., The Journal A. M. A., April 5, 1913, p. 1106.

5. Williams, Anna Wessels: Pure Cultures of Amebas from Intestines of Mammals, Jour. Med. Research, *1911*, xx, 263.

The larger apparently broken-up Negri bodies (Fig. 1, *c-j*) could not be found except in cases in which the possibility of having a piece of the original brain material in the smear could not be ruled out.

Of course in each brain mass "pleomorphic chromatoid granules" arose, but so did they in the controls, and no difference could be determined between them except that they were somewhat fewer in the controls.

Noguchi says that in culture mediums similar to that employed for the cultivation of the spirochetes of relapsing fever (are we to infer from this that it was the method he found best for these spirochetes, or one of the others, or all?) "very minute granular and somewhat coarser pleomorphic chromatoid bodies arise which on subsequent transplantation reappear in the new cultures through many generations."

Here is nothing definitely new. From Pasteur down, nearly all investigators on this subject have stated at one time or another that minute and coarse granular pleomorphic bodies are the cause of rabies, and any observer may see granular bodies answering to Noguchi's description, arising in uninoculated tissue mediums after the tissue has undergone a certain amount of degenerative change.

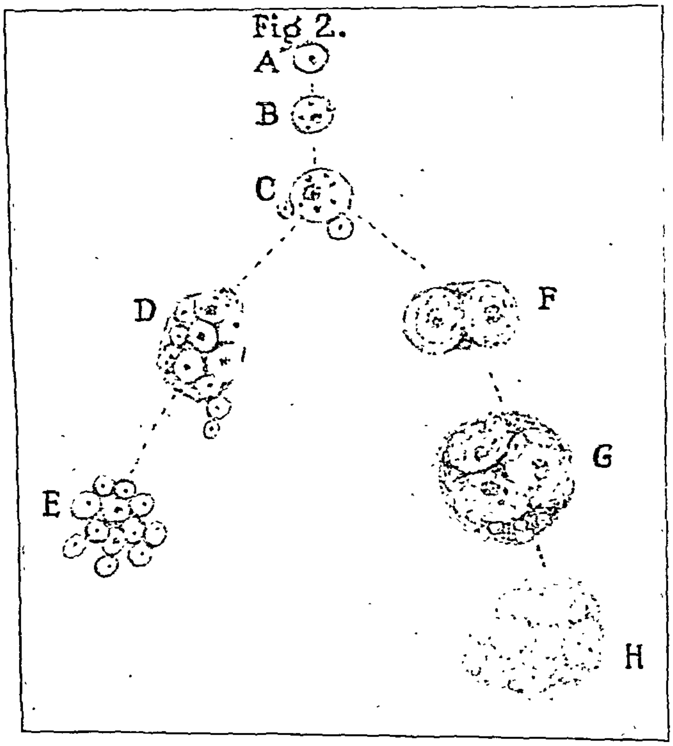

Fig. 2.—From dog "street-virus" brain; *a*, *b*, *c* and *f*. types of Negri bodies seen at death of dog; *d*, *e*, *g* and *h*, apparent multiplication and segmentation of the bodies after three days at 24 C.

Noguchi continues: "On four different occasions I observed in the cultures from "passage" and "fixed" virus nucleated round or oval bodies surrounded with membranes totally different from the minute granular bodies, although arising in the cultures in which the latter occurred."

Is it certain that these bodies are not merely segmented bodies which are carried over from the original material? We cannot be sure, since no mention is made of culture generations in Noguchi's article, except in the description of the illustration, in which the only note is that two of the observations were made on "a culture (second and fourth generations, five days old)."

In regard to the specific virulence of his "cultures" Noguchi says, "By inoculating cultures containing the granular, pleomorphic or nucleated bodies, rabies has been produced in dogs, rabbits and guinea-pigs."

Here again the culture generation is not stated. Furthermore, as nothing is said about the amount of material transferred, or about the number of days before the transfer is made or about control dilutions in testing virulence, the question may be raised as to whether the positive results asserted were not due to dilution of the original material rather than to continued growth and division of a specific organism. It is hoped that later reports, by making clear these details, will help decide this question.

A CLINICAL REPORT OF SEVEN CASES OF HYDROPHOBIA

TOGETHER WITH A CASE CLINICALLY SIMILAR, WITH RECOVERY FOLLOWING THE INJECTION OF QUININ *

D. L. HARRIS, M.D.
ST. LOUIS

The following seven cases of hydrophobia (Cases 1-7) are reported because of the persistent assertions of so many misinformed persons that no such disease exists, and because of the strenuous opposition which these make against any plans looking toward the elimination of the dog nuisance. Unfortunately, this opposition has the support of a few members of the medical profession and of several widely circulated newspapers. The efforts of the Health Department of St. Louis to lessen the danger of rabies by the capture of stray dogs and the temporary muzzling of owned dogs have been greatly hindered by the editorial opposition of two of the local papers. It is hoped that the brief clinical review of the seven deaths here recorded may in a measure add strength to the documentary and experimental evidence of the existence of hydrophobia, and give pause to those opponents who desire light.

I have also added to these cases the record of a patient (Case 8) whose clinical symptoms were strikingly similar to the others, and whose recovery followed the intravenous injections of quinin and urea hydrochlorid. Although in the latter case biologic proof of the existence of rabies is wanting, I am disposed to regard the diagnosis of hydrophobia as correct and attribute recovery to the drug employed.

REPORT OF SEVEN FATAL CASES

CASE 1.—W. U., aged 12, was bitten, May 18, 1911, by a rabid dog. The injury consisted of two deep punctured wounds on the forehead, one of these just over the supra-orbital notch, 1 cm. long. The wounds were cauterized within an hour with a stick of silver nitrate. Antirabic treatment (Pasteur) was begun on the following day and continued for fifteen days.

On June 18, the twelfth day after the last injection, the twenty-eighth day following the injury, the boy was nauseated and vomited several times. The following day he attended school but felt ill all day and complained of a severe headache. In the evening his physician was called and found him very restless and in great mental distress. He slept but little that night and symptoms steadily increased. Forty-eight hours after the onset he was unable to remain in bed. He ran excitedly around the house, screaming, moaning, groaning and beating his hands against the wall and furniture.

Short periods of comparative quiet alternated with others of pronounced manic restlessness. The saliva flowed freely, was tenacious and ropy, and smeared over his lips and chin. In the periods of relaxation he talked rationally and spoke of his approaching death.

---

* From the Municipal Laboratory of Pathology and Bacteriology, St. Louis.

On the third day his restlessness was uninterrupted, convulsions were frequent, he developed delusions and was mildly delirious until his strength gradually failed and he died seventy-two hours after the onset.

Though intensely thirsty, the patient was seized with spasmodic contracture of the pharynx at every effort to swallow. He suggested and tried various devices to drink. He would, for example, close his eyes to avoid the sight of the glass, or he would try to bring it to his mouth suddenly before a spasm would come on. But before he could complete the motion his arm would tremble violently and then stiffen, his pharyngeal muscles contract and his whole body would be held in a rigid spasmodic seizure.

During the twenty-four hours preceding his death he was given six hypodermic injections of morphin sulphate, ¼ grain each, and 80 grains of chloral hydrate by rectum. The only effect of those was to lessen the severity of the convulsive seizures, which came more and more frequently.

No Negri bodies were found in the brain, but rabbits were inoculated with the medulla and all of these died within three weeks. Negri bodies were abundant in all of these.

Case 2.—On Aug. 3, 1911, G. B., a well-nourished, well-developed Irishman, aged 51 years, walked into the laboratory, having been sent to me by his physician who had not intimated to him the nature of his trouble. On being questioned, the patient said that for two nights he had not slept, that he was nervous and worried, that he had a severe pain radiating down his left arm, and that for the past twenty-four hours he had some peculiar trouble in his throat whenever he tried to swallow. I asked him the cause of a small and insignificant scar on his little finger and he replied that some time during the latter part of April he was bitten by a stray bulldog that had attacked his cat. In driving the dog away it had bitten him on the finger. The wound was not cauterized. On further questioning he admitted a strong aversion to water, even to the thought of drinking it. He was quite convinced, however, that there was no relation between the insignificant dog bite and his present "nervousness."

The symptom of hydrophobia was acutely developed in this case. The suggestion of a bath on admission caused him to tremble from terror and fear. Some hours later the question of a physician, "Have you passed any water to-day?" was sufficient to start a general convulsion. In spite of this and the patient's clear mental grasp, he did not once associate his condition with the dog bite, nor did he recognize his disease as hydrophobia.

On admission to the City Hospital he rapidly became more restless and hypersensitive to noise, light and drafts of air. Convulsive movements became pronounced, notwithstanding repeated injections of morphin (5½ grains in twenty-four hours) and enemas of chloral hydrate. Twenty-four hours after admission he was seized with a prolonged and general convulsion, after which he rapidly weakened, followed by diaphragmatic paralysis and death August 4, thirty-four hours after admission, and eighty hours after the onset.

A necropsy was held, but the only gross pathologic lesion found was a congestion of the meninges. No Negri bodies were found in the brain, but two rabbits were inoculated with an emulsion of the medulla. These died within three weeks of dumb rabies, and in the brains of both Negri bodies were numerous.

Case 3.—Feb. 14, 1912, I was invited to be present at a coroner's necropsy on a woman who had died in convulsions. A physician, who had been called in a few hours before death, had pronounced the case one of hydrophobia. The following history was obtained:

A. W., a middle-aged woman, was bitten, Dec. 25, 1911, by a stray dog which her little daughter had found on the street and had brought into the house. After biting the woman, her husband and her daughter the dog was put out of the house and disappeared. The wound was not cauterized.

Five days before death the woman developed a marked pain and itching on her right leg. At the same time she became very excitable, extremely restless and could neither sleep nor remain quiet. A physician who saw her at that time reported that he regarded it as a case of hysteria and prescribed a mild sedative and a local treatment for the itching of the leg. He did not suspect hydrophobia. Her condition grew worse, she became delirious, fought, screamed and was restrained with great difficulty. Another physician was called and found that she could not swallow. Her death occurred a few hours later.

At the necropsy both legs were excoriated and covered with deep scratches. There was a small scar over the left ankle, with a pronounced cicatricial induration. The meninges were congested, otherwise there were no gross pathologic changes. Rabbits injected with an emulsion of the brain developed paralysis and died three weeks later. Their brains contained many Negri bodies.

Case 4.—H. M., a white man, aged 18, was admitted to the City Hospital, May 22, 1912, with the following history:

April 20, while urinating behind a large signboard, he was bitten on the glans penis by a stray dog. The wound was not cauterized. He at once began reading about the symptoms of hydrophobia, and when a week previous to his admission he began to be restless and nervous and to talk about having hydrophobia his family attributed his condition to worry and fear, and he was given bromids by the family physician. When he attempted to urinate he would have a seminal emission.

Immediately after his admission he was examined by two very competent neurologists. He was rational, but at frequent intervals there were convulsive movements, during which he would throw himself about the bed, seize his throat with both hands and complain that he could not breathe. After such attack he would expectorate large amounts of saliva. These seizures came on every two or three minutes, and a diagnosis of hysteria or pseudohydrophobia was made. He was given ¼ grain morphin sulphate and placed in a quiet, dark room. Four hours later he had a severe convulsion and died suddenly.

At the necropsy the only pathologic condition found was a greatly congested left lung, with large petechiae over the pleural surface. The brain was moderately congested. There was an old healed scar 3 mm. long on the glans penis. No Negri bodies could be found in smears of the cortex, the cornu ammonis or the cerebellum, and none could later be demonstrated in sections. Three rabbits were inoculated subdurally with the brain, and all developed paralysis during the third week. In all the rabbits Negri bodies were abundant in smears of the cornu ammonis.

Case 5.—June 14, 1913, H. C. H., a man, aged 80, walked into the laboratory and stated that he had come to have an examination made to determine whether or not he was developing hydrophobia. He said that three weeks before he had been bitten on the right wrist by a stray dog. The wound was slight — a single tooth-wound — healed promptly without cauterization and he had given the incident no further thought.

June 11 he did not feel so well as usual and there was or seemed to be a peculiar odor about water which made drinking very difficult. This dislike for water soon extended to milk, beer and all liquids, and later to solid food. He slept but little the night of the 11th and 12th and not at all on the night of the 13th. Partly because of his extreme thirst and partly from something which he could not explain, he became very nervous and irritable. "Choking-spells" developed on the 13th, especially when he lay down, so that he could rest only when sitting in a chair.

As he talked of his condition, his voice and manner indicated a slight excitement. When he lay down on the examining-table he had a spasmodic contraction of the throat muscles that momentarily suffocated him. The pulse was normal, of good quality and there was no apparent fever.

A glass of water placed before the patient produced a most striking excitement. He could look at it from a distance calmly, but could not, try as he might, bring himself to approach nearer. When, unexpectedly, the water was suddenly placed before him he recoiled in a paroxysm of fear, clutched his throat, and for a few moments breathed spasmodically and with great difficulty. He tried to drink milk, but, as he siezed the glass in his hand, he turned his face away and his arm trembled so violently that the contents were shaken to the floor. He had not the control of his muscles to bring the glass to his mouth.

He was advised to enter the hospital, which he did four hours later. On admission he was found to have a temperature of 103.4 and a pulse of 128. He was very irritable and excited and restless. Morphin hypodermically and chloral hydrate by rectum quieted him for short periods. Respiration was difficult at times. He died twelve hours after admission.

At the necropsy no gross lesions were found. There was a moderate congestion of the meninges. Negri bodies were numerous in the cornu ammonis, and two rabbits inoculated with parts of the brain developed paresis during the third week. In the brains of these rabbits Negri bodies were also found in numbers.

Case 6.—E. A., a white girl aged 13, was bitten, May 20, 1913, by a neighbor's dog which became so irritable and dangerous that on the following day it was shot by a policeman. Neither the owner nor any one else thought the dog had rabies and no report was made to the laboratory. The injury consisted of one punctured wound on the instep of the right foot, the dog's tooth passing through a shoe and stocking. The wound was not cauterized, healed readily, and no further thought was given to the accident.

July 4, forty-five days after the bite, she attended a picnic but came home in the afternoon complaining of a headache and a pain in her throat on swallowing. She was assured by her family physician that there was no connection between this and the bite. She could not sleep that night and on the following day developed a marked fear of water, was very restless and irritable, and was brought to the hospital twenty-four hours after the onset. She was then extremely restless and nervous, with marked hyperesthesia. She could not swallow. Morphin and chloral were administered. Six hours after admission she was seized with general convulsions and died from exhaustion one hour later.

The necropsy showed no gross changes other than congestion of the meninges. Four rabbits were inoculated with the brain. One developed paresis in the hind quarters on the eighteenth day, another became similarly paralyzed on the thirty-fifth day and died on the forty-first. No Negri bodies were found in the patient's brain. In the second, third and fourth rabbits Negri bodies were numerous and relatively large.

Case 7.—L. S. P., a farmer aged 52, was attacked by his own dog, July 1, 1913, thrown to the ground, and badly bitten on the hand and wrist. The hand was severely mangled and there were punctured wounds on the wrist. The wounds were dressed with an antiseptic, but *not* cauterized. Five days later, July 6, antirabic treatment was begun, the examination of the dog's head having revealed the presence of Negri bodies.

July 21, twenty days after the injury and fifteen days after the first injection, the patient's hand and arm became very painful. The pain, which was so severe that he could not sleep, continued for forty-eight hours, and on the 23d extended over his shoulder, back and arms. On the 24th he was very nervous, restless and suffering intensely. On the 25th he had difficulty in swallowing, and he was mildly delirious at times. Paralysis had developed in the arm, and he was extremely hypersensitive to touch. He talked constantly and was extremely restless, though no convulsions were noted. He was from the first given large doses of morphin hypodermically.

On the 27th he became more quiet, paralysis and exhaustion grew more pronounced and he died six days after the onset of the first symptoms. No post-mortem was made.

Of these seven cases, necropsies were held in six. Prolonged and careful search of the brain in Cases 1, 2, 3, 4 and 6 failed to reveal a single Negri body, though many smears and sections were made of the cortex, basal ganglia, cornu ammonis, medulla oblongata and cerebellum. In Case 5 Negri bodies were large and abundant. Brain substance from each case was injected into two or more rabbits and all of these without exception developed a paralysis typical of the disease and died. In the brain of every animal Negri bodies were abundant and easily recognized. The shortest period of incubation in the rabbits was twelve days, the longest thirty-five days.

REPORT OF CASE TREATED WITH QUININ

Case 8.—*History.*—C. B., a white man, aged 73, an itinerant umbrella mender, walked into the laboratory Aug. 29, 1913, and asked for advice about an old dog-bite which had given him a great deal of pain during the past four or five days. He said that five or six weeks before he had been bitten on the right leg by a dog, but, as his occupation made him a frequent object of attacks by dogs, and as he had had "several hundred" during his lifetime, he gave no special attention to this one. The wound healed promptly without medical attention and he had entirely forgotten the incident.
